The causes of vomiting in newly born children are reviewed. Cases of esophageal malformation, esophageal stenosis, cardiospasm (4 cases), cardiospasm with pyloric stenosis and two cases of duodenal obstruction are reported.

Cardiospasm is probably more frequent in the new-born than we have suspected. It should be considered when continued vomiting is present.

These conditions present a fairly clear clinical picture and differential diagnosis is possible especially after careful roentgenological studies. Early diagnosis and treatment before extreme weight loss has occurred will largely relieve the symptoms and reduce the mortality from these causes.

phagus passes through the esophogeal opening in the diaphragm. The term cardiospasm does not seem to be accurate. I do not think that cardiospasm exists in new-born infants. The term cardiospasm should be reserved to designate the type of obstruction occurring in later life and which is dependent upon degenerative changes in

the ganglion cells of Auerbach's plexus.

There is further evidence in support of this view from the fact that there is no true anatomie sphineter at this end of the stomach, and also that these cases do not respond in the slightest to very large doses of atropine. I believe the term esophogeal stenesis to be the correct term to use. The stenesis is caused by various mechanical factors of which dipping backward of the esophagus before it enters the esophogeal opening is one of the most important. Mosher has been able to demonstrate this and other mechanical factors in new-horn habies.

The vomiting of esoplogeal stenosis has cer-

tain diagnostic characteristies. It is a projectile, forceful type of vomiting, often less forceful than the vomiting occurring in pyloric stenosis. There may be evident a metallie type of cough preceding the vomiting. I have repeatedly seen the mechanism that produces this cough in the fluoroscope when a small amount of barium mixture is forced up the esophagus and spills into the traclica. We also have found the absence of the visible peristalic suggestive of this condition.

I have treated these cases successfully by passing soft rubber catheters into the stomach beginning with a 12 or 14F, and increasing to about a 28F. These catheters act as effective dilators. They should be passed about every 12 hours for the first two or three days, then once a day for a few more days. This will cure the stenosis

THE STATE MEDICAL EXAMINER By LEOPOLD BRAHDY, M.D., NEW YORK, N. Y.

CPECIALIZATION may be a conscious narrowing of the physician's field of activity or it may be determined by the nature of his work. The physician on the staff of the Labor Department of any state soon realizes that he is dealing with clinical material not common in private practice. He must answer medical questions seldom raised outside of industrial medicine. The difference in the nature of his cases and of his approach to them differentiates his work from that of other physicians. In addition, his civic status as an employee of the state too often causes him to lose interest in the economic problems of his colleagues and to neglect the medical societies. other hand, the societies composed almost entirely of physicians in private practice have paid but little attention either to the scientifie or to the economic problems of the state physician. Quite regardless of what the future may hold for medical practice, the number of physicians in employ of the state must increase with the rapidly developing social legislation. It is hoped that a brief outline of the clinical work of a physician in a State Compensation Bureau will aid in safeguarding the sense of scientific and social kinship of the state physician and the private practitioner.

The primary function of the mcdícal department of the Compensation Bureau is the determination of the disability of claimants and of the relationship of that disability to the injury or industrial disease.

The efficiency with which this function is performed depends upon three factors: the ability of the examiner, the organization of the department and the cooperation of the referees and of the administration. The qualifications of the examiner are—those of a competent experienced

physician.

The state examiner is frequently required to give an independent opinion on cases, which have been reported upon by able men in the community. It is, therefore, essential that he be a man of more than average competence.

There are many similarities and some differences in the parts of a physician's abilities, which are most needed in private practice and in the

work of a medical examiner.

The determination of disability requires aecurate diagnosis of a great variety of pathological conditions. In every physician's verdict of "disabled" or "has recovered his usual earning capacity" is the implication that he knows the signs, symptoms and course of the patient's ill-Too much emphasis cannot be placed on the need for diagnostic ability. Diagnosis, of course, does not depend on the history and the physical examination alone, Roentgenograms and other laboratory tests are often essential. Teachers of medicine repeatedly warn the profession not to accept the verdict of the laboratory as final, but to interpret the laboratory findings in the light of the clinical picture. To no physician does this apply more forcefully than to a state examiner. He must be able to interpret roentgenograms and other laboratory tests without the laboratory reports. At the same time he cannot neglect the assistance of specialized knowledge and teclinical skill. To make full use of specialists' reports but never to accept their verdict blindly is a fine art born of experience re-enforced by a theoretical knowledge of the laboratory test or specialty in question.

In civil practice, great weight is given to subjective symptoms. Although subjective symptoms must be considered, it is difficult to establish a case judicially unless the diagnosis is based to a large extent on objective signs. The industrial physician must learn to find and evaluate physical signs much more than his colleague in general practice. In the medical literature, the distinction between objective and subjective signs is seldom clearly drawn and where the diagnosis can be made on the patient's statements, the objective signs are seldom described in great detail. By careful observation the medical examiner soon learns to shift the basis of diagnosis in many cases from the clinical history to the physical examination.

This shift in the basis of the diagnosis is only one aspect of the difference between the private practitioner and the state medical examiner. some ways, the position of state examiner requires a specialized knowledge of medicine. The most experienced physician will find himself less capable of doing the work of an examiner than his colleague who has done the work for several In private practice the physician seldom concerns himself with the diagnosis of malingering. He assumes that what the patient tells him is an honest statement. The detection of conscious malingering requires as much skill in diagnosis as is required in many pathological con-The prevention of fraudulent medical claims is one of the problems of industrial medi-Exaggeration is frequently met with in private practice, for it is a natural biological tendency of many individuals to exaggerate their symptoms. When added to this natural tendency, we have the claimants' equally natural desire to make sure that the physician does not underestimate his disability, we have a condition which is often impatiently dismissed as malingering. An understanding of the psychology of the injured claimant is acquired only with experience in in-The differential diagnosis of dustrial work. malingering and exaggeration is of the utmost importance in compensation work but plays so minor a role in private practice that the physician scarcely gives it a thought.

At first sight it may seem that it is a simple step from ordinary diagnosis to the determination of functional capacity. That this step requires training and experience becomes obvious when one observes the diversity of opinions of several practicing physicians when there is no difference of opinion regarding the pathological condition. The practicing physician seldom formulates a judgment as to the handicaps resulting from any particular abnormality. He is concerned chiefly with the diagnosis of the pathol-

ogy to guide the treatment.

When the case is no longer amenable to improvement by treatment, it has little interest to the practitioner but is of paramount importance to the state examiner. A knowledge of the effect of time, use and training on the patient, must be considered as well as the effect of treatment.

Prognosis to the practicing physician means a knowledge of the mortality and of the complica-

tions of diseases. It is a somewhat different prognosis the state examiner must make. What will be the probable earning capacity, in five years from now, of this man with a compressed fracture of the twelfth dorsal vertebra? And of this man who has had both semi-lunar cartilages of the knee excised? The medical examiner must answer such questions in order to guide referees in financial adjustment of cases or in order to guide injured workers in choosing a new vocation.

There is no better illustration of the necessity for accurate diagnosis and prognosis than in the functional disabilities:—the neuroses and hysterias. Some of these cases are helped by ending the litigation at the earliest possible time. The criteria on which to classify functional cases, according to whether the unsettled litigation plays an important role, requires experienced and deliberate judgment. The report of a neurologist may be helpful but the decision must finally rest on the state examiner's experience in such cases.

As in the case of prognosis, etiology is of interest to the practitioner whenever it has any bearing on therapy. The relationship of trauma and disease is a subject of minor interest to the civil practitioner but which the state examiner must study closely. The effect of a blow, a sprain, exposure or an industrial poison on any pathological condition is a more difficult and perhaps as important a subject as their effect on normal tissues.

One phase of the examiner's work is very little known to the general professions—that is, the estimation of schedule losses. A schedule loss is the anatomical or permanent functional loss of part of an extremity or of vision. Any physician with his knowledge of the physiology of joints and muscles can learn this phase of the work. It does, however, require experience before his estimations become reliable.

For the practicing physician to know the facts is sufficient. The state examiner must in addition express those facts clearly and simply. If there is a controversy in a case, he requires the logical mentality to enable him to give a clear account of how he arrived at his conclusions. He must have sufficient self-possession so that the attorney for either side cannot confuse him or use him to becloud the issue.

Even more important than professional ability is the character of the examiner. It is obvious he must possess the moral integrity, never to be swayed in his opinion by hope of personal gain or by friendship. He should have the emotional stability to prevent his scientific opinion from being in any way affected by prejudice or sympathy.

To sum up briefly, the state medical examiner must be a man of sound character who has high professional abilities, who is able to express his opinions clearly and who is experienced in the special requirements of compensation work.

SQUAMOUS CELL EPITHELIOMATA OF THE SKIN OF THE FACE

Report of Twenty-six Cases

By EUGENE F TRAUB, M.D., AND JESSE A TOLMACH, M.D., NEW YORK, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York in Buffalo Wednesday, May 25, 1932

TREMENDOUS strides have been made in our concept of cancer but the fact still remains that the only hope for cure hes in the early eradication of the lesion. It follows quite logically that early chinical recognition is essential In squamous cell epitheliomata of the face this is possible because of the typical appearance that the lesion always presents early in its development Although in the early stages of their growth these malignant tumors are mistaken for such be nigh conditions as infected schreeous cyst, mol luscum contagiosum, infected verruca and granuloma pyogenicum, failure to establish a differential diagnosis can be obviated by watching for the typical clinical signs which occur in squamous The diagnosis of squamous cell epitheliomata cell epitheliomata need not depend upon biopsy Biopsy should confirm rather than suggest the diagnosis for the latter can le and should be made from the typical chinical manifestations essential to the early institution of correct therapy

Most of the chinical descriptions of squamous cell epitheliomata found in the literature, with the exception of a detailed one by Darier, are broad and include, without any real attempt at distinction, the various types of epitheliomata such as bisal, bisal squamous, and squamous

In the twenty six cases which we are present ing we shall emphasize the church signs which were unfailingly present and which served to establish the differential diagnosis

INCIDENCE

Squamous cell epitheliomata of the skin occur more frequently than is generally supposed curate statistics are not always available because of the fact that many eases are treated on the basis of elinical diagnosis without the confirma tion of a microscopic study Among 2,000 eases of general epitheliomata observed in the Mayo Chine from November 1st, 1904 to July 22nd 1915 Broders2 found 256 or 128%, to be squamous cell epitheliomita of the skin. A very in teresting statistical study of skin careinomata based upon instologic sections was made by Borr mann 8 He found the squamous type in four out of six eases (663/3%) of tumors of the upper lip, seventeen out of forty one eases (41%) showed the lesion on the nose and in the naso labial fold, in eight out of twenty-three cases (34%) the tumor occurred on the cheeks, in seventeen out of twenty eases (85%) it was on the ear and in that vicinity, eleven out of thirtyseven (30%) presented the lesion about the eye, and in eighteen out of thirty-four cases (55%) the growth was on the forehead and temples

The same high incidence is reported elsewhere Golden,4 in a report of epitheliomata studied at the New York City Cancer Institute stated that of 173 cases, 68 were of the squamous cell variety, with 46 of these occurring above the level of the neck. Forty three eases were diagnosed as epithelioniata without an histological study.

Montgomery⁵ and Darier⁶ reported a rather high rate of incidence of squamons cell epitheliomata of the skin. In 100 cases of epitheliomata, Montgomery found 63% to be of the squamous cell type, and in a like number of cases observed by Darier in private practice, 50% were found

Lunsford and L Taussig studied the ease histories of patients treated in the out patient department of the University of California for a period of six years Of 100 cases of epitheliomata of the face, excluding the ear, 87% were basal cell and 13% were squamous cell tumors. On the ear, out of nine cases, two or 22% were basal and seven or 78% were squamous. This seems to bear out the general opinion that the majority of the lesions on the ear, particularly when involving the cartilage, are of the squamous cell variety. These authors also believe that epitheliomata of the upper lip and the cyclids, involving the mircous membrane surfaces are generally either of the mixed or squamous cell type.

According to Darier, "the cause of facial localization of the vast majority of epitheliomata of the skin is not known, undoubtedly it is to a considerable extent because this region is the seat of election of senile degenerations and leuco plakin, because it is particularly exposed to traumatisms, to inoculations of infectious germs to the influence of atmospheric factors and especially of light which seems to exert a favoring action (and possibly because the complicated planes of embryonic growth in the face afford a ready opportunity for the misplacement of epithelial cells).

The greatest proportion of epitheliomata en countered on the face is above the angles of the mouth. In approximately 1000 cases of cancer of the head and face, Sutton found that more than 25% showed involvement of the nose alone.

ETIOLOGY

The essential cause of eareinomata is unknown Many of the theories offered are at best purely speculative. Attempts at explanation have been made along various lines, all of which are well

known. Briefly, some of the oustanding theories are as follows:

- 1. Cohnheim's¹⁰ theory holds that tumor growth depends upon displacement of embryonic cells.
- 2. Ribbert's¹¹ theory is a modification of the Cohnheim theory. He believes that the isolation of the cells which are to produce the growth may occur in adult life and that this isolation is brought about by the irregular growth of other tissues.
 - 3. The theory of parasitic origin of tumors.
- 4. Theories of tumor growth based on the effect of irritants.
- 5. Theories of tumor growth depending upon disturbance of the equilibrium of tissues.
- 6. Theories of tumor growth depending upon fundamental changes in the character of the cells.
- 7. Warburg's¹² theory links the genesis of cancer with a biochemical factor, such as a change on the part of the precancerous cell from nutrition by oxidation to nutrition by hydrolysis.

8. Handley¹³ states, in an excellent monograph on this subject, that he has found chronic lymph stasis to be a constant factor in the pathogenesis of cancer.

Menetrier¹⁴ has divided the theories of the origin of cancer into two groups; (a) the parasitic theories, which seek the cause of cancer in a specific living agent reaching the body from without, and, (b) the cellular or cyto-physiological theories, which stress the intrinsic modifications of organs and tissue.

Handley¹³ believes that "these views can be harmonized if it is admitted that various nonspecific infections and chemical and physical irritations, or alternatively, certain congenital lymphatic malformations seen in moles, may set up a chronic local lymphatic obstruction which in the course of years profoundly modifies the vital processes of the surrounding cells. The circulation of tissue fluid is impaired, and in the obstructed district the cells no longer receive their due share of the products of the other cells of the body. They are deprived of the hormones by which the cell society exercises its influence upon the cell individual, and particularly of the hormone which limits cell division."

The great number of conflicting theories is of course the best evidence that our concept of cancer is still in a speculative stage.

DESCRIPTION OF THE TYPICAL LESION

The development of the nodule is usually rapid, beginning frequently as a papular lesion of pinhead size, and reaching a diameter of one to two centimeters in from three to six weeks. After this period, the growth is somewhat slower. In patients under forty-five to fifty years of age it is more rapid than in older people. The typical squamous cell epithelioma of the glaborous skin

begins first as a small grayish nodule covered with a scale or crust. As it increases in extent and depth, the crest assumes a reddish color and may become ulcerated or verrucous. The tumor which develops is hard, firmly imbedded in the skin and yet protuberant. Its raised, bulging border presents a glazed or waxy appearance. The presence of numerous small blood vessels in the border gives the base an acute inflammatory appearance which is characteristic because of its invasive tendency. The upper and outer portion of the border is usually more or less hyperkeratotic and in the central area an erosion appears. The latter develops into a perpendicular ulceration which is irregular, fissured, grayish in color, and bleeds easily even upon slight irritation. The appearance of the lesion at this stage may easily simulate a large infected verruca or an infected molluscum contagiosum. The congestion and vascularity of the base of the growth give the appearance of an infection. On the floor of the central crater there can be seen yellowish-gray granules or material simulating the cheesy contents of an infected sebaceous cyst. This latter substance is composed of horny cells and epidermic globules.

In none of our cases was there evidence of glandular or visceral metastasis within the periods of our observation. This contradicts Darier's belief that the lymph nodes draining the affected area become enlarged early but that generalization in the viscera is rare.

In one of the cases reported here (Case No. 1) the lesion when first seen showed the general characteristics of an infected sebaceous cyst and treatment was given on that basis. The histologic findings of squamous cell epithelioma in this instance were unexpected and emphasized the importance of establishing a differential diagnosis as early as possible, between these malignant growths and sebaceous cysts, infected mollusca contagiosa, granuloma pyogenicum, and infected verrucae vulgaris, with which they are too often confused.

DIFFERENTIAL DIAGNOSIS

The following are lesions for which squamous cell epitheliomata are most frequently mistaken and the method of differentiation is given in each

1. Granuloma pyogenicum. These lesions bleed frequently and freely. They grow slowly and do not usually reach the size of the average epitheliomata observed in our cases. They are more vascular and spongy and are purplish-red in color. The base of the lesion is neither as hard nor as inflammatory as the base of the squamous cell epithelioma, and neither is there a central crater with a verrucoid periphery. A history of trauma is almost always obtainable in granuloma pyogenicum.

- 2. Verruca (infected). These growths usually enlarge more slowly than the squamous cell epitheliomata and are distinguished by a more liorny (warty) crest. The base is not as infiltrated nor as hard as in the squamous cell tumors. No central crater or opening is present in verruca and the lesion does not present the characteristic bulging, waxy borders, with telangications which is seen in squamous cell epitheliomata. As a rule other warts are present.
- 3. Mollusca contagiosa (infected). There is a rather close clinical resemblance between mollusca contagiosa and squamous cell epitheliomata but the former are usually multiple lesions and have not the firm, hard consistency, the inflammatory appearance and the increased vascularity of the base of the latter.
- 4. Scbaceous cyst (infected). While the clinical resemblance of sebaceous cyst to epithelioma is often remarkably close, they can be readily distinguished from each other by the fact that cheesy sebaceous material is easily expressed from the cyst. The cyst is usually below the skin and just protrudes upward, whereas the epithelioma seems to spring out of the skin in spite of its deep inflammatory attachment and fixation. There is no central crater in a sebaceous cyst, no telangiectasia, and no rough, warty crest as in epitheliomata of the skin, and generally the lesions are of longer duration.
- 5. Basal or basal squamous epitheliomata. It is often quite difficult to differentiate the basal or hasal squamous cell tumors clinically from squamous cell epitheliomata but the former develop more slowly and are of longer duration. They are flatter and while they may ulcerate centrally, they do not show the characteristic volcano-like crater with the bulging border of epitheliomata of the squamous type. They may show telangiectasia, and deep infiltration, but the inflammatory appearance and deep attachment of the lesions of squamous cell tumors are more marked.

TREATMENT

We shall consider here the various methods generally employed in removing squamous cell growths, with special emphasis on the treatment which we have found most effective.

- 1. Acid or chemical applications of any kind used cautiously simply aggravate the condition. Effective destruction by acid usually entails severe, extensive and unsightly burns. This method of treatment, we feel, should be discouraged.
- 2. The use of radium or x-ray, except as an adjunct before or after removal, is not advised owing to the refractoriness of the cells to radiation. In treating some of the older patients showing lesions of long duration and slow growth, radiation is sometimes advisable, but even in such instances, unless there is some other contraindica-

tion to this procedure, radical excision should be given the preference.

- 3. Removal by knife surgery is effective but our objection to this method is that there is excessive bleeding, and the frequent necessity, especially in large wounds, of resorting to skin grafting in order to obtain a good cosmetic result. This method also has been criticized on the grounds of possible dissemination of cancer cells through the blood stream, but recent opinions have held this possibility a doubtful one.
- 4. Actual cautery knife destruction of the growth by a criss cross grid leaving the charred area in situ as crust is effective, but eliminates the benefit of a microscopic report on the excised tissue. One cannot always be certain when employing this method that the center of the base is entirely destroyed unless it is overcauterized.
- 5. The electric knife or endotherm removal of squamous cell tumors is the method we favor and have used, with a few exceptions, in this series of cases. Two types of knives or tips are used (see illustration). One, a flat broad-bellied

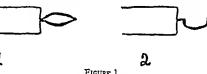

FIGURE 1
Two Types of Electric Knives

knife which is used first to mark the four poles by making stab punctures. This process is then repeated to complete a deep trench about the tumor. The breadth of margin removed about the lesion is roughly the diameter of the growth when the latter does not exceed 11/2 to 2 centimeters; in larger tumors a margin allowance of about 11/6 centimeters is generally safe. After the trench has been completed, the second tip is used. This is a light, flat, sickle shaped wire which is used to cut out the area that has been walled off. If in the dissection a large blood vessel is noted, this is picked up with a small artery clamp, and the handle is then touched with the knife blade, using a coagulating current. In this way most of the bleeding may be prevented, and the base may be carefully excised. It is well to mark the upper pole of the specimen before it is removed, so that the laboratory may definitely report on all borders and the base as to the margin of safety in removal. If the base has not been irradiated after removal, the wound usually heals in about four to six weeks. Radiation delays the healing about one to two weeks. Several of the larger tumors in our cases required an excision that left an operative wound measuring about eight centimeters in diameter. All healed nicely leaving com-

paratively small scars which were as a rule soft and flat, except in their central portion where several had a slight tendency to be thick and hypertrophic. Wherever indicated, these may be reduced with radium or excised. The only disadvantage to this method is the slowness of repair,

FIGURE 3

(a) Typical lesion three weeks old, Case 10. Patient had been splashed by molten lead at site of lesion. (b) Same wound seventeen days after excision. (c) Wound immediately on closing. No skin grafting employed.

and in cases where the excision has been large, this cannot well be hastened. However, its many advantages far overbalance this slight inconvenience.

The twenty-six cases which are included in this report are listed here in table form with descriptions of the special features in each case.

Case No. and Date	Name Sex and Age	Dura- tion	History of trauma	Location	Description of lesion	Histologic report	Trealmont	End τesult
1 Dec. 27, 1923	T.B. F. 68	6 wks.	None	Center of forehead	Typical appearance. This was the first case and was originally diagnosed as an infected sebaceous cyst	Squamous cell epi- thelioma.	Excised surgically with line of ex- cision close to margin of lesion	Patient seen only up to Jan. 7, 1924. Further observation and treatment undertaken by another physician. Result unknown.
2 1924	T. M. 52	6-8 mos.	None	Left temporal region	Typical appearance. 1.5 cm. in diameter.	Squamous cell opi- thelioma	X-rays and radium at first without any benefit. Later wide endo- therm excision	Unknown.
3 Aug. 27, 1925	W.F. F. 86	4 wks.	None	Right side of nose	Raised, red, inflamma- tory nodule with typical waxy bulg- ing sides and features already described.	Squamous cell epi- thelioma	Massive dose of radium. Excision had been refused	Alive and well, five years later. At that time there was a thin white sear at site of lesion.
4 Apr. 26, 1926	S.C. F. 33	5 wks.	None	Right cheek near inner canthus of eye	Typical inflammatory nodule which developed at site of surgical excision, two weeks previously of a vascular lesion	Squamous cell epi- thelioma.	Wide endotherm excision. X-rays to base	Excollent result, two months later. Follow-up letters returned because of chango of address.
5 Sept. 23, 1926	C. E. O. M. 78	9 mos.	None	Left cheek	Large characteristic nodule, 4.5 cm. in diameter. Broken down centrally and discharging cheesy purulent material	Squamous cell epi- thelioma.	Wido endotherm excision. X-rays to base	Patient had had no re- currence four years later at which time he died of other conditions due to "old ago."

Case No. ond Date	Name Sex and Age	Dura- tion	History of trauma	Location	Description of lesion	Histologic report	Trealment	En i result
6 Dec. 6, 1926	P.R. F. 67	6-7 mos	None	Middle of nose	Lesion, attached to underlying bone of bridge of nose, was 2.5 cm, in diameter, typical in appearance, with central crater and markedly inflamed base.	Squnmous cell opi- thelioma.	excision. X-ray	Patient could he followe: up for only 9 months a which time condition wa apparently cured.
7 May 5, 1927	N.D. F. 75	l plus years	None	Righttemporal region	Large typical nodule 4.5 hy 5 cm. in diameter.	Squamous cell epi- thelioma.	excision. X-ray	Excellent cosmetic result Patient well to present date. No evidence of local recurrence. No palpable nodes in field of drainage.
8 May 10, 1927	M.T.F M. 38	3 weeks	None	Center of left upper lid	Nodule 5 by 8 mm. in diameter. Looked like molluscum con- tagiosum, but had central erater, bulg- ing, grayish, waxy sides and many small hloodvessels in base.	cell epi- theliomn	Endotherm excision. Radium to base. Two fivo mg. needles in repair ruhher for two hours	Last seen Decomber 8, 1929 Excellent cosmetic result No local recurrence and no pajpable nodes in field of drainage.
9 Sept. 1927	P.P. M. 34	6 weeks	None	Center of right check	Typical nodule, 7 5 mm by 1 cm. in diameter	Squamous cell epi- thelioma	Wido endotherm excision. No radi- ntion to hase.	Unknown. Patient did not return to clinic
10 Jnn. 30, 1929	H.T. M. 41	3 weeks	Hot lead struck face in course of work		Typical nodulo, 1.75 cm. in diameter	Squamous cell epi- thelioma.	Wide endotherm oxclsion. No radi- ation to hase	Patient alive and well at present time. No ovidence of recurrence locally and no lymph node metastasis.
June 11, 1929	G.G F. 50	10 weeks	Rose thorn hro- ken off in skin, many attempts to remove it. Physician used acid	Left side of nose at border of check	Markedly inflamed waxy lesion of typical appearance,	Squamous cell epi- thelioma.	Wide endotherm excision. Radium to hase	Pntient nlive and well at present time. No local recurrence.
12 Sept. 26, 192	P.E. M. 9 50	5 weeks	Patient squeezed pimple	Leftcheck over malar emin- ence	Typical nodule. 2 cm. in diameter	Squamous cell epi- thelioma.	Wide endotherm excision No radi- ation to base	No evidence of recurrence to date.
13 Oct., 1929	L.N. F. 45	3-4 weeks	None	Near inner canthus of right eye	Typical nodule	Squamous cell epi- thelioma.	Wide endotherm excision. No radi- ntion to hase. Slight keloidal scar radinted later	Alive and well to date No recurrence.
14 Nov., 1929	H.R F. 79	years	Lesion arose on site of previous ly removed lesion thought to be hasal cell epithelioma	"	Typical nodule	Squamous cell epi- thelioma	Wide endothermy excision. X-rays to hase	Alive and well. No recurrence.
15 Apr. 19, 1930	L.W M. 30	. 6 wks.	None	Left cheek near naso- lahial angle.	Typical nodule	Squamous cell epi- thelioma	Wide endothermy excision. X-rays to base	No recurrence to date.
16 Oct., 1930	V.R F. 79	. 18 mos.	None	Center of fore head near hair margin		Squamous cell epi- thelioma	Wide surgical excision and Thiersch Graft	No recurrence to day.

Case No. and Date	Name Sex and Age	Dura- tion	Hislory of trauma	Location	Description of lesion	Histologic report	Trealmeni	End result
17 Oct., 1930	H.B. M. 73	4–5 wks.	Had cancer of tongue five years previously	Right side of neck	Lesion was 1.5 by 2 em. in diameter. Typical appearance. No nodes enlarged. No connection with tongue lesion could be found.	Squamous ecll opi- thelioma.	X-ray only	Only slight responseto radiation. Patientdied of tongue cancer.
18 Oet., 1930	M.C. M. 79	6 wks.	None	Right cheek	Typical appearaneo	Squamous eell epi- thelioma.	Removed by surgery. No radiation to base	No recurrence to date.
19 Apr., 1930	R.J.G. M. 40	6 wks.	None	Center left cheek	Typical appearance	Squamous eell cpi- tholioma.	Wide endotherm exeision. No radiation to base	No recurrence to date.
20 Feb., 1930	L.B. M. 47	6 wks.	Removed with cautery 2 weeks previously when diagnosed as wart. Prompt recurrence in two weeks	Near inner canthus left eye	Typical appearance	Squamous cell epi- tholioma.	Wido endothermy excision. Perios- teum of bone of nose curetted. No radiation to base.	No reeurrence to date.
21 Feb., 1930	M.R. F. 62	6-7 wks.	None	Near tip of nose	Typical appearanco	Squamous cell opi- thclioma.	Wide endothermy removal including cartilage at base to which lesion was attached. No radiation to base.	No recurrence to date.
22 Mar., 1930	C.T. M. 06	4-5 mos.	Had had eancer of lip removed. Had node dis- section of neck too	Left cheek	Typical appearanco No ovidence of direct extension	Squamous coll epi- thelioma.	Surgical removal. No radiation to baso	Patient died one year after romoval of cancer of lip No recurrence on check up to time of death, 6 mos. after our treatment.
23 Apr. 22, 1930	W.S. M. 50	6 mos.	None	Overlying but not attached to right mas- seter muscle	Lesion was 5 cm. in diameter, with typical appearanco	Squamous cell cpi- tholioma.	Excised surgically. No radiation to base	Followed up until Nov. 2, 1930. Patient was well and no signs of re- currence.
24 Nov., 1930	W.C. F. 37	7 wks.	Squeezed pimple	Left cheek	Typical but eovered with bloody pellicle.	Squamous cell cpi- thelioma.	Wide endotherm excision. No radiation to base	No recurrence to date.
25 Jan., 1931	J.G. M. 37	6 wks.	Local ointments and electrolysis to treat sup- posed peri-fol- licular infection.	jaw	Typical but thought by some to be blastomycosis	Squamous cell cpi- thelioma.	Surgical excision and node dissec- tion which showed only hyperplasia and no earcinoma.	No recurrence to date.
26 Apr. 12, 1932	C. F. 69	6 wks.	None	Right tem- poral region	Typical lesion with diameter of 2 cm. Skin about lesion rod because of recent X-ray treatment	Squamous cell epi- thelioma.	Surgical excision and Thiersch graft	Recent operation. Too early to determine result.

SUMMARY AND CONCLUSIONS

1. In all of the twenty-six cases, the appearance of the lesion corresponds closely with the description we offered earlier in this paper.

2. In seventeen of the cases the lesion developed rapidly, within seven weeks or less; in one case it was present ten weeks before coming under our observation; in five cases, the duration was four to nine months; and in three cases, it was present one to two years.

3. The development of the squamous cell nodule is usually rapid, reaching a size of one to two centimeters in diameter in from three to seven weeks. After this period the rate of growth is much slower.

4. We are not able to determine any definite relationship between age and rapidity of growth. It appears, however, that the lesions of longer duration occur in the older patients.

5. Five of our cases present a history of

trauma as the precipitating or contributory agent in the development of the nodule.

6. In nine cases, the lesion was removed by a wide endotherm-knife excision alone, and in eight cases this was combined with radiation of the base. Radium treatment alone was given in one case, x-ray alone in one case and knife-surgery was performed in seven cases.

7. In only three cases were we unable to obtain any follow-up history. In one case (Case No. 17) radiation (x-ray) had little effect on the lesion and the patient died of cancer of the tongue which had been present before the skin lesion. One patient (Case No. 22) died one year after an operation for epithelioma of the lip though there was no local recurrence on the cheek at the time of his death (six months after surgical removal of the tumor). Twenty-one of our cases showed excellent cosmetic results and apparent cures after periods of observation ranging from

two months to five years. Thirteen cases have remained well for at least two years.

8. In no case has wide removal been followed by local return of the lesion and yet the cosmetic results are quite satisfactory. When the scar tissue is not entirely flat, it can be corrected by radiation. ' '

'9. In none of our cases, apparently, have the lymph nodes draining the affected areas been in-

·10. In only two cases was a skin graft performed and in each instance the excision had been done by knife surgery.

11. Radiation was not practiced before removal but in the early cases of this group, removal of the lesion was immediately followed by either x-ray or radium treatment. As this procedure delayed healing and seemed to be of no distinct advantage in adequately removed lesions, it has been discontinued.

A STUDY OF SECONDARY CASES OF SCARLET FEVER

By WM. H. BEST, M.D., NEW YORK

From the Bureau of Preventable Diseases, Department of Health, New York City.

THE isolation period for cases of scarlet fever in New York City is thirty days, providing desquamation has ceased and there is no abnormal discharge from the nose, ear, or mastoid, and no enlarged cervical glands. Contacts are not quarantined, unless exclusion of school children, school teachers, nursery attendants, librarians, and foodhandlers from school or work may be considered as modified quarantine. Such individuals are excluded from school or work until seven days after the termination of the case, unless they remove to another address, in which event they may return to school or work seven days after such removal, provided they show no symptoms of the disease. The isolation period is counted from the day of onset of the symptoms, or in those mild cases where the symptoms are unnoted, the day of the appearance of the rash. The terms "isolation" and "quarantine" are used

in accordance with the terminology of the Public Health Association.

'In order to ascertain whether this period of isolation and exclusion is unnecessarily long, a study of secondary cases developing in the family was made to determine at what period during the convalescence of the primary case secondary cases developed. Of course, it is impossible to prove that the second case in the family was contracted from the primary case, since the contacts being at large could contract the disease from other sources. To minimize this possibility as far as possible, the cases studied were taken in a year in which the disease could not be said to be epidemic, and hence the possibilities of outside contact infection reduced to a minimum.

The annual average for scarlet fever in New York City for the five year period, from 1926 to 1930 was 10,737. Therefore, a year was selected in which the number of cases reported corresponded approximately to this average.

There were 11,357 cases reviewed. To these 11,357 cases there were 37,788 contacts—that is, members of 'he family or household. Of course, not all of these contacts were potential cases of scarlet fever, since a certain percentage of them had had the disease and should be considered as immunes. It is impossible, however, to determine the exact percentage of such immunes, since, not anticipating such a study, the histories do not include this information. However, to work out a comparative tabulation as to the percentage of secondary cases developing during the various intervals of the primary case this is not important.

Among the 37,788 contacts a total of 901 secondary cases developed. In 850 secondary cases the primary case was uncomplicated and terminated on the usual 30th day or thereafter when desquamation had cleared up; whereas 51 were secondary to a primary complicated case (discharging ear, mastoid, nasal, enlarged glands) which continued beyond the usual 30-day period, and was not terminated until the complication had cleared up. The tabulation, therefore, shows the secondary cases which developed between the 30th and 37th day, the limit of the incubation period, in the primary uncomplicated case; and also the secondary cases which were presumably infected between the 30th day and the day of termination of the primary complicated case.

TABLE I

		Secondary	Per cent.
	Contacts	Cases	Cases
Under 5 years	4,155	299	7.2
5 to 15 years	9,615	539	5.6
16 years and over	24,018	63	0.26

Table number one shows the percentage of secondary cases developing among the contacts in the various age-groups. This might suggest that the isolation period of cases of scarlet fever to whom the contacts are 16 years and over might receive more favorable consideration in the imposition of quarantine than if the contacts are of the age-group under 16 years. However, an isolation regulation based on this would be impracticable in a large city, where the regulations must of necessity be uniform for all classes.

Table 2 shows the diminishing percentage of secondary cases infected during each four-day period after the onset of the primary case. It is interesting to note the uniformity of the decreases in the "uncomplicated" and "complicated" groups alike. In both groups, over 50% of the secondary cases occurred in the first period (less than 7 days). Since the complications in scarlet fever occur for the most part in the later stages of the disease this factor should have no bearing on the percentage rates of the two groups in this period.

	TA	BLE II		
No. of Days Between Onset of Primory and Ut Secondary Cases No	Seco scomplic . Coses	ndary to oted Primory Pereentoge	Secon Complica No.Coses	ndary to led Primary Percentago

27-30 "	8	.01	2	.04
31-37 "	8	.01		
(uncomplicated primary)				
31 days and over			5	.10
(until primary com- plicated case terminated)				
TOTAL	850		51	

The large number of secondary cases occurring in the first period as contrasted with the later periods is due to the fact that we can rarely hope to get the case isolated less than the fourth day after the onset; and by that time the exposure to the other members of the family has taken place. The secondary cases in this period, therefore, were contracted from the primary case at or about its onset.

Many cases are not reported promptly and hence the delay in isolation accounts for the still high percentage (20%) in the 7-11 day period. There are also to be considered those mild cases that go undiagnosed and are not detected until desquamation occurs. It not infrequently happens that the primary case is discovered only after the secondary case is reported.

In the "uncomplicated group" the percentage of secondary cases is reduced to 2% and 1% respectively after the 21st day. This would indicate that the great majority of uncomplicated cases of scarlet fever are free from contagion after 21 days; whereas in the "complicated group," while the percentage rate continues to decrease, it is more than double this between the 21st and 30th days, and it is usually about this time that the complications arise.

The eight secondary cases recorded between the 31st and 37th day in the "uncomplicated group" need further explanation. Four of these cases should really have been tabulated in the "complicated group" since a complication was later discovered in the primary case, although not known to exist at the time the primary case was terminated. In one instance the primary case was discharged from the hospital in accordance with our regulations, but within one week after discharge three cases developed in the family. Examination of the nose and throat of this child showed an ulcer on the septum of the nose from which a pure culture of streptococcus haemolyticus was obtained. In another instance one case developed in the family within a week after discharge from hospital. The nurse on visiting noted a slight nasal discharge in the case recently home from the hospital. Nasal cultures were reported as positive for streptococcus haemolyticus. Of course, in differentiating between "uncomplicated" and "complicated" cases on a basis of mucous membrane discharge, the human equation will always enter in and certain cases will be terminated and released prenaturely. However, this will prevail irrespective of whatever may be the period of isolation.

During the first five months of 1932 the incidence of scarlet fever in New York reached epidemic proportions and our contagious hospitals became greatly congested. To relieve this overcrowding a modification of our regulations was made whereby uncomplicated cases over 17 years of age were discharged on the 21st day after onset. This released only that group who were for the most part beyond the school age; hence, with the exception of the younger group in the home, they should not be a menace to the community at large since their associations would be for the most part with the older age-group. Two hundred and thirty such cases were discharged from our contagious hospitals up to June 1st. All these cases were followed up and in only one instance was a secondary case discovered. This case, an adult, was discharged from hospital March 29th, and her daughter, age 10, came down with scarlet fever April 2nd. The history of the primary case is interesting, since, although it was discharged as an uncomplicated case, subsequent events proved it to be a complicated case. The primary ease had a slight discharge from the ear while in the hospital, which had cleared up several days prior to leaving. However, the day after arrival home the ear started discharging again.

SUMMARY

- 1. 11,357 cases of scarlet fever were reviewed.
 2 901 or about 8% of these cases were secondary cases.
 - 3. There were 37,788 contacts.
- 4. 901 or 2.4% of the contacts developed scarlet fever.
- 5. Of the secondary cases 56% occurred within one week after the onset of the primary case and were in all probability contracted either from the same source as the primary case or from the primary case before its isolation.

6. The susceptibility of the age-group 16 years and over is comparatively slight.

7. There is a gradually diminishing infectivity in "uncomplicated cases" up to the 21st day at which time the majority are not infective.

8. There is a gradually diminishing infectivity in the "complicated cases" up to the 21st day at which time, although the decrease continues slightly, the infectivity is twice as great as in the "uncomplicated cases." This is probably due to the complication which in most instances arises at this period of the disease.

Conclusions

1. Since the infectivity of desquamation is an obsolete theory, cases of scarlet fever may be terminated without regard to its presence.

2. The few cases in which the contagium persists after the 21st day do not warrant the thirty day isolation period with its concomitant loss of school time for the case and contacts in school children and school teachers, and the economic

loss in business individuals.

3. On terminating scarlet fever a careful examination should be made to determine the presence of a complication, such as nasal discharge, discharge from the ear or mastoid, broken down glands, or cervical glandular enlargement which usually denotes persistence of throat and pharyngeal infection.

4. "Uncomplicated cases" may be terminated on the 21st day with but little danger to the community, or on the 25th day with no greater danger to the community than terminating on the 30th

5. "Complicated cases" should be isolated until the complication has cleared up, unless it can be demonstrated by culture that the discharge is free

from contagium.

6. With a twenty-one day isolation period, school children, school teachers, nursery attendants, and librarian "contacts" to scarlet fever (the first being the most susceptible age-group and the second, third and fourth coming into contact with the most susceptible age-group) should be ex-

cluded from school or work for seven days after the case is terminated.

7. Where the "contact" ceased to be a contact (removal of contact or case, or death of case) prior to the termination of the case, an additional seven-day exclusion should be enforced.

THE DOCTOR'S VACATION

The best vacation consists in doing what one likes best to do. The successful doctor continues in practice because he likes both the work and also the associations which go with it. When he takes a vacation, he lays aside his responsibility for individual sick persons, but he clings to the associations which go with his profession, and practices them more actively than ever because he has the leisure to do so. He attends outing meetings of his county medical society, and group meetings that combine science with pleasure, as does the Lake Keuka Medical Association in the central Hundreds of doctors will part of the State. spend their vacations in groups which combine foreign travel with medical instruction. That vacation is profitable and pleasant which increases the doctor's ability and gratification in the practice of medicine.

EVERY DOCTOR A HEALTH OFFICER

The March 27th issue of Health News, the weekly publication of the New York State Department of Health, contains the following extract from a letter of a rural physician, who, as the local health officer, had made a report on an epidemic of influenza in his town:

"In making this little study of the flu 'on my own,' I became more convinced than ever that private physician and health officer are two distinct jobs. If I took pains to get the record accurate I had to watch that I did not overlook something about the patient. If I gave my best to the patient, I always forgot something about the record. The physician is an individualist interested in his patient above all else. looks in mild contempt on the statistics and graphs of the health officer. Trained to minute detail he does not find it easy to think in terms of mass trends and mass prevention. The health offieer trained to broad vision finds it hard to focus his attention on a single unit. Each is a big job. Together they are too big for any one man. Any man who wants to, can do either; but only rarely will he wholly succeed

The special importance of this quotation is the various interpretations which have been

put upon it.

Although Health News did not commend this quotation, yet it did commend the author—the only practitioner listed in his town—for his excellent public health work, and especially for an educational article on influenza, which he prepared for the local newspaper. However, the quotation is a good argument for collective action in public health through the establishment of county health departments, which is a major project of the State Department of Health, and of Governor Roosevelt's Health Commission. (See this Journal October 1, 1931, page 1209; January 1, 1932, page 30; and February 15, 1932, pages 214-222.)

A strong argument for individualism in the practice of medicine is set forth by the Ohio State Medical Journal for July, 1933, in the following editorial comment on the quotation, from

Health News:

"The difficulties encountered by the health officer illustrate the inherent evils in any system of medical practice which would not permit the physician to devote his entire attention to the welfare of his patients. No physician can render effective medical care if shackled with too much red-tape or forced against his wishes to follow meehanized, stereotyped methods which may not meet the requirements of individual cases.

"In this pertinent analysis of the difference in viewpoint and responsibility of the physician treating his patient as an individual, and the health officer serving the public generally, there is found a most convincing argument in favor of the practice of medicine on an individualistic basis, and against the organization of medical practice in accord with the principles of mass treatment and mechanization."

Both Health News and the Ohio Journal give the impression that the duties of the health officer are incompatible with those of the family physician. They are incompatible in only one respect-that of police control in epidemiology and in sanitation. The Laws of New York State deal with that conflict by imposing the duties of policing and the proseention of delinquents on the board of health, thereby relieving the physicians of the greatest source of unpleasantness in connection with his office. So far as a sick patient is concerned, there need be no conflict between the doctor and the health officer. All epidemiological facts have a direct relation to the welfare of the patient and his family; and the more the doctor knows about the diseases that exist in his neighborhood, the better can he care for his individual patients.

The members of the medical profession of the State of New York are receptive to the idea of participation in those forms of public health work which have long been regarded as peculiar to the health officer. They are coming to regard the health officer as a speculiation of the work which have long been regarded as peculiar to regard the health officer as a speculiar or whom they may call for either diagnosis or treatment; but those in general practice are also realizing that they are competent to handle the greater number of public health problems which arise in their practice.

There has been a tendency for health departments to develop a system of public health practice that is apart from the individual practice of medicine. Family doctors have been too willing that public health physicians should displace them in epidemiological investigations and even in the care of the sick. But the trend now is to restore the family doctor to his rightful position as medical advisor in giving all phases of medical attention to all elasses of persons. The time is coming when every doctor will be a health officer to his families. The attitude of personal liberty and independence in thought and action impedes the physician in his prevention work just as it does the school teacher and the pastor. The family physician is the educator who will inspire the people with a new attitude of cooperation with their family doctors in public health work.

MEDICAL PROGRESS

A Simple Method of Treatment for Leg Ulcers.-All chronic leg ulcers, says Paul Kahn, writing in the Münchener medizinische Wochenschrift of April 21, 1933, develop under unfavorable conditions of circulation, such as chronic stagnation and edema. Whatever the cause of this, in every case lymph containing new toxic products of metabolism passes out from the obstructed lymph vessels and thus permeates the subcutaneous tissues with injurious metabolic products which under normal conditions would be carried away. The chronic edema hinders the venous return flow, and the circulation lying beneath it in the vicinity brings to naught any least tendency to healing, with the end result that the ulcer becomes stationary. Hence the chief consideration must be to get rid of the chronic stagnation around the ulcer, which has as a rule caused induration of the connective tissue, by stimulating new vessel formation and by improving circulatory conditions, thus bringing about a more rapid removal of the products of tissue destruction. On the other hand, this stimulation serves to vascularize the formation of granulations, which constitute the basis for the epithelization of the ulcer. Kahn attains this end by the old time, but forgotten, method of circumcision combined with application of ointments. At a distance of about 1 cm. an incision is made around the ulcer, penetrating the skin and going deep into the subcutis. Beyond this point the skin is scarified for some distance, as far as signs of induration can be established. The more or less copious bleeding that follows relieves the boggy tissue; harmful products of metabolism are swept away, new vessels begin to form and fresh granulation tissue fills the old defect. A sterile dressing is applied and the ulcer left to itself for a few days, after which in most cases it will have fully cleaned up. Occasionally wide tissue necroses require to be removed by wet dressings before the circumcision is done. After the ulcer is clean, a systematic course of stimulation is begun, with a combinaton of scarlet red and balsam of Peru in the form of a salve, which has been found especially effective. In a relatively short time large defects have been filled in with fresh granulations and have quickly skinned over. Although the number of cases in which this method has been tried is not large, results have been most gratifying. No specific selection of cases was made. Ulcers of various etiology and of great depth and extent have alike been subjected to treatment, all having in common the fact of a history covering one or more years, during which various forms of treatment had

been used unsuccessfully. The method is so simple that it can be carried out by any practitioner even without a large instrumentarium. The time required for healing is short compared with that of other methods, and the permanent results in the author's cases have been excellent.

The Demands Made upon Surgery in Cancer of the Rectum.—The site of cancer of the rectum, its usually solitary growth and the lateness of distant metastases, according to Otto Goetze, all favor the development of a standardized technique, the results of which today are increasingly satisfactory and show a gratifying permanence. Surgery is universally the indication, roentgen treatment having been proved totally impotent to produce cures. Since 1931 Goetze has been using a new modification of the sacral method of approach, which he finds considerably safer than the abdomino-sacral method, provided there is the same careful selection of cases and that the same standard of operability is adhered to. Its principle is based on the fact that after resection of the coccyx it is easy, by going behind the fascia visceralis pelvis and the arteria sacralis media, to push on upward over the promontory and open the lateral Douglas' pouches, right and left on the mesocolon, from behind. In this way one can arrive at the same site of the exposed vascular cord of the arteria haemorrhoidalis superior as by the abdominosacral method, and with the advantage of not touching the cancer on the way. The old method forced a way through the glandular region near the rectum, which is infiltrated with cancerous growth, and in which it is necessary to tie, one by one, innumerable branches of the superior hemorrhoidal artery, on the entire posterior surface of the rectum. In the new method, on the contrary, one can tie the arterial trunk with a single ligature above the outlet of the arteria colina ima, that is, above Sudeck's critical The method has also the advantage of opening the abdominal cavity in the region of the bony pelvis, in other words at the passive part of the abdominal wall, while the abdominosacral operation is carried out in the region of the active muscular walls: hence in the sacral method abdominal breathing is to a great extent maintained; this results in much less shock to the intestine and to the bloodvessels of the splanchnic region, and the injury to the circulation is considerably less, since the blood dammed up in the collateral circulation can be more readily mobilized again. The abdominosacral route, however, has one clear advantage, in that it frequently can establish visually whether there are metastases to the liver,

which the sacral route cannot do, there exists, therefore, greater danger that with liver metastases present the surgeon will do a local radical operation where no hope of permanent cure remains, which is contrary to the accepted concept of correct surgical procedure. This concept is, however, untenable, the question must be answered from the clinical and not the anatomical standpoint, and even though the patient must die eventually from cancer of the rectum, he is en titled to the relief of a pallintive operation despite his liver metastases, provided he still has some power of resistance left Goetze has produced total permanent cures in 34 per cent of 100 cases operated on, local cure without recurrence in 20 per cent, 10 per cent died of local recurrence within 3 years, 25 per cent with artificial anus gained 1 year of life, and only 10 per cent did not survive operation -Deutsche medizinische Wochenschrift, April 21, 1933

Heart Disease in General Medical Practice -I V DePorte presents a preliminary report of a survey conducted by the New York State Department of Health with respect to the morbidity from heart disease in the State, exclusive of New Statistics show that heart disease is York City the leading cause of death in this country 1929 almost a quarter of a million deaths in the registration area of continental United States were ascribed to cardiac diseases The death rates of the forty-six registration States ranged from a minimum of 90 per 100,000 in Oklahoina to a maximum of 304 in Vermont The morbidity survey in New York State was commenced in January, 1931, and includes 1 934 cases, 933 miles and 1,001 females The distribution of the patients by age was as follows under 40 years, 27 4 per cent, between 40 and 60 years 30 5 per cent, 60 years and over, 42 1 The average age was 51 5 years and the median age 55 7 years. The males were, as a group, younger than the females Of the former 24 7 per cent were under 40 years, of the latter 299 per cent The average age of the males was 529 years, the median age 577 the average age of the females, 503 years and the median age 535 The leading etiological fac tors were rheumatic infection, 272 per cent, hypertension, 201, arteriosclerosis 88, syphilis 46, congenital syphilis, 24 In 116 per cent of the cases the etiology was unknown The pro portion of syphilitic heart disease among males was three times that among females A definite statement of pathological changes was made in 1 826 cases Damage to the valves was indicated in 487 per cent, damage to the myocardium in 289 per cent, and to the coronary vessels in 198 per cent Coronary disease was more prevalent among males, while valvular disease and damage to the myocardium were more prevalent among females The proportions were coronary disease

in 237 per cent of the males and 16 per cent of the females, valvular disease in 45 per cent of the males and in 521 per cent of the females, and in 521 per cent of the females and in 30 per cent of the females. Dam age to the coronary vessels was of prime importance in the arteriosclerotic and only of lesser importance in the hypertensive type—American Heart Journal, April, 1933, vill, 4

Experimental Effect of Tobacco and Nicotine on the Coronary Debit -In the course of studies carried out on the isolated rabbit heart, Ch Linbry, J Walser and L Deglinde made the following observations with reference to the effects of tobacco and nicotine (1) An identical effect is produced by a maceration of tobacco and a solution of nicotine with an equivalent amount of meotine (2) Weak doses (2-5 drops of a 1 per cent nicotine in 1 liter of Ringer's solution) uniformly caused an increase of the coronary debit varying between 30 and 60 per cent of the initial figure Medium doses (12 20 drops of the same solution) uniformly produced an increase of the coronary debit, varying from 5 to 20 per cent of the initial figure Strong doses (20 100 drops of the same solution uniformly caused a diminution of the coronary debit, which fell from 10 to 20 per cent below the initial figure (3) The variations of the coronary debit are independent of modifications of rhythm and amplitude of the cardiac contractions. In fact, at the time of passage of the strong doses, there was observed despite the considerable increase of amplitude of the heart beats and the acceleration of the rhythm, an actual diminution of the coronary (4) The difference in intensity of the vasoconstrictor and the vasodilator reactions is quite interesting. When the latter reactions are revealed by an increase of debit amounting to 60 per cent of the initial figure, the former do not exceed 20 per cent. We see in this fact a fresh proof of the considerable predominance of the vasodilators in the coronary innervation. Nic. otine therefore exerts a strong vasodilator action when used in weak doses and a weak vasoconstrictor action when administered in strong doses, at least so far as experimental administration The authors raise the question whether the nicotine concentrations used in the experiments approximated those in the blood of smokers, they are inclined to think this is the Lee estimated that 50 per cent of nicotine passes off in the smoke A moderate smoker smoking 10 cigarettes a day thus absorbs about 125 mg nicotine, which, diluted in 5 liters of blood would make 6 drops per liter. In such dosage the nicotine undoubtedly does not exert any constrictive action on the coronary arteries nor does double this dosage. It would seem that in the mechanism of crises of angina related to

tobacco intoxication the coronary vasoconstrictor element plays a negligible rôle, whereas the toxic effect upon the nervous elements of the cardiac plexus is extremely important. — Bulletin de l'Académie de Médecine, April 25, 1933.

Tests with Reference to Curtailing and Transposing the Time of Sleeping.—Th. Stöckman makes a report in the Münchener medizinische Wochenschrift of March 17, 1933, of a series of observations he carried out in 15 adolescents and adults, all of whom were asked independently to check up on their best sleeping hours. A lower sixth form school boy in rather poor health, who could consequently not meet the demands of his grade, studied late at night and then slept as late as possible in the morning; he observed that the longer he slept, the worse he felt and the more disinclined to study. Changing his habits and beginning to go to bed early he soon discovered that if he took a long sleep before midnight he required less sleep and could curtail his sleeping hours. Finally he observed quite definitely that sleep between 7 and 11:20 p.m. brought the maximum of refreshment to body and mind, and that he actually needed no further rest when he took this time for sleep. similar observations are outlined in detail, as examples of an experience that was common to all the 15 persons, each watching himself independently, namely, that their best sleep was between 7 and 11:20 p.m. The precise time of awaking varied somewhat. One boy awoke regularly on the tick of 11:20, of his own accord, and then worked night and day in perfect comfort. conditions of the experiment were sufficiently elastic to adapt themselves to the individual cases. No tests were made in children. Stöckmann takes occasion to emphasize the "double value" of sleep enjoyed before midnight.

Biological Treatment of Hydatidosis in Man. --According to G. Pennetti all the modern biological methods of diagnosing hydatidosis in human beings are founded on the conception of antibodies circulating in the blood of carriers of cysts, the production of these antibodies being related to the vitality of the cysts; when the cyst dies, the reactions become negative. At the present time treatment may be regarded as exclusively surgical. But even simple aspiration of the hydatid liquid involves the danger of producing anaphylactic shock, and it has also been proved With the idea of immunizing the inadequate. patient against the hydatid toxin, which is dialyzable through the membrane of the cyst itself, Ymas Apphatic of Buenos Aires in 1932 prepared from the cystic fluid, by the addition of formol, a substance which he named anatoxin, of which he distinguished a number of different types, according to the amount of formol present. Experiments proved that with a formol content

of ½ and of ¼ per 1000 (anatoxins I and I) the maximum antigenic property is obtained. Treatment begins with a subcutaneous injection of 2-3 c.c. anatoxin Type I every 6-8 days; the third injection is of Type J, of which progressive doses of 5, 6, 7, 8, 9, and 10 c.c. are given, at intervals that vary according to the rapidity with which specific antibodies disappear from the blood. In the 3 cases thus far treated, 13, 23, and 19 injections were given, containing respectively a total of 100, 196, and 168 c.c. anatoxin. third case was particularly instructive, in a patient already operated on 8 years previously for cysts of the left lobe of the liver; these had recurred, and an additional cyst had appeared in the right iliac fossa. The disappearance of reactions after 19 injections remained constant; the cystic tumor diminished in size and increased in consistency. At operation 4 live cysts were removed, which together constituted a mass as large as the head of a fetus. The interest of the case lies in the demonstration of the undoubted antianaphylactic action of anatoxin in the presence of live cysts. The method merits a wider use, since if its curative action is confirmed, it will shed new light on the biologic and therapeutic problems of human echinococcus.—Riforma medica, April 8, 1933.

Tetanus with an Unusual Early Symptom.— With the object of drawing attention to a lone symptom of tetanus which may confuse the diagnosis, especially in the presence of old minor injuries, Pierce H. Leavitt reports the following case. A boy 13 years of age was admitted to the hospital on May 26, 1932, for abdominal symptoms which had lasted for several days. Physical examination showed a well-developed and wellnourished boy, who was suffering with occasional cramp-like pains in the abdomen, lasting a few seconds and referred to the epigastrium, but the epigastric region was not tender. There were tenderness and resistance and the suggestion of a mass in the lower right quadrant. A diagnosis of acute appendicitis was made and operation was performed under avertin and gas-ether anesthesia. The appendix, four inches long, was hard, red and engorged. On May 27th the patient continued to have attacks of occasional irregularly timed abdominal pain, mostly centered about the wound. As there was no relief from the nausea and vomiting on the following day, enterostomy was advised and performed. On May 29th the cramps were still present, coming about The original every twenty to thirty minutes. wound was clean and the enterostomy was working well. About 2 a. m. on May 30th the patient suddenly complained that he could not open his mouth to drink water. Some slight stiffness of the neck was found. Antitetanus serum was administered, and later avertin for convulsions. This worked so well that the author says he

would use it in other cases. A reconsideration of the patient's past history revealed that five or six weeks previous to the onset of the abdominal symptoms a splinter entered under the nail of the left mid-finger. After removing the splinter the area became mildly septic and a doctor had evacuated the pus. The patient also told about a wound from a B.B. shot received in the right thumb six or seven years ago. The shot could be felt under the skin and the doctor removed it. The wound became mildly septic but healed well. It must be assumed that the finger and thumb were the source of the infection. The classical symptoms of tetanus were not present until very late. The patient had a stormy convalescence for three days after the symptoms of tetanus appeared, and then gradually recovered .-- New England Journal of Medicine, June 1, 1933, ceviii, 22.

Problems and Aims of Bioclimatology .-An increasing number of physicians, says F. Linke, are waking up to the value of the 3 active remedies offered by nature, namely, light, air, and environment, to the study of which the new science of bioclimatology is dedicated. It is particularly difficult, however, to bring to light through statistics the often quite concealed relations that weather and climate bear to physical health. One must really be both a physician and a meteorologist to do this successfully. The most urgent task is that of measuring the actual amount of heat given off into the surrounding air by an individual, and the extent to which this depends on the wind, air temperature, and sunshine, as well as upon the clothing. The physical processes of the body should be studied from this point of view. Individual differences would at once be discovered, which would lead to a better definition of the concept of "constitution"; also individual variations would be established, which are probably related to the susceptibility to disease. Then the effect of masses of air of different origin would have to be studied experimentally and statistically, and in addition the effect of the local climate, which is dependent largely on subterranean conditions, and on proximity to mountains and woods. It is already recognized that in certain cities and in other regions some persons never feel well, and it would be economically advantageous not only to business concerns and large real estate promoters but also to insurance companies to understand these processes exactly and, so far as is possible, to bring these sensitive individuals into a climate that is properly adapted to them. In view of the exhausting effects of the climate in many large cities located in river valleys, studies are well justified with reference to the physical and chemical constitution of the air in such places. After gaining an insight into the remarkable capacity possessed by the healthy

organism of maintaining its heat, mineral, and gas equilibrium, it is reasonable to conclude that the sick organism works less exactly and is on this account more or less at the mercy of external influences of a chemical, electrical, and bacterial nature. Some organic or psychic defect lies at the bottom of every case of "meteoropathy." A rich field of investigation lies open, therefore, to those workers who are prepared to devote themselves to research in this field of bioclimatology. — Deutsche medizinische Wochenschrift, March 31, 1933.

Shock Syndrome in Mercuric Chloride Poisoning.-H. V. Moon and B. L. Crawford, writing in the Archives of Pathology, April, 1933, xv. 4, report the case of a man, aged 39, who had swallowed 175 grains of mercuric chloride in tablet form. He walked to the hospital about thirty minutes later. His most pronounced signs and symptoms were those of mental confusion and profound shock. There was no evidence of heart block or of disturbance of the contraction inpulse. There were no marked gastrointestinal symptoms. He voided urine only once about two hours after admission. From profound shock he went gradually into coma and died at the end of thirty-seven hours. At post-mortem the outstanding histological features were necrosis of the tubular epithelium, acute degeneration of the liver, and widespread capillary congestion, capillary hemorrhages and edema, especially of the lungs. The chambers of the heart were not dilated. The valvular orifices were of normal size. The valves showed no defects, and the myocardinm was firm and of normal color. The heart showed no changes of any kind which would make cardiae failure seem probable Search was made for evidence indicating whether the circulatory failure resulted from cardiae deficiency or from injury to the capillaries. Moon and Kennedy called attention to gross and microscopic tissue changes in traumatic shock. Post-morteni examination in human cases and in shock produced experimentally in dogs showed widespread capillary dilatation and congestion, edema, especially of the lungs, and petechial hemorrhages in serous surfaces. These findings corroborate the explanation that shock is due to capillary damage Landis found that injection of such agents as 10 per cent alcohol or 1:10,000 mercuric chloride solution caused injury to the capillary walls similar to that caused by ethyl carbamate (urethane). They markedly increased capillary permeability. Capillaries treated with mercuric chloride were seven times more permeable than normal capillaries. Evidently mercuric chloride may produce capillary damage similar to that caused by other poisons; as such it produces the same circulatory phenomema and the same gross and miscroscopic changes as are found in shock.

LEGAL

MALPRACTICE—FOREIGN BODY—PHYSICIANS HELD BLAMELESS

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

Several years ago a case was carried to the highest court of one of the northwestern States, in which a decision was made on two very important points in the law of malpractice. The facts of the case must be stated in detail for a proper consideration of the court's ruling.

A certain young woman was married in 1919. In the year 1917 she had undergone a surgical operation for appendicitis. In the latter part of the year 1919 she gave birth to her first child. A second child was born in June, 1921. In the summer of 1920, after the birth of the first child, her health was not good and she called Dr. K, her family physician, who determined that an operation was required. sent her to a hospital, and called into the case a Dr. H, the chief surgeon of the hospital. The surgeon agreed that an operation was indicated by the patient's condition and it was arranged. Dr. K was present at the operation, but according to the testimony did nothing except assist under the direction of the surgeon. An incision was made on the right side and the kidney was found to be infected and distended to much greater than normal size, and it was removed. In the opinion of the operating surgeon, the kidney infection was of a tubercular nature. Account was taken by the nurses of sponges, packs and instruments used, a record made and the count found to be correct. The abdominal cavity was not entered by the surgeon during the operation. The wound was very slow in healing.

The next June, in 1921, the patient gave birth to a second child. At about that time the incision made by Dr. H reopened, and a considerable amount of pus was discharged. Her family doctor was called and advised hospitalization. She again went under the care of the surgeon, Dr. H, and he operated to relieve a pus condition of the pleural cavity, resecting a rib. During this operation a thorough exploration was made of the operative field of the 1920 operation and a pus cavity was found and drained. No complications were attributed to the drainage of the pleural cavity.

The woman's condition did not improve, but at the end of about three months she was taken home from the hospital, and she died within a week thereafter. A foreign body was found

by her husband two days before her death and removed by him from the old incision of the 1920 operation. According to his testimony, while dressing the wound he "noticed just like a fuzz there, and I took a cotton batting and let the water drop on there and wash it out. It wouldn't come out, so I took a toothpick and I picked on there trying to get that away, but when she had to cough when I took that away, it stuck out not even half an inch. I didn't know what it was, though, so I took hold with two fingers and pulled on there. She did not notice that. Then I had it out a little I didn't know what to do. I knew that the doctor was not home, so I pulled it There was a whole lot of pus came out after this was out, and then afterwards the stool came out; it was open." The foreign body which was removed was upon the trial put in evidence and was a gauze pack in the form of a roll, about seven or eight inches long and an inch and a half in diameter.

The husband as administrator sued both of the doctors and also the hospital, charging them with negligently causing the death of his wife, and seeking damages. Upon the trial the case resulted in a non-suit as to the hospital before the case was sent to the jury. After all the evidence was in, the court sent the case to the jury as against the two doctors. The jury brought back a verdict specifically finding that the gauze pack had been left in the abdomen by the defendant Dr. H, and that both Dr. H and Dr. K had failed to use proper care, as a result of which death had followed. Damages totalling \$10,000 were assessed against the doctors, and from the judgment entered on the verdict an appeal was taken. The higher court considered the record before it and ruled that the lower court should be reversed.

The appellate court first considered the question as to whether there had been any liability shown on the part of the family physician. No claim had been made that he had been negligent in his diagnosis, and no claim had been made that he was negligent in recommending Dr. H. A claim was made that it was the duty of the family physician to supervise the nurses and to generally direct the operation, but there was no evidence to support that contention. The court, in ruling

out the case as to Dr K, the family physician of the patient, said

'Assertion, insumation, argument and innucudo cannot supply the place of evidence When the nurses and physicians were assembled in the operating room of the hospital, they were not there to prepare for a lawsuit, but were engaged in an attempt to relieve human suffering and save human life, and, throughout this case there is not a scintilla of evidence to show that anything was done or omitted to be done, that is usually and ordinarily done by surgeons exercising that degree of care, diligence, judgment and skill which surgeons in good standing of the same school of medicine usually exercised in the same or similar localities like, under like or similar circumstances. having due regard to the advanced state of medical and surgical science at the time of the operation on August 10, 1920, except as hereinafter On the contrary, the evidence excluding the presence of the pick discloses that both hospital staff and surgeons exercised the highest possible degree of carc, both at the time of the operation in August, 1920 and at the second on-Under the undisputed evidence eration in 1921 in this case, if it should be established that the pack in question was left in the body of the deceased on August 10, 1920 Dr K can in no sense be held legally responsible thereof Standards of duty for a family physician attending an operation under circumstances appearing in this case cannot be established by argument or asser-What constitutes ordinary care in a case such as this is to be determined by the testimony of those who know what it is, not as a matter of common knowledge"

The court in its opinion then proceeded to consider whether there was sufficient evidence that the surgeon had left the pack in the deceased's body so as to hold him to liability. It was found that there was no question that the pack had been in fact removed from the body of the deceased and that there was at the time of its removal an opening from the ahdominal cavity through the peritoneum to the orifice made by the incision of the 1920 operation. If there had been no appendectomy in 1917, the proof would have been clear that the foreign substance was left in in the course of the 1920 operation was undisputed evidence that Dr H in neither operation entered the abdominal cavity There was also evidence that packs of the kind in this case are ordinarily used in appendical operations, and further that sterile gauze as this must have been might remain in the body of a patient for years without creating a great amount of disturbance Upon the state of the evidence, the court found that there was no hability proved against the surgeon. In ordering a reversal of the judgment of the trail court, it was said

"The eircumstances of this case are most unfortunate. Two little children have been deprived of a mother, a husband has lost his wife. A verdict charging that responsibility upon an experienced, careful, conscientious surgeon should be supported by evidence establishing the fact, or establishing facts from which it may be inferred to a reasonable certainty. It cannot and it ought not to rest upon evidence which leaves the fact in the field of doubt, uncertainty and speculation."

The justice of the ruling seems clear It was part of the plaintiff's case, before he could hold the surgeon, to establish that the negligence, if any, was committed during the 1920 operation and not during the earlier appendectomy. To permit the jury to speculate on such a point would result in a manifest injustice to the doctor.

On the point first considered, namely, the responsibility of a family physician for what transpires at an operation, the case has been followed as authority in a later case that deserves some In that case a general practitioner adcomment vised the extraction of certain teeth and recommended a certain dental surgeon Arrangements were made for the doctor to act as anæsthetist. and the patient told him that she wanted him to, as she said, "see me through and watch out for my interests through the operation and when I went under the influence of the ether" In that case, in holding that the doctor thus present at the extraction was not responsible for the malpractice of the operator, it was said by the appellate court

"The mere recommendation by one doctor of another does not make the one liable for the malpractice of the other This has been held true where one physician advises an operation, and, with the consent of the patient, arranges for it to be performed by another, a competent surgeon whom he assists And where the physician in charge of a patient calls a surgeon into the case to operate and assists in the operating by doing what he is directed by the surgeon to do, it has been held that he is not hable for negligence in the operation, in the absence of negligence in recommending the surgeon or on his own part in assisting him * * *

"It is well settled that, generally speaking, a physician who merely administers an anæsthetic to a patient who is operated on by another is not liable for the negligence of the operating surgeon"

DISTRICT BRANCH MEETINGS

The schedule for the annual meetings of the District Branches this autumn is now completed. The chronological order of their occurrence follows:

September 5-Third-Mountain House, Catskill.

September 19-20—Fourth—Malone. September 21—Seventh—Rochester. September 28—Fifth—Oswego. October 5—Eighth—Niagara Falls.

October 11—First—Grasslands Hospital, Val-

October 18-Sixth-Norwich.

November 16—Second. Not yet decided.

The proposed programs, as outlined at the executive conferences which have recently been completed, are the most promising that have been made in years. As these programs develop, their details will appear in the Journal.

Joseph S. Lawrence, Executive Officer.

ONTARIO COUNTY

The April Bulletin of the Ontario County Medical Society contains the following information regarding the second quarterly meeting of the Society.

The meeting was held on April 11, at the Clifton Springs Sanitarium, with president H. M. Smith in the chair, and forty members and five

guests present.

Dr. Ĉ. W. Grove of Geneva, Chairman of the County Committee to study the report of the Committee on the cost of medical care, gave a report of which the following is an abstract.

"The committee has endeavored to obtain a cross section opinion of the membership of the

allied professions, and of the lay public.

"Our inquiry has found very little, if any,

interest on the part of the lay public.

"It appears as the cross section opinion of the medical and allied personnel, that the practice of medicine and allied callings should remain in complete control of the professions interested.

"If at any time any type of sick insurance should appear, such insurance must be controlled, directed and managed by the professions interested and should never be permitted to be in any manner directed, controlled, or managed by lay or political organizations or persons.

or political organizations or persons.

"It is felt that medical care, in its entirety, is more than a commodity service and that it is never a machine type of service, but that it is a

service entirely peculiar to itself, which allied medical lines must provide without interference or hindrance for the benefit of the sick and suffering.

"Department store types of medical services will ever be unsuccessful and impossible as each patient and each potential patient will ever be a law unto himself. It would be unjust and unfair that the individual be denied the right to choose his own physician.

"With a metered medical service it is well known that a decided minimum service is delivered with the attendant loss of morale and mutual respects. It would appear that the plan does not fit into the life of this country.

"Experience, of late, well demonstrates that the public is manifesting decided signs of being most wary of accepting further that their private and intimate affairs be paternally directed and controlled by governmental or semi-political agencies.

"It is suggested that lessening or limiting the elaborate flattery and attendant expense that has developed in some and in too many hospitalizations and sick room care would materially lessen the costs of medical care. Needed and well chosen laboratory aids only should be used.

It was moved by Dr. Grove that the society express its appreciation of the work of Dr. Eise-

line, its secretary for the past 36 years, and furthermore, that the society remit his dues henceforth. The motion was carried by unanimous vote.

After a social dinner the following program

was presented:

1. Diseases of the Thyroid, Dr. Adrian S.

2. The Surgical Treatment of Prostatic Hypertrophy, Dr. W. C. Eikner,

3. Hormone Tests for Pregnancy, Dr. W. S. Thomas.

SUFFOLK COUNTY

The regular quarterly meeting of the Suffolk County Medical Society was held in the Irving House, Southampton, April 27, 1933, with 63 members present, and the President, Dr. L. C. Garbin, presiding. Dr. A. C. Martin. President of the Nassau County Medical Society, was present as a guest.

The following new members were elected:

Dr. Bertram Gottlieb, Huntington

Dr. Henry Greenberg, Lindenhurst

Dr. Olive Wheaton, Huntington

Dr. Donald Carmichael, Kings Park

The principal business of the day was the consideration of the Economic Committee, Dr. W. H. Ross, Chairman. The following recommendations of the Committee were adopted:

1. That the Economic Committee be given authority to effect agreements with the Com-missioner of Public Welfare and with the five public hospitals, making whatever compromise is necessary, subject to the approval of the Comitia Minora.

2. That the Economic Committee be increased to five members, one for each of the public hospital districts-Southside, Huntington, Mather, Southampton, and Eastern District—and given power to increase its number by one or more in each hospital district to act as sub-committees.

3. That the Economic Committee be given power to arrange with the Commissioner of Public Welfare a modification of the fee list

adopted in 1931.

4. That the Economic Committee be given authority to make decisions in all matters of disagreement regarding the medical administration of public welfare submitted to it by the Public Welfare Commissioner; and, that when no regulations exist as a guide that it can be instructed to apply the rule of common

5. The question has often been asked, "Shall

the specialist accepting cases under the same kind of authorization as that given to other physicians be entitled to charge the fee of a specialist or a consultant for his ealls or shall he charge the fees of the family physician?" The Committee offers the following recommendation:

That the specialist accepting cases which eome to him directly shall charge the fec of the general practitioner; and the fee of the specialist or consultant for only those calls, consultations or operations which are referred to him by the general practitioner because of his superior skill, providing that authorization is obtained from the Welfare Commissioner

for each consultation or operation.

6. The Committee has studied the plan of compensation arbitration as now in operation by the New York County Medical Society. It has considered the results in six hundred Most of the controversies between physicians and the carriers have been satisfactorily disposed of by the arbitration method. One member of the committee acted in one case as a member of the arbitration board recently in New York.

As a result of the Committee's experience and study it recommends to the County Society that a Committee of Arbitration be established, consisting of one representative of the County Society and one that the insurance carriers association be invited to appoint, under the chairmanship of the President or other member if the Society so chooses for the purpose of giving this method a trial regarding payments for services, "lifting" of cases, and other differences of opinion.

The Scientific Program was as follows:

 Obstetrics, by Dr. Royal C. Van Etten. New York.

2. Office Treatment of Orthopedic Cases, by Dr. D. E. McKenna, Brooklyn. E. P. KOLB, Sccretary.

DELAWARE COUNTY

The mid-year meeting of the Delaware County Medical Society was held in the parlors of the Presbyterian Church at Downsville, with Dr. R. Davidson of Hancock in the chair and twenty physicians present. The program began with a banquet served by the ladies of the church.

The guest speaker was Dr. Louis C Kress of Buffalo, Assistant Director, Division of Cancer Control of the State Department of Health, whose subject was "Five-Year Cures in Cancer," illustrated with lantern slides.

W. M. THOMSON, Secretary

DUTCHESS-PUTNAM COUNTY

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday, June 7, 1933, at the Harlem Valley State Hospital, Wingdale, N. Y., with 51 members present. There was a golf tournament in the afternoon and a ball game at 6.30 p.m. Dinner was served at eight o'clock, after which the meeting was called to order by the President, Dr. S. E. Appel at nine o'clock.

Dr. J. T. Harrington presented the following report of the Economic Committee concerning the formation of an arbitration board. It was voted that the recommendation of the

committee be accepted.

"The Economics Committee of the Dutchess-Putnam Medical Society makes the following report with regard to the formation of an Arbitration Committee for disputes between the insurance companies and the doctors about compensation cases.

"Two of the members of your committee attended a meeting of the New York County Arbitration Committee in New York on the 25th of May and had an extended discussion with Dr. Morris Rosenthal, the chairman of

the committee.

"At the meeting of the Economics Committee held on June 5th, it was decided to report to the Society (1) that the Economics Committee favors the formation of an arbi-

tration board in this area, (2) the committee feels that the Dutchess-Putnam Medical Society is perhaps not large enough and the amount of work which would naturally come before the arbitration committee in these two counties is not sufficient to warrant the formation of a committee in the Dutchess-Putnam Medical Society, so that it suggests (3) that the Medical Societies of the Counties of Ulster, Orange and Columbia be communicated with, with the idea that an arbitration committee may be formed in all of this area. Further, your committee suggests that the Medical Society of the State of New York be advised that it is the sense of the Dutchess-Putnam Medical Society that the matter of arbitration in the settlement of disputes between insurance carriers and doctors is a matter of sufficient importance to be taken up by the State Society with a view toward districting the entire state into areas where arbitration boards may perform satisfactorily."

There was considerable discussion on the subject of insurance for hospital care, and a motion was made endorsing the general plan of hospital insurance. The consensus of opinion was that the project was too new to be judged fairly at this time.

H. P. CARPENTER, Secretary.

FRANKLIN COUNTY

The regular semi-annual meeting of the Medical Society of the County of Franklin was held in Saranac Lake June 9, 1933, with the President, Dr. J. W. Kissane, in the chairand twenty members present.

The following nominations for officers for 1934 were submitted and unanimously ap-

proved:

For President: Dr. G. C. de Grandpre.

For Vice President: Dr. R. G. Perkins.

For Secretary-Treasurer: Dr. G. F. Zimmerman.

For Censor: Dr. W. W. Woodruff.

Dr. William Spencer Schwartz was elected to membership.

The fee bill for the treatment of County and town cases was discussed at length, and

the following resolution was adopted:

Resolved, that the doctors of Franklin County Medical Society adhere to the fee schedule of July 1, 1931, except that a reduction of twenty-five per cent be accepted in each item during the period of the present depression.

Dr. C. H. Van Dyke, of Malone, discussed

the Venereal Clinics held in Malone, and notified the meeting that the Board of Supervisors was unwilling to appropriate the money necessary for their continuance. The sentiment of those who discussed the clinics was that they were in an experimental stage and should be continued in Malone in order to determine their need and value.

Dr. C. C. Trembley of Saranac Lake, delegate to the New York State meeting, gave an oral report of the principal transactions of the

State Society,

The following scientific session papers were read:

- 1. "Some Aspects of Ovarian Dysfunction," by Dr. J. R. Goodall, Montreal, Canada. This was a learned paper showing some pioneer work in Endocrinology and predicting results that can be expected from its further development.
- 2. "Lumbar and Sacral Pain," by Dr. Edward K. Cravener, Schenectady, illustrated with moving pictures.

G. F. Zimmerman, Secretary.

THE DAILY PRESS

FOURTH OF JULY FATALITIES

The Metropolitan dailies of July fifth and sixth, have followed their usual custom of reporting the number of deaths which may be attributed to Fourth of July celebrations. The New York Times of July 5 says that only four deaths due to fireworks occurred in the United States, while the New York Sun said seven.

The Sun gave 185 as the number of lives lost in the entire country by accidents of all kinds, the figures for previous years being—

Year	Deaths
1928	205
1929	159
1930	178
1931	483
1932	243
1933	185

The deaths from important causes on Fourth of July, 1933, as given by the Associated Press, quoted in the New York Sun, were:

Automobiles	82
Drownings	.58
Drownings Other accidents	38

Commenting on the Fourth of July fatalities

the New York Herald Tribune of July 6, says:-

"There were enough firecrackers in town on Tuesday to preserve a vestige of the "old-fashioned" Fourth, enough explosives to send 670 persons to hospitals to be treated for burns. Luckily, none of the accidents was fatal. Compared with the old excesses of celebration, the holiday in New York and elsewhere could fairly be called safe and sane. Early reports noted only seven deaths from fireworks in the whole country. Thirty years or so ago they were numbered by the hundred.

The campaign for moderation undoubtedly has saved many lives—a clear gain to offset the loss, which not a few oldtimers still regret, of the robust spirit of the traditional Fourth. How well the reform has succeeded may be inferred from the 1933 compilation of 'Accident Facts' by the National Safety Council. In sixty-two pages of statistics there is no specific mention of Fourth of July accidents; apparently they are absorbed as minor details under other headings. The leading agent of destruction on the Fourth is no longer fireworks of any sort. It is the automobile, which presents a problem of safety and sanity, as yet unsolved, for every day in the year."

FREE DISPENSARY SERVICE

The free medical service given by dispensaries and the outpatient departments of hospitals has increased enormously during the last few years, as compared with the visits made during the prosperous years before the financial slimp of 1929. The New York Times of July 5 comments on the reports as follows:

'Use of out-patient clinics and dispensaries has increased in the last six years by nearly one-third in voluntary and municipal hospitals of the city and has more than doubled in the city hospitals, the United Hospital Fund reported yesterday. These figures were based on a study just completed by the Hospital Information and Service Bureau of the fund.

"The study showed that 1,500,000 patients now make more than 6,680,000 visits to the clinics and dispensaries annually, and that the hospitals spend about 14 per cent of their ex-

penditures on out-patients services and 86 per cent on patients in the institutions proper. A special study in forty-eight of the fund hospitals which had 3,700,000 visits last year, showed a deficit of \$1,283,621 in the elinic services.

"In 1927 there were 4,183,933 dispensary visits to all the hospitals of the city. The figure rose every year, passing the 6,000,000 mark in 1931 and reaching 6,688,215 last year. In the fifty-six voluntary hospitals comprising the United Hospital Fund the figures rose from 2,821,939 to 4,017,750 last year. In municipal hospitals the increase was from 842,391 in 1927 to 2,035,372 in 1932.

"The special study of forty-eight institutions with comparable figures for out-patient departments showed one-third of the visits to be entirely free."

ULTRA-VIOLET COLOR PERCEPTION IN BEES

Man's senses are his conscious responses to influences acting on his nervous system. His eyes respond to light whose wave lengths range between the red and the violet. There would not seem to be any inherent reason to prevent the development of eyes which would respond to the ultra violet rays, and the infrared, as certain bees seem to have done. The New York Times of July 3 carries a news item describing the experiments of Dr. Frank E. Lutz of the American Museum of Natural History, New York City, showing the actual response of certain kinds of bees to colors invisible to human eyes. The Times describes the experiments of Dr. Lutz as follows:

"Dr. Lutz made his experiments with the 'stingless bee' (trigona cressoni paratigma), a tropical species distinct from the common honey-bee but with similar visual apparatus. A bee's eye, it may be noted, is radically different from a human being's eye. It has no rods and cones and is far simpler in its elements.

"Dr. Lutz found a colony of these bees nest-

ing in a wall of the laboratory of the Institute for Research in Tropical America, which is on the island. A small hole in the outside wall was the bees' entrance. Dr. Lutz prepared cards on which were painted patterns in black and white, some in ultra-violet white and some a white that does not reflect ultra-violet light. Each card was pierced with a hole the size of the opening to the bees' nest. By placing a card with a certain pattern over the entrance to the nest Dr. Lutz established an association in the bees' 'minds' between that pattern and the entrance. When the patterns were shifted and the pattern that had marked the hole was placed nearby and another pattern placed at the entrance, most of the bees tried to get in through the pattern that had covered the hole and ignored the new pattern. The fact that a few of the bees did not fly to the old pattern was accounted for by the fact that new bees were hatching out while the experiment was in progress and they, of course, did not know the pattern."

BALDNESS

Baldness is the joke of humorists and the despair of scientists, but is of alluring interest to historians and statistitians as is shown in the following editorial from the New York Herald Tribune of July 3.

"In its annual conclave at Chicago the American Association for the Advancement of Science has found time from the discussion of more esoteric matters to consider the relation between the state of one's hair and that of his bank balance. One of the delegates announced that there seems to exist a close connection between income and capillary growth, evidently due to the influence of nervous anxiety on the roots of the hair. According to the new hypothesis of the scientists, a happy age is apparently a hirsute age, and a harried generation is a hairless one.

"Hitherto we have looked on baldness as a purely physical affair without mental affiliations. True, we have noticed that the Indians were never troubled with baldness, though once given to inflicting it on those whites who fell into their hands. If the locks of every Indian from Rowhatan to Sitting Bull seemed as shaggy as a buffalo's head, we ascribed it to

their outdoor life rather than to their lack of cerebration and worry. If the brunette peoples about the Mediterranean seemed less given to falling hair than the blond Nordics, we laid it to the sun.

"If we lift the hats of representative figures in history, we find little basis for generalizing. Socrates and Cicero, Shakespeare and Voltaire, Bismarck and Lenin were bald, though some of them found compensation in a beard. The fact that Caesar was bald and in debt for 25,-000,000 sesterces when he joined the triumvirate was probably a case of cause and effect. Evidence in the bewigged eighteenth century is difficult to gather, but when pates issued again with the French Revolution we find the heads of Benjamin Franklin and John Quincy Adams gleaming in all their republican nudity. In our own time both Mussolini and Mayor O'Brien have shining domes. On the other hand, among the well crested have been Pericles and Plato, Mirabeau and Andrew Jackson, the lion-maned Goethe and Beethoven, and Dumas and Ibsen. So are Trotzky and Hitler. Herriot and MacDonald, however their coiffures may differ."

BOOK REVIEWS

DISEASES OF THE LYE B, HOFRAT LRYST FUCHS, M D
The 15th German Edition of the Lehrbuch der Augenheilkunde as Revised by Maximilian Salzmann
English Edition authorized translation by E V L
Brown, M D Ociano of 641 pages, illustrated delphia, J B Lippineott Company, [c. 1933] Cloth, \$\frac{9}{7}\$ 00

The tenth English edition of Fuchs is ready and reminds us all of the passing of the master and his trans lator The German edition is in the capable hands of Silzmann and Dr E V L. Brown succeeds the lamented Duane. The names on the title page and prefaces are not the only new features of the book. The book is now Fuchs Diseases of the Eye and there are about 600 pages of printed matter. This is a reduction of some 500 pages obtained by eliminating chapters on operations, diagnostic methods and eye museles. Some will like this and some will not but there are conditions now operating that even the publishers must consider velcome addition to the book is a group of 40 colored plates from paintings by Prof Salzmann showing typical and important fundus conditions. It will be difficult to find anywhere equally good material of this kind The book has not a superfluous word in it but on the contrary, there is no lack of clarity or attention to im portant detail. There is but one criticism that can be made and that relates to the slit-lamp as a diagnostic It would seem that more attention should apparatus be given to the role this instrument has assumed in diag nosis We predict that Dr Brown will supplement this fine work with the necessary detail of this phase of diagnosis just as Dr Durne filled out the space allotted to eye muscles

RALPH I LLOYD

OFFICE SURGERY BY FERWICK BEERMAN, M D Octavo of 402 pages illustrated Philadelphia, J B Lippin cott Company [c 1932] Fabrikoid, \$500 (Every day Practice Series)

One rarely reads books so admirably corresponding to their titles and intended purpose as the one under review. Three hundred and eighty six pages of sound information and advice put into succinet and economically worded phrases. The author discusses, in a systematic manner, office anesthesia wounds mijuries, fractures, tumors and surgical diseases suitable for office treatment. Wherever hospitalization is preferable to ambulatory treatment this is stressed. Office Surgery' is the volume of choice in the opinion of the reviewer for the desk of the general practitioner and the young surgeon.

George Werd

THE DIFFERENTIAL DIAGNOSIS OF ENDOCRINE DISORDERS BY ALLAN WINTER ROWE, M D Octave of 220 pages Baltimore The Williams & Wilkins Company, 1932 Cloth \$400

This monograph is a detailed report of twenty years of study of over 5000 subjects who were investigated by the following method. A complete medical history, physical examination special examination and the performance of an eliborate series of routine laboratory tests.

The glandular disorders discussed are those of the putu itary, thyroid gonads and adrenals The results of the examinations are grouped under clinical and laboratory findings and form a valuable addition to our present knowledge on the subject

In view of the prominence which has recently been

accorded to laboratory tests as bases of endocrine diagnosis, it is interesting to note the author's limitations on the interpretation of these tests

the interpretation of these tests

1 No single test can be regarded as significant unless it be checked and controlled by a number of other inde

pendent observations

'2 No single findings suggestive of an endocrine discase should be adduced to support such a diagnosis until all possible non endocrine causes have been ruled out

"3 Careful clinical observation is as important as are laboratory tests. The latter furnish a basis of tested facts for the interpretation of the subjective evidence of the former."

This book is of value to every student of endocrinology and is especially recommended to those who desire to become better acquainted with the present accepted methods of endocrine investigation which in a large measure are based upon the pioneer efforts of Rowe and his co workers in the laboratory Murray B Gordon

The Sex Technique in Marriage. By Isabel Eastle Hutton, MD 12mo of 160 pages. New York, Emerson Books, Inc., [e 1932] Cloth, \$2.00

Here is a small volume of practical value that is easy to read and simple in its presentation of a subject usually considered difficult and often made complicated. It is medically sound and the physician will find it not only safe to recommend to his clientele but worth while read ing himself.

Possibilities and Need for Development of Lecal Medicine in the United States Prepared by Oscar T Schultz, M D Octavo of 135 pages Washington D C Published by the National Research Council of the National Academy of Sciences 1932 Paper, \$150 (Bulletin of the National Research Council, No 87)

This work fully covers the field of the different methods of investigation of the problems of eriminal legal-medicine in the different states of the United States, England and Scotland, and clearly exposes the faults in the different methods by which such problems are handled

His plea for the establishment of fully equipped institutes connected with universities and manned by competent workers for the investigation of such problems as
is done in certain European countries is ideal, but as
he suggests the appointments of the investigators in such
institutes must be free from political influence Whether
it is possible to after our fundamental principles of criminal jurisprudence and prevent the taint of influence, is
a grave question.

ARTHUS C BRUSH

Neue Genanken uber das Blur-und Mieren-Problem By Kurr Bergel. Octavo of 22 pages illus trated Berlin Deutsches Verlagshaus Bong & Com pany [c 1933] Paper, 3 Marks (Irrtumer der Medizin 1)

This monograph embodies certain new ideas relating to the pathogenesis of disease. The author considers the blood from the standpoint of a regulator of pressure, and not as a nutritive agent disease as a disturb ance of pressure the true significance of blood pressure, the mechanics of the kidney, renal disease from the intestine and certain other interesting conceptions. The reading of this pamphlet is a rather novel experience

HOSPITAL INSURANCE IN WEST VIRGINIA

The leading article in the June number of the West Virginia Medical Journal is the President's Annual Address by Dr. D. A. MacGregor of Wheeling, in which hospital care on a prepayment or insurance basis is discussed as follows:

"This is a most interesting and valuable experiment. The two major plans of this character in existence in our State are operated on a high ethical plane. In both instances all hospitals in the community served belong to the organization. In both instances there is no attempt to combine pre-payment for hospital care with pre-payment for medical care. In both of the communities served there have been large list hospital contracts, for both hospital and medical care, for many years. It is to be hoped that with the spread of this new idea for hospital service there will be developed a stronger sentiment against the whole list hospital practice with its numerous abuses. I am advised that the hospitals in this city of Charleston have already agreed among themselves to abandon their list practice in and near the city.'

Dr. MacGregor in a letter explaining "List" hospitals, says:

"In the southern half of West Virginia, where we have a large number of coal mines in small communities, there has been a system of list hospital practice for many years. The employer takes a check-off from each employee's wages of from one to two and a half dollars per month. Contracts are made with privately owned hospitals and their staffs, whereby medical, surgical, and hospital service is given to the employees and to their families in cases deemed suitable for hospital attention. The hospital may be from three to thirty miles from the industry. A physician is usually employed at the industry to take care of minor illnesses and accidents. He receives a part of the check-off.

"One of the outstanding objections to the scheme is that the employee pays for the care of his industrial accident through the check-off; and the employer is relieved of this obligation, which should be placed on the employer by the State compensation department. Of course, there are many other disadvantages and abuses. It is to the interest of the owners of the private hospitals to get the patients out just as soon as they can. Furthermore, the right of choice of physician and hospital is denied to the employee, unless he chooses to pay his way elsewhere."

Dr. MacGregor described contract practice in West Virginia in an excellent paper which he gave before the annual conference of the Secretaries and Editors of the State Societies held last November under the auspices of the American Medical Association. This paper is published in the December number of the A. M. A. Bulletin.

HEALTH INSURANCE IN WASHINGTON STATE

The June number of *Northwest Medicine* contains the following bulletin issued by the Committee of Seven of the Washington State Medical Association on the subject of health insurance:

"The Committee of Seven of the Washington State Medical Association is conscious of the anxiety and perplexity that prevails in the medical profession relative to health insurance, and issues this bulletin for the double purpose of recording the trend of thinking that has prevailed in the Committee and soliciting comments by members.

"Insurance companies are active in their struggle for profit from health insurance business, some industrial contract practice groups are muddying the waters by extending their practice to family insurance, new groups of physicians are talking about organizing for health insurance practice, and British Columbia is forwarding its plans for compulsory state health insurance. Nobody seems to know just what is going on, fear has entered the picture and there is some danger that the health insurance bogie may cause the profession to act unwisely through sheer panic.

"The Committee recognizes a social movement toward health insurance and believes that a negative position should not be taken by the medical profession, but does not yet find a sufficient crystallization of opinion among physicians regarding the extent of the economic necessity for health insurance to justify the recommendation of any plan of action. Unquestionably there is a certain percentage of our population that must have free medical care; there is another percentage that cannot afford to buy full medical care on the strict business basis of paying production cost plus a reasonable profit; and there is a third large percentage that seeks some plan for getting full medical care for little or no cost.

*Monosaccharida ** Disac	chande ***1	

Maltore splits into two molecules of dextrose. Sucrose and lactose split into one molecule of dextrose, and one of levulose or galactose respectively. It is no doubt due to the simpler structure of maltose that it is more readily absorbed than other sugars. It must also be considered that after assimilation the levulose of sucrose and the galactose of lactose must undergo conversion into dextrose, which is the only form in which sugar is present in the blood. It is reasonable to suppose that this conversion requires an expenditure of metabolic energy not required when carbohydrate is absorbed entirely in the form of dextrose.

RATE OF SUGAR ABSORPTION IN NEWBORN

MALTOSE OR LACTOSE IN INFANT FEEDING'

Answer—The superiority of one form of carbohydrate over another in artificial feeding of infants has been much discussed during recent years. It is generally accepted that one is mile.

amount it is necessary to add carbohydrates in some form Admitting that lactose is the super symphoth in human milk, it does not follow that it is the hugar best tolerated in another medium, such as cow's fulk it is generally believed that lactose is more likative, thin sucrose—that it must be fed with a certain another of caution, as fermentative upsets are likely to follow it, amounts approximating that found in human milk are fed There is cause for disagreement among climicans, as it is important to consider the other food elements, i.e., the amounts of fat and protein fed as well as the medium in which they are fed For example, when lactic each milk is used, more added carbohydrate seems to be tolerated than when sweet milk mixtures are fed Sucrose has the advantage of being much cheaper and is always available Evidence has not been presented that it should

not be used in infant feeding. With its general use in large infant welfare clinics where supervisions a matter of routine, there is less to be said against it as far as elm scal results are concerned. The complaint that it is too sweet is not often encountered when the usual amounts are fed. The dextrin malitose preparations possess certain advantages. When they are added to cow's milk

destrons the maltose and then to destrose, fermentative and ressessant less likely to develop. Those preparations confaming relatively more maltose are more lexative than those containing a higher percentage of destring unless alkali salts such as potassium salts are added). It is common experience clinically that larger amounts of destrin maltose preparations may be fed as compared with the simple sugars. Obviously, when there is a lessened sugar tolerance such as occurs in many diges tive disturbances, destrin-maltose compounds may be used to advantage. *Squeries and Minor Notes, J. A. M. A. 88 266

definite and measured

ABSORPTION

CURITY suture absorption is measured and controlled—and proved before you use it by a final and exclusive double check.

The Curity Laboratories have devised a chemical digestion test by which it is possible in twenty-four hours to predict the behavior of catgut in hody tissues (for any period of time). The solutions used are composed of many of the same body enzymes that act on the suture. The digestive action of these complex solutions has been very definitely standardized against body absorption and their accuracy proven.

Curity Sutures are then put through an actual digestion test by the customary method, where the digestion takes place and is observed under actual body conditions. The sutures action in this test must measure up to the standard indicated in the chemical digestion tests before absorption is finally approved.

Samples for clinical trial sent on request.

A product of Merckens-Buffalo, N. Y.

(Continued from page 902-adv. xii)

"Recently two well-dressed men, driving a fine, new car, stopped at a near-by house. One of the men went in, introduced himself as Dr. Mayberry, a Vicksburg oculist, and asked if anyone was m need of his services. The elderly housewife ad mitted that her eyes were none too good, and submitted to examination, when it was discovered that there was an unusual condition in one of the eyes, the nature of which was unknown to Dr Mayberry. However, most fortunately, the other man in the car was a celebrated Kansas City surgeon, Dr. W. I. Handlow, and at Dr. Mayberry's suggestion, he was invited to examine the eye.

"What might have been expected, happened Dr. Handlow, who, among other things showed the ring of a thirty-second degree Mason as prov of his integrity, diagnosed a "cancerette" behind the eyeball. He had seen a similar case two days before in Vicksburg, for treating which he had been paid \$1,700.00. There are only four place in the United States where these are properly handled: in Atlanta, in Washington, at the May Clinic and—of course—in Kansas City. Else where such conditions call for enucleation of the eye, but at these four places radium is used Luckily Dr. Handlow had a \$5,000 bottle of radium in his pocket, and as the poor old lady was in immediate danger of total paralysis unless the "cancerette" were removed, he was per suaded to take it out, charging only for the radiun used. This he proceeded to do by putting four drops of the radium into the eye at minute intervals. Usually one or two drops are enough, but this was an extremely tough case. Finally he picked the "cancerette" out with a pair of forceps, showed it to the old lady's husband—whose eyes are none too good, explained that it was deadly poison and would kill anything that ate it, and consigned it to the flames. The old lady doesn't see any better than before, but she is rid of the deadly "cancerette" at a cost of only \$380.00, the price of the four drops of radium But the bank holiday proved a sad thing for the eminent Kansas City practitioner, for the husband got his second sight next day and stopped pay ment on the check."

MEDICAL LIEN LAW FOR ARKANSAS

The April number of the Journal of the Arkansas Medical Society contains the following description of the medical lien law that was recently passed by the Legislature of the State:

"To enable physicians, nurses, and hospital to obtain on their own initiative security fo

the payment of bills due from patients treated because of injuries suffered through the fault of some other person, the recent Arkansas Legislature enacted into law through which a physician, nurse or hospital who renders service to such a patient can establish a hen for the value of the services rendered on any claim the patient may have against the person by whom he has been injured. This law was known as Senate Bill 361, introduced by Senator Lawrence E. Mitchell of Prescott, supported by our legal advisor, Hon Peter Deisch, and the committee on Medical Legislation, headed by Dr Val Parmley.

"The bill has been signed by Governor Futtell and is now known as Act 130.

"The title of the new law is as follows:

"A Bill for An Act To Be Entitled: An Act Concerning Liens for Money Due Physicians, Dentists, Nurses, and Hospitals, for Services Rendered for the Relief and Cure of Injuries Caused by the Fault or Neglect of Other Persons, on Claims and Rights of Actions Accruing to Such Injured Persons by Reason of Such Injuries"

The text of the law fills four pages of the Journal.

COPPERIN

in the new, economical 100—capsule package

COPPERIN "A" for adults, "B" for children, in the new 100-capsule package provides your patient with more than a month's supply at a cost of only 50 cents per week.

Copperin has been shown by clinical use in a large number of cases to be a most desirable type of iron therapy in anemias of pregnancy, post-operative anemias, and anemias of children.

Write for the literature and samples if you wish.

MYRON L. WALKER CO., Inc. 508 Franklin Avenue, Mount Vernon, N. Y.

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, I inscrtion, \$1.50; three cents each for additional words.

1496 Carroll Street, Brooklyn, N. Y., for rent or sale, 11 room one family hrick modern house, Crown Heights section, 3 haths, large rooms, grounds, dignified outlook, perfect condition, reasonable rent. Address Box 15, Care N. Y. State Journal of Medicine.

PRACTICE FOR SALE

Richmond Hill, L. I., N. Y., Home and Practice, 10 room house, double garage, reasonable. Have made money. Will show books. Collections for the past 12 years 100%. Reason for wanting to sell is Specializing. N. Feld, M.D., 104-16 108th St., Richmond Hill, L. I., N. Y.

To let, Unfurnished, 5-room apartment in 2-family house. All improvements. Suitable for doctor. Rent reasonable. 'Phone RAvenswood 8-4947. Address: 30-76 43rd Street Astoria, L. I. City.

Retired Physician offers his beautiful modern home for sale. Well located to command practice. Valuation \$35,000. Price \$25,000. Easy terms. Fruits and flowers. One block from Ocean. P. O. Box 73, Allenhurst, N. J.

LOCUM TENANS WANTED

Young physician, Graduate of Grade A School, one year general rotating internship in large City Hospital, and one year each as Resident in Medicine and Neurology in accredited institutions, licensed in N. Y. State, highly recommended, desires Locum Tenans for any period. Available August First. Address Box 20, Care N. Y. State Journal of Medicine.

"CONGESTIVE HEART FAILURE"

Before the Cincinnati Heart Council, Dr. B. A. Schwartz reported on a series of 37 cases of congestive heart failure treated with digitalis and Metrazol (*Ohio State Med. Jr.*, May, 1933, pp. 308-310).

The author made use of the circulatory stimulant Metrazol in place of, or in conjunction with, digitalis in a selected group of 37 cases of chronic congestive heart failure in which digitalis did not prove effective or where the patient's gastro-intestinal or even nervous system was partially or wholly intolerant to this drug.

The VEIL Maternity Hospital WEST CHESTER, PENNA.

For Care and Protection of the BETTER CLASS UNFOR-TUNATE YOUNG WOMEN

Strictly Private. Absolutely Ethical. Patients accepted at any time during gestation. Open to Regular Practitioners. Early entrance advisable.

Adoption of babies when arranged for. Rates reasonable. Located on the Interurban and Penna. R. R. and the Lincoln Highway. Twenty miles southwest of Philadelphia.

Write for booklet

THE VEIL

WEST CHESTER, PENNA.

Case histories are given and many references made to reports from cardiologists and a comprehensive bibliography is included.

In conclusion Dr. Schwartz writes:
"Our clinical experience with digitalis and Metrazol in this group of cardiac patients with congestive failure, leads us to conclude that there is a definite synergistic relation between the two stimulants. In those cases where normal doses of digitalis had been found to be toxic or ineffective, smaller doses of this drug in conjunction with Metrazol often proved of value in obtaining the desired results. Where digitalis is not tolerated at all, Metrazol alone has

been used with success. In cases of acute digitalis poisoning Metrazol has proved of definite value. In acute cardiovascular collapse the use of Metrazol is especially beneficial."

Information and a trial quantity of this circulatory and respiratory summant, Metrazol (Council Accepted) may be obtained, upon request to the markacturers, Bilhuber-Knoll Corp., & Ogden Ave., Jersey City, N. J.—Adz.

VICHY CELESTINES

The Medical Profession will be interested to know that the Vichy Company of Paris has given special consideration to the needs of the individual physician, wherever located, in obtaining supplies of Vichy water for himself and his patients.

In order to facilitate the distribute in this country, the American Agency of French Vichy, Inc., 503 Fifth Avenue, New York, has been appointed Sole Agents for the United States.

The Vichy Company of Paris has expended large sums on improvements recently completed, at the bottling establishment at Vichy, whence the famed natural mineral water from Celestins Spring and also from the Grande-Grille and Hospital Springs is shipped to all parts of the globe-Adv.

THE TREATMENT OF WHOOP-ING COUGH WITH ELIXIR GOLD TRIBROMIDE (ELIXIR BROMAURATE)

Elixir Bromaurate is a strong neurosedative and antispasmodic. It inhibits the irritability of the coughing center and relieves the spasmodic attacks. After a few days treatment, the attacks become shorter and milder and the children sleep better. In two or three weeks the cough gradually ceases. Elixir Bromaurate is also most valuable in bronchial asthma, chorea, migraine and petit mal.—Adv.

of Diabetic Patients

Approximately 75% of Diabetic Patients may be successfully treated by properly regulated diet.

DIVERTICULOSIS OF THE ALIMENTARY AND URINARY TRACTS* By EDWIN BEER, M.D., NEW YORK, N.Y.

5 one surveys the literature of medicine, one cannot fail to be impressed with the need of the closest cooperation between its many sister sciences The study of pathological anatomy has led to many chinical advances, and, on the other hand, the observations in the clinic have stimulated pathological and chemical researches If one is optimistically inclined, one cannot fail to conclude that many of the pathological conditions that were not observed either in the clinic or in the autopsy room, really existed with about the same frequency as we observe them today, but owing to human oversight or error, they were not On the other hand, if one is more inclined to pessinusin, one might conclude that the human race is degenerating, and gradually succumbing to more and to newer pathological manifestations Perhaps there is some truth in both viewpoints Not so long ago ulcer of the duodenum was considered an unusual entity. whereas gastric ulcer was considered much more common Was this due to oversight and to human error in observation? Again, bladder tumors were considered a rare condition at the commencement of this century and now, since the clinician knows how to recognize them, their fre quency is quite appulling. Perhaps in no group of diseases is this apparent increase more strik ing than in the subject of tonight's presentation Prior to the commencement of this century, di verticula of the hollow viscera exclusive of the verticula such as Zenker's and Meckel's diverticula of the colon and of the urinary bladder were practically unknown in the clinic, and only rarely reported by the pathologist, even though the diverticulum associated with the name of Meekel had been described in 1671 by Morgagni Such diverticula nowadays are so well known to the average chincian, and naturally to the pathologist that it is with some hesitation that a review of this subject is presented tonight It is difficult to believe that these conditions are new entitiesthat they have increased in numbers so rapidly that now thousands of cases are on record. When I collected all published cases of diverticulltis2

of the sigmoid, etc., in 1904, there were only eighteen clinically observed cases recorded About ten years later when I made a similar reviews of the somewhat analogous conditions in the urinary bladder, there were only nineteen cases recorded in the clinical literature. In the intervening period, the hterature has been almost flooded with additional cases of both intestinal and bladder diverticula, and some clinics have reported series varying from over one hundred cases to over one thousand cases of these interesting conditions cases which have been carefully observed and often treated with great success. I cannot but feel that the optimistic attitude referred to above even though it carries with it a certain amount of cruicism of our predecessors, is justified and that the discrepancy between the incidence of the diserse today and thirty years ago is attributable to the human error factor. It is difficult to explain this discrepancy on the basis of increased incidence of these diseases though the prolongation of life and the great increase in the population may have influenced to some extent the marked increment Newer methods of investigation, new instruments of precision have made the recognition of these pathological conditions possible and the Roentgen ray, above all, has thrown a bright light into this whole field and established with great accuracy the frequency of these curious pathological entities

Diverticula have been observed in all parts of the almentary tract from the pharyne to the rectum is well as in the utmary tract from the urcteropelvic junction to the penile urethra both these systems many interesting and instructive analogies are observed and by a study of these diverticula in both systems a somewhat clearer insight as to their causation is obtained Considerable difference of opinion has been voiced as to the factors that lead to diverticula formation, some authors believing that all, or most are acquired, others that most are con genital, and others again combine the two view points From a study of the anatomy of the diverticula and the recognition of all the walls of the organ from which it is derived ie, mucosa submucosa, and muscularis, one can fairly con-

^{*} Read as the Muetter Lecture Lef re the College of Physicians I hild left in Decenter 2 1931

clude that such a diverticulum is of the congenital type, corresponding as it does in structure with Meckel's diverticulum and those found in fœtuses or in early life. Occasionally adjacent disease process may draw on one of the hollow viscera and produce by traction a diverticulum having these same anatomical characteristics and though it is evidently acquired, its structure may closely simulate the congenital type. other hand, many diverticula, in fact most of those that I have seen, have no such regularly disposed layers as the definitely congenital; they are composed of mucosa, more or less submucosa, and here and there smooth muscle bundles. Are these to be considered congenital diverticula in which atrophic changes have taken place as a result of the pressure changes and subsequent stretching of these pouches or are they all acquired? I believe many, especially in the urinary bladder, are to be interpreted in the former sense and others, perhaps the great majority in both the alimentary and the urinary tracts, in the latter sense.

The analogy between the small diverticula that develop as multiple herniations of the mucosa between the hypertrophied and separated muscle bundles in the bladder and those that occur in the colon, especially in the sigmoid, is most striking. They both occur in organs that act as reservoirs, in which pressure changes are frequent, whether urine, feces or gas, produce these changes. They develop usually in adult life in patients who have obstructive conditions in the urethra or in patients who have some intestinal disturbance, whether flatulence or constipation, associated with a possible hypertonicity of the anal sphincter. In both systems they are hernial protrusions of the mucosa with little or no evidence of muscle tissue in their walls. Whether the vascular structures that perforate the walls make for weakness where herniation occurs has not been proven, even though such vessels are often adjacent to the diverticula. Perhaps they lead the way after the weakness in the connective tissue or muscular tissue allow of the inception of the process. Congestive cardiac disease and portal obstruction do not seem to predispose to their development as would be expected if the weakness were primarily where the vessels perforated the involved hollow viscera. This type of diverticula formation has all the earmarks of an acquired process. The same process in the esophagus seems to produce the pulsion diverticula between the inferior constrictor muscle and the cricopharyngeus at the upper end of the esoph-Here the trauma of hasty deglutition (bolting of food) seems to force the weak point and gradually a pouch is acquired which presents the definite picture of a diverticulum.

Between the rather definitely congenital and acquired diverticula there is a large group of diverticula, particularly in the urinary bladder,

which are difficult to classify. The same applies to those diverticula in the stomach, duodenum and small intestine, as well as in the ureter and urethra, in which the pouch formation is not due to giving away of the wall due to inflammatory disease, as in ulcers or adjacent to ulcers. In the urinary bladders we find with some frequency single and multiple diverticula, which are usually much larger than the mucosal herniations referred to above which bear such similarity to the sigmoid diverticula, and many of these show but scanty evidence of smooth muscle tissue in their walls. They are at times seen in early life (I have excised several such diverticula in young children), but may occur or be found at all ages and are frequently associated with obstruction at the neck of the bladder, either contractures or prostatic enlargement. In the children that have had this condition, no evidence of obstruction was detected by me. These diverticula may grow to large size; one recently recorded held five litres of urine.4 It must be apparent that this group is totally different from the group previously described which resembles so closely the diverticula of the colon, and the question is still under discussion as to whether they owe their origin to a congenital fault or not. In view of the fact that they arise so regularly close to the normal ureter opening, in some rare cases the ureter empties into the pouch quite a distance from the lumen of the bladder, one cannot but feel that there is a congenital "anlage" for their development, whether in the form of an extra ureter "bud" or otherwise. The increase in size would gradually develop as a result of the pressure changes in the bladder and what may have been imperceptible at birth or only a dimple, gradually grows in size, so that it can be recognized in childhood or adult life as a sizeable diverticulum. A similar embryologic explanation has been offered for most of the diverticula of the small intestine, but here owing to less pressure changes the large pouches seen in the bladder do not develop.

All the above three types, the congenital, the acquired, and the congenital that have evolved acquired characteristics, are fairly considered true diverticula, as opposed to those false diverticula which result from traction from without, from disease in the organ involved, or from adjacent disease or trauma which perforate the organ that develops a diverticulum. Abscesses may extend into a hollow viscus and communicate with same, producing in this way an artificial pouch. Trauma, such as operative repairs of vesicovaginal fistulæ, may artificially produce a similar pouch with all the signs, symptoms, and possible complications that arise in any true diverticulum.

The most interesting diverticula, as well as those most frequently encountered in our clinical work, are: those occurring in the pharyngo-esophageal area; those occurring in the intestine, especially in the colon; and those occurring in the

urmary bladder In the stomach, small intestine (excluding Meckel's diverticulum), rectum, ureter and urethra the condition is apparently somewhat of a rarity, and this is probably not due to the human error factor, as for a number of years the possibility of their occurrence has been in the number of the clinician and adequate search has undoultedly been instituted

All diverticula, irrespective of the organ from which they arise, are prone to similar pathological changes in the course of their development Their growth is unusually slow and only in the esonhagus, duodenum, and biadder do they grow to any size Irrespective of their size, they are exposed to trauma and infection and both these conditions combined may lead to serious compli-Meckel's diverticulum occupies a pecuhar position in this whole group, as, owing to its varying anatomy and adhesions at times it leads to intestinal obstruction, acting as a band or even gets tied into most bizarre knots that lead to obstructive conditions and to gangrene peculiarity of this congenital diverticulum is the finding in its miscosa of typical bleeding peptie ulcers which are eaused by or derived from misplaced gastrie mucous membrane Other peeuharities of this diverticulum are its opening by a narrow or wide channel at the umbilicus other diverticula, except those rare bladder urachal pouches never empty primarily at the navel nor are liable to produce the above intesti-Foreign bodies are hable to nal complications get lodged in these pouches and may lead to perforation with localized or diffuse infection Even without the introduction of foreign bodies, inflammation and ulceration are hable to develop and these in turn lead to more or less extensive destruction of the various walls of the diverticula and to peri diverticulitis and adhesions to adjacent tissues and organs, without or with perforation into such organs In the colon or the bladder, long stagnation may lead to inspissation of the contents of the diverticula or the development of calcult and quite regularly one finds small hard fecal masses in the acquired diverticula of the colon, much less frequently stones in those developing in the urinary bladder result of the chronic irritative process, occasionally neoplisms develop in these pouches and both benign and milignant growths, carcinomata and more rarely sarcomata have been encountered

Undoubtedly the great majority of diverticula do not give clinical evidence of their existence and are recognized only in careful routine examinations. When inflammatory changes set in, they often begin to give symptoms and cause trouble Esophageal diverticula may give symptoms from pressure and Meckel's and duodenal diverticula may also produce symptoms by mechanical interference with the intestinal lumen or by pressure on adjucent ducts. All others become vocal when infection develops which may lead to local symptoms of the pressure of the context of th

toms or at times to reflex symptoms suggestive of gastro duodenal disease

DIVERTICULA OF THE STOMACH

According to recent study the earliest mention of such a diverticulum was by Helmont in Only a few hundred are recorded in the literature and most of them have been recognized during routine roentgenological studies of the stomach and intestines At operation they have been rarely encountered and at autopsy a few Most of the cases have have been recognized Apparently the true diverbeen found in adults ticula are more common at the cardia where they are composed of all the coats of the stomach and are possibly congenital. In the distal part of the stomach, diverticula resulting from ulceration are found, presenting the picture of false diverticula The frequency of the "Niche" formation in ulcer bases is well known and may be the starting point Symptomatof some of these acquired pouches really these diverticula, unless associated with other pathological changes, give rise to little dis-If associated with these changes, which may lead to perforation or abscess formation, surgical therapy may be necessary

Diverticula of the Duodenum, Jejunum and Ileum

These diverticula are more common than those in the stomach, and those in the duodenum have been recognized with increasing frequency since radiographie investigations are routine Case diagnosed eighty-five cases in this way a recent German publication, another series of fifty duodenal diverticula was recognized in this Diverticula in the rest of the small intestime are rarely visualized in this manner. In some diverticula an air bubble has been seen above the opaque barium 8 Faise diverticula also occur in the duodenum secondary to ulceration, and at times between the ulcer and pyloric ring anatomy of these latter pouches, has not been de seribed as far as I know Those occurring in ulcer bases or adjacent to these are similar to the same process in the bases of gastric ulcers cording to recent publications, about fifty cases of diverticula of jejunum and ileum (excluding Meckel's diverticulum) have been noted and the Roentgenographic diagnosis was reported as made in only three cases. This is evidently innecu rate, as a perusal of American literature shows of Whereas in the duodenum these diverticula are usually single, in the lower part of the small in testine they are usually multiple and in one recent case, over three hundred such pouches were re corded There is considerable difficulty in explaining those diverticula that do not develop from ulcer bases Some authors think misplaced panereatic tissue which is occasionally found in their walls suggests that developmental anomalies under he the process, especially below the duodenojejunal junction. Atavistic influences would thus underlie the development of these curious structures. Others believe there is a primary connective tissue weakness which predisposes to the mucosal herniation. In the various parts of the duodenum, diverticula develop more frequently near the entrance of the ducts than in parts one and three and often grow into the head of the pancreas. In the jejunum and ileum they seem to develop almost regularly between the leaves of the mesentery, differing in this way from Meckel's diverticulum, though some have been noted on the convexity of the bowel and pancreatic tissue, or neoplasms have been found in their walls.¹⁰

Symptomatically these diverticula are liable to be quiescent unless inflammatory changes take place in them or a foreign body is caught in them and leads to perforation with abscess formation or to perforation into the peritoneal cavity. duodenal diverticula, reflex gastric symptoms somewhat suggestive of gastroduodenal ulceration Occasionally obstructive are not uncommon. symptoms, with or without jaundice develop. In view of these varied symptoms, a fair number of duodenal diverticula have been operated upon, either by resection or by infolding. Whether any of these operated cases have subsequently recurred, the literature does not make clear, though early control pictures have given no indication of recurrences. In the ileum, similar resections of the pouches have been made, and in a few cases of multiple, extensive diverticulosis of jejunum or ileum, segments of bowel have been resected.

Meckel's Diverticulum

This congenital pouch occurs usually in the last part of the ileum within one yard of the ileocecal Though usually small, about the size of a plum, it may be thirty centimetres in length: Many of its peculiarities have been referred to in the beginning of this paper. Its frequency is much greater than those in other parts of the small intestine being found, according to the statistics of the British Anatomical Society, in two per cent of autopsies. Considering this incidence, it is surprising how rarely it gives rise to symptoms and how infrequently surgical reports of its removal are published. For many years in every so-called interval appendicectomy that I performed, I examined the lower ileum for such a diverticulum and never encountered one. On the other hand, in a similar series of five hundred seven cases, R. M. Harbin¹¹ has found Meckel's diverticulum in seven cases.

The many bizarre pathological pictures produced by this vestigial organ are fairly well known, even though no one has encountered all of them in his own experience. Derived as it is from the omphalemesenteric duct, it may remain open all the way to the navel and produce a mucous membrane sinus either connecting with the

ileum or ending as a blind pouch. tumors of various kinds may develop in the peripheral or proximal end and at times the prolapsing mucosa may present gastric mucosa. If the peripheral end is well closed, it occasionally is represented by a fibrous band which may lead to intestinal obstruction, as loops of gut become engaged under the band thus formed. Even if no such band exists, similar obstructions are caused by the diverticulum itself, especially if it is adherent or twists itself into knots of most surprising pattern. These peculiar gyrations may lead to strangulation and gangrene of the diverticulum itself; in other cases to strangulation and gangrene of other loops. At times it invaginates into the ileum and leads to extensive intussuscep-Repeatedly it has been encountered in tions. hernial sacs. Perforation by foreign bodies which get lodged in the diverticulum is no great rarity, and hemorrhage from ulceration usuany due to misplaced gastric mucosa is being more frequently recognized and reported. Perforation into the bladder is a rarity.

Fortunately the neck of these diverticula is usually wide and their muscular wall is able to keep them fairly empty so that inflammatory changes are uncommon. If their frequency at post mortem is as great as reported by the English Commission and others, it is surprising how rarely one is called upon to treat their intrinsic disease or conditions secondary to their presence.

The diagnosis of Meckel's diverticulum is at best a good guess, as no pathognomonic features are known. As far as I know, radiographic studies have given no conclusive data, which is surprising in view of their frequency.

At operation, ablation or invagination (in small diverticula) have been carried out. In the more complicated cases with other secondary pathology, further surgical measures must be taken as indicated by the findings.

DIVERTICULA OF THE APPENDIX

These diverticula¹³ are rather infrequent and almost always of the acquired type, resembling the mucosal herniations found in other parts of the colon. They are probably secondary to previous attacks of inflammation and naturally predispose to further trouble in this organ. Some of the pouches may lead to retention cysts and simulate mucoceles of the appendix and when they rupture into the free cavity may give rise to the rare entity known as pseudomyxoma of the peritoneum. They are accidental findings at operation or at autopsy and practically impossible to recognize by radiography.

Recently, in connection with a study of cecal diverticula, a review of these structures has been made and emphasis has been placed on the possibility of acquired diverticula developing in the base of an excised appendix.¹⁴ Apparently the

purse string closure of the eccum over the ligated appendix stump predisposes to this type of pouch formation, sometimes following suppuration about the ligated stump and other times even without such suppuration. By crushing the stump and ligating with plain cat gut, which is rapidly absorbed, the purse string suture method will probably but rarely lead to such artificial diverticula formation.

DIVERTICULA OF THE RECTUM

In this portion of the intestinal tract, possibly because of its excellent support and fixation, diverticula seem to be a great rarity. The literature contains very few reports of this condition which may be in part due to the fact that a careful post-mortem examination of the rectum is not regularly made. Inflammatory changes and malignancy have been reported in connection with the few cases recorded and the diagnosis is practically impossible, except after careful dissection of the whole excised rectum.

DIVERTICULA OF THE URETER

In this structure, pouch formation is very rare, apparently only twelve have been recorded in the literature.15 This may be in part due to the difficulty in recognizing these structures by our older retrograde methods. It is just possible that con-tinued use of one of the seven or eight intravenous or oral urographic media will readily demonstrate more of these pouches. Whether these diverticula are congenital or acquired is not known. Obstructive conditions and stones probably lead to some of them, and these seem to be definitely acquired, though in others the structure is identical with that of the ureter, which suggests an embryonic fault, perhaps an undeveloped branch of a bifid ureter. Apparently they occur anywhere from the ureteropelvic junction to the insertion in the bladder and if they are responsible for symptoms and protracted infection, operative excision or more radical procedures will be necessary.

DIVERTICULA OF THE URETHRA

In the urethra, pouch formation is much more frequent than in the ureter. Almost all cases are reported in males, though recently some diverticula have been discovered in the female urethra.²⁰

In 190817 some sixty-nine cases were collected from the Ilterature. They develop in the floor of the urethra and in the great majority of cases are acquired, though some congenital diverticula have been described in the region of the fossa navicularis, probably due to poor union of the penile urethra with that of the glans. Acquired pouches are due to a variety of causes and are found in any part of the floor of the urethra. They may be the result of retention cysts which rupture into the urethra; they may be due to

periurethral suppuration of varying etiology; and they may result from injuries, accidental or operative. As they may lead to retention of infectious material a prethritis may become intractable. Calculi have been encountered tucked away in these pouches. Some rare diverticula have been recorded as large as a fist, though usually they are no larger than a lima bean. Pouches of any size may cause obstruction and retention of urine. The diagnosis is by no means simple, even though the penile diverticula may be palpated along the ventral surface of the organ. Endoscopy and radiography of the urethra, after injection of opaque substances, will establish the diagnosis and site of the pouch. Surgical removal may become necessary and the difficulty of the operation will vary with the location of the pouch.

All the above interesting diverticular formations are rarities in comparison with the three groups that follow. These latter we all encounter with considerable regularity, while the groups described are "rara aves" in most clinics.

DIVERTICULA OF THE ESOPHAGUS

These pouclies, like most diverticula, occur in adults almost exclusively and more frequently in males. They usually develop in a weak area between the lowest circular muscle fibres of the inferior pharyngeal constrictor and the adjacent ohlique fibres on the posterior aspect of the tube. These upper esophageal pouches are therefore really pharyngeal diverticula, though long established custom has called them esophageal or Zenker Diverticula. An occasional case of diverticulum formation has been described where the pouch was just cephalad to the diaphragm. Between these two areas near the level of the left bronchus, traction pouches develop as a result of adjacent lymphatic or mediastinal disease which pulls up on the esophagus. The former type has long been recognized as a "pulsion" diverticulum and the latter as a "traction" diverticulum. The study of these pouches has to some extent affected the interpretation and nomenclature of diverticulosis in other parts.

Those diverticula that develop in the upper part of the tube, in the hypopharynx, usually present on the left side of the neck and may grow into the thoracic cavity. They show in their walls mucosa and submucosa covered by a more or less thick fibrons adventitia. If long standing inflammation has been present, they may become quite adherent to the adjacent structures, but usually are readily freed, being loosely attached. The mucosal side may show varying degrees of inflammation, secondary thickening, ulceration, or neoplastic changes. Rarely, if not instrumented, does perforation take place. These pouches produce symptoms by pressure on the adjacent esophagus and by reflex spasm of its superior sphineter (the circupliaryngeus muscle) as well as

by the fermentation and putrefaction of the food that stagnates in them. Obstruction to swallowing and slowly developing inanition are the outstanding symptoms. Dysphagia and the discharge of ingested food by pressure on the more or less definite tumefaction on the side of the neck are characteristic of the disease. Instrumental diagnosis with sounds or bougies is rarely necessary, since esophagoscopy and radiography are avail-Roentgenological observation and films after barium meals have displaced almost completely all the earlier diagnostic procedures, though esophagoscopy with proper instruments is more valuable in determining the extent and character of the changes in the mucosa lining the As many of these cases come for diverticulum. treatment in varying degrees of malnutrition, they may have to be built up before any radical therapy can be instituted. Medical treatment and even instrumental stretching of the more or less spastic and deformed entrance of the esophagus adjacent to the neck of the diverticulum have rarely had any lasting influence. Operative excision alone seems to promise real definitive cure. Preoperative feedings through a small calibred tube introduced through the nostril into the stomach, using if necessary the string technic to guide the tube past the diverticulum, should be tried before resorting to gastrostomy in cases with severe or extreme inanition caused by long standing obstruction. The endoscopic route for removal by invagination or for establishing a lateral communication between diverticulum and esophagus seem too dangerous to be recommended. Even if peri-esophagitis, cellulitis and mediastinitis could be avoided, recurrence or palliation is the best that such methods could offer. In larger pouches, excision in one or two steps seems the only rational procedure. Though one group of surgeons favors the one method and another favors the other, it is difficult to be convinced that the mortality of the one-step¹⁸ is greater than that of the two-step procedure and that fisulæ are not much more frequent after the twostep operation than after the one-step. The various refinements of these operations need not be discussed at present. It must be apparent that as far as recurrence is concerned, a clean cut one-step excision without interference with the esophageal lumen either by traction or by suture should guard the patient against future trouble. The dangers of cellulitis and pulmonary complications must be reckoned with in all surgical procedures on these more or less infected pouches.

Those rare diverticula near the lower end of the esophagus are rarely encountered and very rarely grow to any size. Symptoms also are unusual unless cardiospasm is present. In one recent case of this type, care in diet and antispasmodics gave relief. In the very unusual larger pouches, various operations, excising (W. Meyer and Sauerbruch), or anastomosing the pouch with the stomach have been suggested but as far as I could review the literature, only two excisions and one anastomosis (Henschen) have been performed successfully in diverticula of the lower end above the diaphragm.

In the mid region, the small traction diverticula also rarely cause symptoms, even though autopsy examinations show them to be the most frequent type in the esophagus. They usually are composed of the walls of this organ, and lie horizontally or run obliquely upward towards the lymph packet that has distorted the esophagus. Occasionally, if they are so placed that food can enter them, they may enlarge under the influence of pulsion and a so-called pulsion traction pouch develops. The diagnosis of these diverticula and those at the lower end of the esophagus are made by radioscopy. In the absence of symptoms, no therapy is called for, except possibly dietetic management.

DIVERTICULA OF THE COLON

The group of colonic diverticula constitute one of the most important manifestations of this pathological entity. It took ages before inflammatory processes in the right iliac fossa were properly explained and connected with inflammation of the appendix and it took even longer before similar processes in the left iliac fossa were recognized as due to diverticulitis of the lower colon. These diverticula are very frequent, occurring in five to ten per cent of all adults and may occur in any part of the colon from the cecum to the rectum. They are almost invariably multiple and frequently very numerous. small percentage of diverticula seem to produce symptoms. 10 At times, diverticula in the small intestines are found associated with those in the colon. In the sigmoid and descending colon, they occur most frequently and it is here that inflammatory changes are most commonly found. Although this is a disease of adult life, a few cases of colonic diverticula have been found in the young. Males are more frequently affected and most patients complain of flatulence or of constipation. Apparently these pouches are herniations of the mucosa through weakened areas of the intestinal wall, and develop either along the longitudinal bands, into the appendices epiploicæ, or into the mesenteric attachment as the result of pressure changes within the colonic reservoir above a torpid rectum or a spastic, tight sphinc-They rarely are larger than cherries and Intestinal contents collect often much smaller. in these pockets and owing to the narrow necks of the diverticula, as well as to the almost complete lack of musculature, stagnation and inspis-This favors local irritation, insation result. flammation, and ulceration, with fibrous tissue reaction. If these processes are too rapid for nature's reaction, the ulceration may lead to perforation into the peritoneal cavity or retroperitoneally,

which fortunately is a rare occurrence. Usually the process is slow, diverticulitis leads to peridiverticulitis with local suppuration or interstitial inflammation in the colonic wall and mesentery. Some thirty years ago, I happened to see two cases of abscess in and about the sigmoid, associated with tumefaction and incomplete obstruction, which had simulated clinically, carcinoma of the lower bowel. On drainage of the perisigmoid abscess, the condition slowly cleared up. These unusual cases seemed quite inexplicable at the time, but shortly thereafter, while engaged in autopsy work in Prague, I found the probable explanation for the above cases in the inflammatory reaction that I saw in and about the sigmoid in infected diverticula. It was as a result of these observations that I collected all the clinical and pathological data already recorded, and published them in 1904. In some cases, the inflammatory reaction leads to such extensive tumefaction with obstruction of the lumen that the clinical picture suggests neoplasm. At times the inflamed sigmoid becomes adherent to adjacent viscera, most commonly the bladder, and a fistula develops between these organs. Rarely malignancy arises in these diverticula, and then both the clinical and the pathological diagnosis may be most difficult.

The diagnosis of diverticula of the colon may be suspected when the above pathological changes are in evidence, but without the colonie x-ray and the barium meal, the diagnosis is at best only a good guess. Sigmoidoscopy is in general useless, except in so far as it may detect a diseased mucosa which is rarely present in diverticulitis, as this produces interstitial mural changes rather than changes in the mucosa. Direct inspection of the bowel may discover a neoplasm, which may account for the symptoms and thus establish the diagnosis. In those rare cases of sigmoido-vesical fistula, cystoscopy with or without excision of mucosa adjacent to the opening in the bladder may be helpful in excluding tuberculosis and carcinoma, which are the other more common diseases that lead to the condition. The radiographic picture is particularly clear after the bowel is evacuated and the residue that remains in the pouches is visualized as opaque circular shadows along the course of the colon. Whether the prediverticular stage can be recognized radiographically is open to doubt. Its characteristic appearance is said to manifest itself by loss of normal segmentation, more rigid outline and small convexities in the outline.20

For a complete radiological study, both the meal and the enema seem indicated. Following the barium meal, the above globular bodies may be detected many days after the rest of the colon is empty. With the barium enema, similar pictures may be seen after evacuation, and during the filling one usually sees the irregular stockade-like or serrated outline of the involved areas.²¹

As said above, only a small percentage of di-

verticula become inflamed and require either medical or surgical treatment. The former consists in simple diet with lubrication and irrigation of the intestine, so as to put the parts at rest and prevent further irritation. The latter consists in meeting the conditions presented at operation, such as drainage of local abscesses, or treatment of a free perforation by closure and drainage, eccostomy to put the inflamed sigmoid or colon at rest; in suitable cases a Vorlagerung of the involved gut with secondary excision, or separation of bladder and sigmoid in fistulous cases with elosure of both perforations and interposition of omentum to prevent re-anastomosis of the two involved and much-indurated viscera.

DIVERTICULA OF THE URINARY BLADDER

Next to the group just described, diverticula of the urinary bladder are the most frequent seen in the modern clinic. They occur in all ages, though definitely much more common in adults and advanced life. They are very rare in the female, probably because of the rarity of obstructive conditions at the bladder outlet. The small multiple hernial protrusions of the mucosa, seen so often in prostatic obstruction, resemble closely the sigmoid and colonic cases just described. They are found all over the bladder convexity and develop between separated hypertrophied bands of musculature. In the cystogram, they may produce a scrrated outline very similar to that seen in the sigmoid, but here the serration is definitely due to the filled diverticula and are much more blunted or rounded. Infection with perforation into the free peritoneal cavity is very rare, but perivesical inflammation is probably much more frequent than is realized in the clinic. Stones corresponding in size to these small pouches may develop in them and in one case, by pressure here and there against the bladder wall with a blunt instrument within the viscus, I have squeezed out many dozen small stones without any difficulty, each stone jumping out into the bladder like a pea out of its pod. All these diverticula seem to be acquired and secondary to obstruction to the outflow of urine.

In contrast to these small diverticula which rarely are larger than a walnut and usually much smaller, are those interesting large diverticula which are at times single, but often multiple, that seem to be congenital in origin. They occur in young children as well as in adult life. They may be enormous, holding five litres of urine. One that I removed was as large as the distended bladder and held twenty-six ounces. They probably owe their origin to some congenital anlage or malformation and usually grow in size as the individual ages. Obstruction to the outflow of urine from the bladder is not always present, but when it is, growth is probably accelerated and large diverticula present. These diverticula always arise near the ureteral orifices, and as they

grow they occasionally draw the ureteral mound and its orifice into the sac. Insertion of the ureter into the diverticulum at some distance from the bladder wall is much less common, only one such case having been encountered by me. Inflammation in these diverticula is liable to develop, and peridiverticulitis may involve the adjacent lowermost ureter so that it seems to be part and parcel of the wall of the sac. Stones, at times collar button stones, part in the diverticulum and part in the bladder, are liable to develop. In other cases, facetted groups or single stones are found in these pouches. Leukoplakia and neoplasms arising from the diseased mucosa of these diverticula are by no means rarities. Infection in these structures is practically uncontrollable, as they usually have little or no musculature, if they are of any size, and therefore they cannot empty themselves. Their presence disturbs the bladder mechanism as the detrusor forces the urine into the diverticular cavity at each micturition. This disturbance is usually followed by hypertrophy of the bladder musculature and occasionally by giving way of the ureter orifices and dilatation of the upper tract on one or both sides. In one case of large diverticulum which was filled for roentgen study with argyrol, I found the argyrol still in the diverticulum thirty-five days later, though the patient had bladder irrigations almost daily. The presence of such an infected diverticulum may prevent the smooth closure of a suprapubic bladder wound.

Unless infection is present, the presence of these pouches may never be suspected. Rarely they are recognized by palpation either in the suprapubic area where a spherical mass may be palpated after micturition. Several cases in children were detected in this way. By rectum one can also at times feel such a filled diverticulum. The only reliable diagnostic aids, however, are the cystoscopic examination and the roentgenological demonstration with opaque fluids, such as sodium iodide, sodium bromide and the like, the pictures being taken antero-posteriorly and obliquely. Frequently, after emptying the bladder, an aerogram of this organ will show the diverticula still fairly well filled with the opaque solution, while the bladder, is distended with contusting air, With the cystoscope, one regularly sees the dark orifice of the diverticulum, though in a few cases, what looks like a sphincteric closure may temporarily prevent visualization of the orifice.

In the first group of bladder diverticula, so frequently seen in prostatic cases, rarely is surgical treatment required, unless they harbor stones

or are unusually large. Persistent moderate pyuria following adequate relief of obstruction is frequently due to persistent infection in these pockets. On the other hand, the second group demands surgical excision with adequate care of the ureter, if it is involved in the process. Numerous methods of approach for the operative removal have been suggested, both from within the bladder and from without. My impression is that surgical exposure from without, after adequate mobilization of the bladder with visualization of the ureter or ureters, with careful external suturing of the bladder wall is the best approach and the surest method of preventing a recurrence. Almost twenty years ago, in doing the operation in this way I became acquainted with the procedure of complete mobilization of the bladder, stripping it out of its peritoneal covering and its perivesical tissues, which technic I have used since then in my operative work in bladder resections for infiltrating carcinomata. It must be evident that any method that fails to expose the orifice of the diverticulum from outside the bladder will not permit of accurate closure of the neck and predisposes to recurrence, a sequence that has been reported every once in a while in the literature. If the ureter opens near the orifice, it can be-turned into the bladder with a small flap to which it is attached. In those rare cases, when it opens into the diverticulum at some distance from the bladder wall, it can be covered with a triangular flap of diverticular wall and thus introduced into the viscus before the orifice in the bladder wall is closed from without. This triangular flap has its base at the bladder, and as the ureter orifice is introduced into the viscus, the edges of the flap are sewed over the exposed ureter, which then projects well into the bladder. The results of these operations are highly satisfactory and the mortality is low.22

From this review it is apparent:

1. That diverticula of the alimentary and urinary tracts are much more common than was thought only a few years ago.

2. That diverticula may produce clinical symptoms and with our latest methods of investigation they can almost regularly be recognized.

3. That relief by surgical removal or analogous procedures is usually obtainable, without undue

risk.

4. That diverticula in general are acquired. though in many cases they may be congenital or due to a congenital "anlage" and develop only when the factors that make for an acquired diverticulum are present.

THE OECOS—THE DEMOS—AND MEDICINE

By IAGO GALDSTON, M.D., NEW YORK, N. Y.

An exposition of the fundamental principles underlying the activities of the foint Medical Information Bureau of the New York Academy of Medicine, and the Medical Society of the County of New York, by its Executive Secretary. Read before the Philadelphia County Medical Society, Pedrary 8, 1903.

THE term economics is derived from the Greek Oecos, meaning household; and the science of economics as first formulated by Xenophon, and later by Aristotic, concerned itself with the efficient management of the house-

Aristotle, of course, was not interested in giving helpful hints to the busy housewife. His concern with the household was due to the fact that in it is to be found the prototype of the State, which in his day meant the Hellenic City, and in ours means the World as a whole. And that which makes the household the prototype of the State is the division of labor witnessed therein.

Aristotle, as is witnessed in the Occonomica attributed to him, fully appreciated the productive increment resulting from the division of labor, but he saw likewise the need for harmony and cooperation among the specialized elements

of the household.

The science of economics has made much progress since the days of Aristotle, so much, in fact, that the oecos has been practically completely forgotten. Today economists are more concerned with business cycles and with theories of value and of exchange, than they are with the household. In this respect, they are like certain of our pathologist brethren who, engrossed in the phenomena of the abnormal, completely forget the patient.

The Larger Occos-the State

However, in the last analysis, in medicine it is the patient with whom we must be concerned; and in economics it is the household. But by household we must undestand not merely a man and his dependents, but our larger social organism: the State, the Nation, and indeed the World. For herein lie both the source of many of our difficulties and the promise of our salvation, that modern civilized society, culturally and economically, has the nature of a household, and is so complex and yet so integrated, that injury or embarrassment in any one part or division, is quickly and painfully reflected in every other part.

Modern technologic developments, the extractdinary division of labor, the complexity of our economic system, have all served to tie are angether by so many bonds that any significant fiturbance anywhere in our extensive realm 1 ... immediate reverberations throughout the civilized world. Very few of our policies statesmen, and economists, however, appear : aware of this fact, or allow its realization . * fluence their treatment of the social and eproblems that beset us. Instead of vitaproblems against the background π : their furthest consequences and governed by the mere expedient and during the last quarter of ze witnessed the baleful results of

But this fault is to be witer manner in which we face to problems, but also in the and mon, everyday life. , .

Modern society is a . many metamerer incomes grades, but also and to function. Inch chig Dana nadil and er 🗽 1. tically all almost

ایر

insulate themselves against the rest of the social organism by developing a specialized language, and largely in consequence, a unique and restricted viewpoint. Practically all of them seek special group and class privileges, unmindful of the fact that such asocial endeavors handicap and injure the large social organism of which they are a part.

This paradoxical, incongruous condition in our socio-economic life has been brilliantly described and analyzed by our little appreciated but great American thinker, Thorstein Veblen, in his "Theory of the Leisure Class," and in his series of essays entitled "The Place of Science in Modern Civilization." The paradox as he demonstrates, lies in this, that technologically and economically we are all most interdependent; but ideologically we are divided into antipathetic, irreconcilable groups. And in this connection it is disheartening to recall that almost twenty-five hundred years ago, Demosthenes and Isocrates. addressing the Athenians, sustained the burden of the same thesis. We know the fate of the Hellenic world exsanguinated by the Peloponnesian wars, and there are some, notably Oswald Spengler in his "Decline of the West," who see a like fate ahead of us.

I, for one, do not share this pessimistic view of the future, and precisely for the reason that modern social and economic life has in fact become so specialized and so interdependent. Modern society is like an animal with highly specialized systems and organs, and with a nervous system in which the association tracts are well developed. It is more exquisitely sensitive than are the lower forms of animals to unfavorable conditions, but it can execute the necessary adjustments more expeditiously and more appropriately.

Medicine and the Oecos

Medicine as a science and profession shares in a substantial measure the faults and shortcomings of current society. In fact, its insularity, its self-imposed isolation from the rest of the living world, is probably epic. We have for many decades gone on our way unmindful and indifferent to the rest of the world, wrapped in our science and confined in our small cubicle. Recently we have been awakened with a jolt. We discover, to our surprise, that the inexorable laws of economics also affect our little portion of the universe, showing no regard for the sanctity or dignity of our profession.

Within the last half century we have witnessed the development of industrial medicine, of life insurance medicine, of workman's compensation; we have seen hospitals, dispensaries, and departments of health grow phenomenally; and more recently we have been startled by the intensive

agitation for state medicine.

We are bewildered by these discoveries and

some of us are not a little resentful. We are also at a loss on what to do. Perhaps at this juncture a little philosophical reflection will help us see the situation in its correct perspective.

I believe it was Aristotle who said that in order to attain perfection, the philosopher must become a physician, and the physician a philosopher. How profoundly wise this dictum is can best be appreciated by those who have witnessed the sterile excursions of philosophy into the arid realms of metaphysics, where nothing of the human prevails. The counterpart of this may be seen in those schools of medicine wherein there is a complete want of philosophy. In this connection I recall the astute words of Professor Siegrist when commenting on the relative fruitlessness of our many years' search for the cause of cancer. He said (I quote him approximately), "The speculative era in medicine is fortunately Today we are in an age of objective Yet every scientific project must have science. its hypothesis; and an hypothesis is a speculation founded on experience. That is philosophy. Perhaps the fault in medicine is due to our want of philosophy, and to the aridity of that little which we follow."

There is indeed much want of philosophy in our ranks. Science, our young wife, has turned our mother, philosophy, out of our house, and has usurped all of our attention. We are ashamed to philosophize. It is no longer stylish. We honor the protocols of the laboratory, even though they be devoted to the merest minutia of minutiæ, but we frown upon the encompassing speculations of the mind. Socrates would find few willing listeners among our ranks, and Plato would be challenged for his lack of graphs and charts.

And yet, it was not always so in medicine. Virchow was not so indifferent to the affairs of men; neither was Abraham Jacoby. In your own great city there lived in the early days of our republic men who were physicians, competent and famous too, to whom, in the spirit of the Latin poet, "Nothing human was alien." Today we have few Virchows, few Jacobis. We have had too few of them in the last hundred years. During this period we have witnessed the most phenomenal changes in our social and economic ex-We, who should have been most competent to judge of the trends, who should have raised our voices in warning and protest, were mute. Our eyes were glued to the microscope, our ears plugged by the stethoscope, our minds too occupied with disease to see the broader phases of human well-being. Now we reap with the rest of the world the bitter fruit of our sowing.

Medical Economics

Economics formerly had no place in our programs or deliberations; and now it is almost com-

monplace. Unfortunately, however, much of the medical economics now discussed and presented is narrow, almost predatory in nature. The problems of our profession are deliberated upon from the dollar and cents viewpoint and not from that of the oecos, the household of lumanity. Many physicians still fail to see that the interests of our profession are tied up with those of the state and of mankind; that our problems are part of the larger problems of humanity; that our difficulties will be solved only as the larger economic problems are settled. Furthermore, few of us realize that we can serve ourselves best by contributing according to our ability to the settlement of the difficulties which today beset all of mankind.

Undoubtedly this is a very large order, too large, in fact, for execution. But then it is not given as an order. It is presented as a background, as a chart of the troubled seas. If one of our leading medical statesmen had understood as much, he would not have seen this depression silver lined by the fact that unemployed parents can now spend more time with their children; nor would he, in the naive spirit of Marie Antoinette, have invited the workless to visit our national parks. The course of a ship is charted in a direct line, but the helmsman tacks to wind and current. We have at hand many problems which require our attention, and to which we can effectively apply our energies. Let us do so, bearing in mind the large stage upon which we play our part.

The Demos-the Citizenry

Consider this, for example. In order that we might, as a profession, participate in the deliberations of the oecos, our economic and social household, we must have an organ of articulation, a means for expression, the machinery with which to make ourselves heard and understood. In so far as we live in a democracy, we must address ourselves to the demos, we must speak its language and talk into its ear. The demos has sensitive cars, and it has an expressive language. We have not, however, cultivated the language of the man in the street, nor have we addressed ourselves to him. Let us confess that a good deal of this was due to our snobbish conceit, and to our contempt for the demos. We write Latin, and the demos speaks a jargon. We are objective scientists and the demos is blown about by the wild winds of ignorance and credulity. But as it is written in I Corinthians XII "The body is not one member but many, and the eye cannot say unto the hand I have no need of thee; nor again the head to the feet, I have no need of you." The body politic and economic is, in this respect, not unlike the body human.

Today medicine must make itself heard, not merely by choice but by necessity. We as a profession must make ourselves heard and understood in the council of the oecos.

For the days when medicine, like the priesthood, was a profession apart and above the rest of the community, are gone. Our profession is ruled and legislated by the common lawmakers. We are scrutinized and catechized from the day we enroll for our medical studies to the time we graduate and enter upon practice. We must enroll with the elerk of our community, and in certain states every year thereafter. The very practice of our profession is legislated, so that the spiritus frumenti which we may prescribe for our patients is dictated not by medical experience, but by laws written in Washington.

The public no longer regards us as a privileged group. They speak of us not with bated but with leated breath. Witness the numerous articles which have appeared in the public press, in which laymen have scourged our profession, charging us with all the multitudinous sins of the modern age. We have been driven from the honored and revered estate of former years to where we have to fight for the opportunity to practice our profession as free individuals. There is much talk of state medicine, of health insurance, and of various and sundry schemes for the reorganization of medical practice and in many of these proposals the medical profession appears to be a pawn in the hands of alien players.

And in the midst of this stands the giant, the medical profession, tongue-tied, if not completely inarticulate. To meet the challenge of this situation, the medical profession needs an articulate

voice and an integrated intelligence.

Medicine and the Demos

The greatness of Athens was not in the Acropolis, but in its market place,—the amphitheatre of Socrates and the university of the Athenian. It was there that men foregathered to exchange thoughts, to listen to the gadfly questionings of the bald-pated philosopher and to swap experiences on various Hippocratic practitioners.

We live today in a greater Athens, in which there is a bigger market place, and our voice should be heard in the babble of the populace, not only that we might defend ourselves against calumny and set men aright in their judgment of us, but that we might also serve the community by bringing to it that knowledge which will serve

better and longer life.

The American public has an insatiable curiosity; and curiosity is the fertile muck in which the rare flower of intelligence flourishes. The public demands, as is its prerogative, to know what is going on in the community, in medicine as in politics. When the King of Siam comes to America to be operated upon, there arise in the public mind a hundred questons, most of which are legitimate and not a few of which are intelligent and useful. When, by the artifices of the publicist a sensation is created in the alleged "one

chance in a million" of success of a certain operation, we are duty bound to enlighten the public and to prick this malicious and fanciful bubble. When a spectacular announcement is made that a cure for cancer has been discovered on the Pacific coast, can we blame the public for its clamor to be informed? Can we afford to fail in the duty to ourselves and to the public that demands information, by enveloping ourselves with the mouldy cloak of dignified silence? Our relation to the public, however, is not one-sided. They are not eternally our debtors. With increasing frequency we are compelled to turn to them, seeking their aid in furthering and defending our profession.

But recently there was issued to the public the report of the Committee on the Costs of Medical Care, and a little later that of the Council of Medical Education. Both of these reports affect us deeply, and not only nationally but locally too. for there cannot be any one universally suitable solution to any of the major medical problems. We needs must comment upon and answer these reports. We must make our side heard, and understood too. We must have for this the sympathy and the good will of the public. More immediately we must have the sympathy and understanding of the press, of the radio, and of all other agencies promoting public knowledge and moulding public opinion. Love may blossom overnight, but sympathy and understanding require long cultivation. The present is none too soon to set ourselves to this task. For even as at this hour we need a telling voice in the affairs of men, so with the passing of time will the need become more urgent.

Medical Information Bureau

And now we come to the practical phase of the discourse: How can Medicine make itself heard

and understood in the community?

The precise method must vary from place to place as the circumstances differ. In New York City we have a Bureau with an executive staff devoting all of its time to the dissemination of medical information. That this information might be authentic and representative of the consensus of opinion in the medical profession, there is a supervising Executive Committee which is constantly in touch with the executive staff.

The credo of the Medical Information Bureau was printed in the special publication of the New York Academy of Medicine in November, 1928,

in these words:

"From its earliest days the profession of medicine has been governed by a code of ethies which has served to maintain the lofty ideals of the followers of Æsculapius. Unhappily, this eode has also served to insulate the profession against intimate contact with the public.

"Whatever may have been the forces and motives that moved the early law makers of medicine to instill an element of secrecy and aloofness into the governing principles of the profession, certain it is that the best interests of the physician and of the public are no longer served by this attitude. The recent and phenomenal progress of modern medicine, and particularly of preventive medicine, necessitates the development of a direct and intimate channel of communication between the practitioner and the community. This is essential, not only that the public may learn to take advantage of the constant advances of modern medicine, but to the end that it may be protected against the hordes of charlatans, quacks and misguided zealots who, strange to say, thrive more than ever in this day of presumptive enlightenment.

"In appreciation of the needs of our day and society, the New York Academy of Medicine and the Medical Society of the County of New York have established a joint Medical Information Bureau. The aims of this Bureau are to facilitate the dissemination of authentic information on medical and public health matters, to stem and curtail quackery and to promote a better understanding between the public and organized medicine. "The Medical Information Bureau is supervised by a

"The Medical Information Bureau is supervised by a Committee representing equally the Academy and the County Society. It is served by a body of over one hundred consultants competent to give expert opinion on a variety of questions relating to their specialties. The full resources in judgment, knowledge and experience of the medical profession in New York are 'on tap' to aid its purpose."

The Medical Information Bureau has been in operation now almost five years. It has been eminently successful in achieving its objectives. It has secured the good will and cooperation of the press, the radio broadcasting stations, and certain other agencies which carry news and information of a medical nature. It has succeeded in presenting to the public through the press important scientific papers presented at the New York Academy of Medicine, and to give notice of various discussions of a social nature. It has assisted newspapers in checking on the authenticity of news items which they have received from various parts of the world, and it has helped them in the preparation of feature articles of a medical nature.

The Medical Information Bureau has not, however, and this is important, set itself up as censor. It has not sought for publicity, in its undesirable phases, for any of the activities of the individual physicians connected with the New York Academy of Medicine or the Medical Society of the County of New York, nor has it publicized these organizations.

Lastly, it has never aggressively promoted medical news. It has released to the press and other news agencies the medical information available, leaving it to them to decide what is news.

FIBROIDS OF THE UTERUS, THEIR RECOGNITION AND TREATMENT By ROBERT T. FRANK, M.D., NEW YORK, N. Y.

From Private Practice and the Gynecological Service of the Mount Sinai Hospital, New York, N. Y.

THE general practitioner as well as the gynecologist, when he discovers or is told that one of his patients has uterine fibroids, should know what advice to give. Frequently I am asked by colleagues, "What should I tell a woman who has asymptomatic fibroids?"

This is not a simple question to answer. When dealing with a malignant growth, it is evident that if the condition is still operable, inmediate operation or radiotherapy must be advised. This does not apply to fibroids, which are benign growths, and in the vast majority of instances,

never become malignant.

Statistics: Of interest in this connection are statistics gathered by me in 1922, based on over 500 cases, as well as those of Lockyer of London, based upon a similar number, both showing a surprising concordance in the method of treatment required for these fibroid growths.1 In my private practice, although it consists largely of referred cases, approximately only 50 per cent of fibroids required operation. The other 50 per cent, consisting mainly of small to medium sized accidentally discovered tumors, merely required observation. Some recent statistics gathered from my service at Mount Sinai Hospital, show almost analogous statistics as can be noted in Tables 1 and 2. Of the 134 patients with fibroids, sent to the hospital, 44.7 per cent required either no operation, or eurettage, or still less frequently, curettage and radiotherapy. The remainder, only 55.3 per cent, were subjected to laparotomy.

Period of Observation. In some instances I have watched women for 25 years or more, seeing them at first twice a year, later once a year, without ever having to advise any intervention. A certain number of these patients, because of increased amount of menstruation, either menorrhagia, or metrorrhagia have been euretted. Frequently this purely diagnostic measure has given permanent or if not, at least temporary relief for months or years. A large number of these fibroid bearers have entered the menopause while under observation and almost regularly the fibroids have diminished in size or disappeared, as far as bimanual examination could determine.

In a certain number of those observed over a period of years, however, the fibroids have increased in size or the tumors have become submucous and extruded from the cervix, or the bleeding has increased to such an extent as to require operative intervention or x-ray treatment. As will be seen from Table I, bleeding is the most prominent symptom in small growths.

The mere presence of fibroids does not necessitate any intervention unless their size and distri-

¹ Frank, R. T. The Treatment of Uterine Fibroids; Based on a Series of Five Hundred Cases. Colorada Medicine, October, 1922.

bution or the symptoms of bleeding, pain, or pressure obliges us to intervene (See Table 1).

Whether a fibroid can be safely observed or should be operated upon without undue delay, requires an amount of experience which the fewest general practitioners can acquire, and therefore conservative expert specialistic advice should be sought. Too many gynecologists, unfortunately still advise operation unnecessarily and routinely in cases in which the growths are harmless and the operation not without danger.

Commonest Indications for Operation. Of the fibroids which require operative, or radiotherapeutic treatment, the commonest are those which have attained a size of 3 months or larger, using the size of the pregnant uterus as a convenient standard of measurement. Intramural growths occasion less trouble than any other group. Subserous tumors, too, may remain asymptomatic unless they become pedunculated and the pedicle shows signs of attenuation or twisting. Under these circumstances, fortunately rare, peritoneal disturbances set in. Fibroids which develop into the cavity of the uterus, submucous, are the most troublesome, as they almost invariably produce profuse and irregular bleeding, are subject to infection and sloughing, or by their action as foreign bodies, produce painful uterine contractions, frequently followed by extrusion of the fibroids into the cervical canal or vagina where the danger of infection or sloughing is even greater. Intraligamentous fibroids developing laterally, should not be allowed to attain large size as not only do they displace the uterus, but likewise occasion pressure symptoms, and when large, offer great technical difficulties in their removal. The same applies to another subperitoneal variety of development, namely cervical fibroids, and the rare variety which develops between cervix and bladder. Let me briefly present a few cases which show how varied the advice and how diverse the procedure must be in a given instance.

Average Case of Fibroids-Menorrhagia and Metrorrhagia, Curettage, Menopause

Case 1. V. E. 49 years of age. Complaining of tired feeling, leucorrhea. The periods had become more profuse and more frequent in the last 1½ years. The uterus was felt 3 fingers above the symphysis. There was a polyp the size of a pigeon's egg (Fig. 1). Gurettage was advised. The polyp was avulsed, the uterine cavity explored, but aside from a fibroid enlarging the uterus to the size of a 2 months' pregnancy, no other abnormality was discovered. This patient has been watched for a year and a half. The normal menopause has set in and the fibroid shows signs of shrinking. The patient is to be seen every 3 months for the present.

Small Fibroids-16 Years' Observation

Case 2. L. H. First seen at the age of 22 years in 1911. Difficult confinement, normal uterus. Five years later small fibroids were discovered. Nothing further done. 1919, at age of 30, same findings. One year ago, because of increasing amount and frequency of

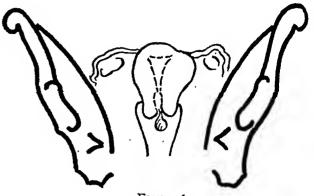

Figure 1
Case 1. Protruding polyp.

menstruation, the patient came for re-examination and the uterus was found about the size of 10 weeks' gravidity. In the last year, now 43 years old, the fibroids have remained approximately stationary (Fig. 2).

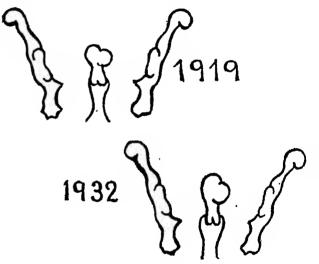

FIGURE 2

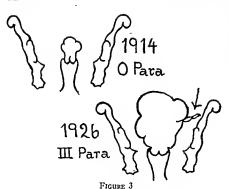

Case 2. No growth in thirteen years.

Fibroids: Observed 12 Years: New Indications:

Case 3. G. H. 28 years of age. No children Two abortions, last one 4 months ago. Since that time she has run some temperature and had pain on the right side. Uterus size of 2½ months' pregnancy. Observation counseled. Nine years later, operated upon for acute appendicitis by another surgeon, drainage required for 3 weeks. Twelve years after first being seen, the uterus was approximately the size of 3½ months' pregnancy. She was suffering from menorrhagia, abdominal cramps and severe backache. Considerable intestinal disturbance. Barium enema showed a marked extra-intestinal pressure exerted upon the sigmoid. At operation the uterus was removed and an infiltrated left mesosalpinx twisting the tube and compressing the sigmoid was found. After the mesosalpinx had been cut, the sigmoid resumed its normal filling (Fig. 3).

Fibroids—Purulent Bronchitis: X-ray and Radium Observation: Operation

Case 4. D. S. 36 years. Two children, last 10 years ago. Chronic bronchitis for years. Accidental find of large uterine tumor. Treated by radium and x-ray be-

Case 3. Arrow points to infiltrated left mesosalpinx constricting the sigmoid.

cause of chronic bronchitis, by another surgeon. Has dyspnea on exertion. Abdomen increasing. Uterus the size of a 5 months' gravidity, hard, nodular, somewhat cystic posteriorly. Again given x-ray. Again seen 3 months later by me. Still stains irregularly. Feet swollen. Persistent bronchitis. Tumor has increased, rising from 1 finger below mnhilicus to above umbilicus. Seen 2 months later. Has lost 10 pounds. Bronchitis the same. Still bleeds, Fibroids still increasing (Fig. 4). One month later, after consultation with a chest specialist, operated under spinal anesthesia. Supravaginal hysterectomy, double salphingo-oophorectomy. Uneventful convalescence. Bronchitis much improved.

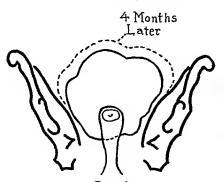

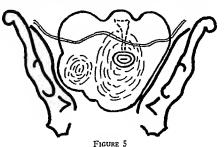

FIGURE 4

Case 4. Rapid growth of fibroid.

Pibroids: Loss of Health: Fever: Operation

Case 5. H. H. 49 years of age. Seen in consultation because of persistent temperature, retention of urine, and accidental discovery of an abdominal mass. The mass reached half way to the umbilicus and the entire pelvic diaphragm was pushed toward the vulva by multiple masses which impinged on the rectum and filled the entire lower pelvis. The diagnosis of an impacted cervical fibroid probably undergoing sarcomatous degeneration was made and immediate operation advised. Operation 10 days later showed a large cervical fibroid impacted in the pelvis and undergoing carneous degeneration (Fig. 5).

Case 5. Impacted cervical fibroid.

Emergency Operation for Fibroids: Transfusion

Case 6. A. T. 33 years. Admitted as emergency to private pavilion, exsanguinated woman. Hemoglobin 35 per cent. Bleeding profusely, At once taken to operating room after a billiard ball sized tumor was found projecting into the vagina. Enucleation from below of a submucous fibroid partly born into vagina (Fig. 6). Direct transfusion of 500 c.c. of blood. Rapid recovery. This patient has been watched for 5 years. Her menstruation has become normal. The uterus is of moderate size.

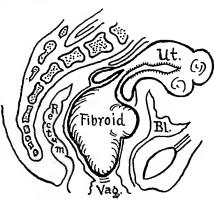

FIGURE 6
Case 6. Extruding fibroid, with hemorrhage.

These six cases illustrate many of the problems encountered both by practitioner and specialist. When the necessity for intervention has been established, the type of treatment must be determined.

Indications for Radiatherapy. Of the 50 to 55 per cent of fibroids which require intervention,

approximately 15 to 20 per cent can be treated by means of radiotherapy. In my experience, x-ray is preferable because it avoids any intrauterine manipulation, permits of more accurate dosage, and avoids local trouble, particularly the persistent leucorrhea that follows radium insertion into the uterine cavity.

In the group amenable to radiation are included in particular the small growths less than 3 months in size, if a submucous site can be excluded and the menstrual symptoms are those of excessive bleeding. Personally I refuse to sanction radiotherapy without a preliminary curettage, not only in order to recognize corporeal malignancy, but also if possible, to exclude the presence of a submucous growth which ordinarily contraindicates radiotherapeutic measures.

We are forced at times to extend the indications for radiotherapy to a group of patients whose fibroids are unfavorable, because of their size and submucous situation, for this type of treatment, but in whom the special indications of excessive operative risks due to pulmonary, cardiorenal or other grave systematic diseases make operation extra-hazardous. I would also include very obese and short necked women who do not tolerate laparotomy well and in whom it has been found that the incidence of thrombosis and embolism is particularly high.

Radiotherapy, which induces the premature menopause, if carried beyond a certain degree, is to be regarded as radical treatment but I limit the designation of major operation to those cases in which the abdomen requires opening per vaginam or from above.

Indication for Major Interventions. The indications for such operative measures are supplied by the dimension attained, continued growth, especially if the increase in size is found to be rapid, or pain and pressure symptoms upon the bladder The size of a growth, if it exceeds the dimensions of a 4 months' pregnancy, usually demands operation per se. Here, in parenthesis, I would say that the mere elevation of a tumor into the abdomen, does not show the exact size unless controlled by bimanual examination, for certain tumors may ride entirely above the pelvic brim and therefore rise higher into the abdomen than much larger growths which originate deep in the pelvis. Smaller growths, if complicated by adnexal trouble, adenomyosis or ovarian neoplasms may require operation because of the coincident condition (33.7%, Table 2).

Furthermore, changes within the fibroids, particularly the so-called aseptic carneous degeneration, occurring most frequently during pregnancy, occasions severe pain, which in a number of instances, has been sufficient to necessitate operation even before the termination of gestation. This applies particularly to patients in whom the

process is accompanied by fever and peritoneal symptoms. However, many of these patients, if carefully watched, may be carried through the attack without operation.

In a certain number of cases the rapidity of growth, the constitutional symptoms, the anemia, the persistent bloody or watery discharge, are sufficiently characteristic to permit the suspicion, and in some instances the certainty of malignancy. Sarcomata have been observed in approximately 4 per cent, fundal carcinomata in smaller number. Under these conditions, operation is imperative. For some unexplained reason, we have seen far fewer sarcomata during the last five years than heretofore.

Diagnosis of Unusual Types of Fibroids. Most fibroids are readily diagnosed by their typical configuration, their direct connection with the cervix and fundus of the uterus. Occasionally, however, interesting or misleading findings are noted.

Case 7 was a woman of middle age admitted twice previously to my service at the hospital for symptomless fibroids the size of a 4 months' pregnancy. She was not operated upon because of severe myocarditis. Her third admission was to the medical service with upper abdominal pain. This patient went into shock, with diffuse rigidity, distension and vomiting. The tumor could not be felt. The abdomen was opened with the diagnosis of ruptured tumor, probably ovarian cyst.

At operation I found the omentum adherent to a large subperitoneal growth, the size of a football. (Fig. 7). After freeing the epiploön, I incised the peritoneum and found a thick layer of fat completely enveloping the fibroid. The tumor was readily shelled out, showed no connection with the uterus, but was found attacked to the right round ligament where this band enters the internal ring. The patient has remained well (1½ years).

FIGURE 7

1. Tumor exposed.

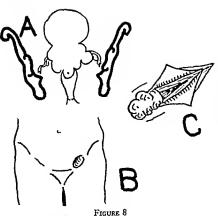

2. F. is the fibroid seen through the incision in the fatty envelope.

3. The relation of the tumor to the round ligament R.L., and the uterus, Ut.

Case 8. Recently I operated upon a private patient for multiple fibroids and incarcerated left inguinal epiplocele. After completing the hysterectomy and closure of the median incision, I cut down upon the inguinal ring. The "hernia" proved to be a fibroid of the round ligament where this structure emerged from the external ring (Fig. 8).

Case 9 was operated upon on my service for large ovarian cyst (Fig. 9). The tumor proved to be a large cystic fibroid (fibro-cyst) containing 2 gallons of fluid

(Fig. 10).

determined mainly at the time of the intervention and, as it is essentially a surgical problem, should be left to the operator. The choice of performing a conservative operation, namely myomectomy for multiple fibroids, may arise. This applies particularly to young women with normal adnexae, who desire to have children. In deciding it must not be forgotten that the most careful myomectomy may be followed sooner or later by recurrence of fibroids, which at the time of operation were of such small size as to escape notice. Where special indications do not exist, most men who are conservative in their diagnosis pre-operatively, find it necessary at operation to perform a hysterectomy. (5.4 per cent of myomectomies in my series.) Myomectomy, too, is a more dangerous operation than hystercctomy, with a more stormy convalescence and greater danger from hemorrhage and peritonitis. It is unwise to promise too definitely to perform a myomectomy as this may prove technically hazardous or impossible. The operator's action must be free.

As far as hysterectomy is concerned, I personally prefer, unless very special conditions obtain, to amputate through the cervix, leaving a cervical stump, because even in the hands of experienced men, complete hysterectomy with the removal of the cervix, entails a greater morbidity and likewise a greater mortality. Removal of the cervix does not guarantee against a vaginal carcinoma. If the cervical canal shows signs of irritation, the endocervical mucosa can be cored out from above without in any way increasing the risk. I give this advice in spite of being well aware of the possible occurrence of "stump cancer," having seen a small number of carcinomata developing in the cervical stump (8 cases). If this rare and unfortunate sequel should occur, we have found this type of tumor particularly blood supply is preserved, my hormonal studies amenable to radiotherapy.

Whether the ovaries are to be removed or retained presents an individual problem in each instance. In women up to 35 years of age, every effort, consistent with safety, should be made to retain the adnexa. After 35 years of age I prefer to perform bilateral salpingo-oophorectomy. In 33.8 per cent in my series, castration was imperatively indicated by associated lesions. effect of retention of the ovaries after hysterectomy is very variable. In a few patients no disturbances occur, in others typical menopausal symptoms develop, in the remainder the climacteric troubles are atypical and of long duration. That the ovaries continue to function, if their have shown conclusively.

The operation of hysterectomy in good hands in well selected cases, entails a mortality of from 1 to 3 per cent, but the best of operators cannot avoid the occasional occurrence of fatal thrombosis and embolism, the occasional post-operative pneumonia, and still more rarely, in spite of every precaution, the occurrence of peritonitis. Consequently, the conscientious surgeon and also the family practitioner, should carefully study and weigh the existence of a major intervention before advising this operation; and in borderline cases, should observe the patient over a considerable period of time before counseling radical measures.

TREATMENT OF HEPATIC CIRRHOSIS WITH INSULIN

A PRELIMINARY REPORT WITH CASE HISTORIES*

By JOHN McCABE, M.D., AND JAMES FINLAY HART, M.D., NEW YORK, N. Y.

TEPATIC cirrhosis is a common, chronic, progressive, fatal disease characterized by a fibrosis of the liver. It has a multiple etiology and a correspondingly variable clinical pieture. It also varies according to its stage both

anatomically and clinically.

The duration of the disease from its incipiency to its finale is difficult to determine. As the majority of the cases show definite signs of eirrhosis in the late forties, and because the etiologic factors that are strongly suspected of producing this disease-alcohol and lues—usually start their effect on the system in the early twenties, one can feel that the disease may run twenty to thirty years. This is borne out by the fact that autopsies on subjects dying from other causes, and subjects operated on for other conditions have shown cirrhotic livers without any symptoms of cirrhosis being present. There are, however, numerous cases reported that have run their course in less than a year.

The progressiveness of cirrhosis is quite apparent by the steady downhill course it takes once the diagnosis is made. That it is progressive throughout its whole course is generally accepted today. Its rate of progress varies with the etiologic factor, with the age of the patient, and because of some unknown or "accidental factors."

Moon¹ has shown from a pathological study that the condition is progressive, but that its rate of progress is not uniform. From an examination of the specimens he was able to detect periods of very active progress and periods of lateney. On checking up with the clinical history he found that the younger the patient the more rapid the progress of the cirrhosis, and in patients over

fifty years of age there was comparatively more healing and apparently a milder and slower advance. It was evident to him that many cases had considerable periods of latency with possible improvement alternating with periods of prog-These periods paralleled the clinical manifestations, being definitely more active when ascites and haemorrhage were present. Snell2 from a clinical study of cirrhosis, came to practically the same conclusions. Also because the diuretics became less and less effective after each course until they finally ceased to act he felt "that the natural course of portal cirrhosis is downward."

Hepatic cirrhosis has a very bad reputation. The death rate may be influenced slightly with the etiology although in the most favorable group it is still high. The prognosis is grave at any stage and it is certain that cirrhosis cannot be cured anatomically. The high mortality of the group studied by Snell gave him startling evidence of the gravity of the situation, even in the early stages. Rolleston3 in 1929 thought the prognosis was far from cheerful and that in chil-

dren it was especially grave.

There is a marked difference between the early and late stages of cirrhosis. The early stage is silent. As no symptoms interfere with his accustomed life, the subject is ignorant of the fact that a disease process is affecting his liver. This unknown period may extend from a month to perhaps thirty years. In the words of Mills4 "the process is so insidious, the damage so gradual, the compensation so perfect" that the greater part of the liver is destroyed before the silence is broken with the familiar clinical signs of cirrhosis. It seems remarkable that such an important vari-functioned organ as the liver can be

^{*} Read before the Midtown Clinical Society, on December 19, 1932.

contracted at times to one-fifth of its size and ca-

pacity without the slightest murmur

The early stage is termed the latent or preascitic From the well-known progressiveness of the disease during the early stage the term latent is misapplied. This name should be reserved for the truly latent periods which are known to occur and the stage should be called the early or preascitic.

The late stage is called the active or ascitic. It usually comes on as a great surprise to the patient. Some precipitating factor can be recognized in most cases and the change appears quite.

quickly as a rule

The commoner symptoms of cirrhosis occur in the second or late stage of the disease. They are aseites, haemmorhage from an esophageal varix, and jaundice. The ascites is by far the commonest, best known and most prognostic symptom, the esophageal haemmorrhage much less common, while jaundice found largely in the bihary type, is of rare occurrence, and when it occurs in other forms, is usually only transient.

The ascites then is the outstanding symptom of cirrhosis and is the symptom by which the vast majority of cases are diagnosed. It is a visible and conspicuous symptom being recognized by the ancients who even at that time associated it with disease of the liver. To the clinician cirrhosis usually implies ascites The difficulties of recognizing eirrhosis of the liver before decompensation occurs have been so great that it is customary to make the diagnosis on the ascites Although the disease may be suspected in the alcoholic, it is difficult to be certain of the diagnosis until the abdominal fluid is evident According to Rolleston,8 ascites occurs in the vast majority of eases that run their course In those cases then that are diagnosed in the early stage one can sooner or later expect ascites providing some other disease does not end life

The rate of development and the rate of recurrence of ascites has a prognostic value. A slowly appearing ascites which fills up gradually after a tapping gives much more hope than one that appears and fills up rapidly

Ascites is a grave symptom of eirrhosis. It is a terminal symptom. Its occurrence, according to Rolleston^a has always spelled the doom of the patient. In 1929 he did not believe that one could look for a recovery once ascites had appeared. He felt that with its onset death from toxemia and coma was prone to follow. Chapman,^b Snell and Rowndtree regard ascites as a critical manifestation and have accepted it as a definite evidence of decompensation of the portal circulation. They furthermore say that the prognosis in decompensated cirrhosis is extremely grave.

Treatment has had little or no effect on the course and outcome of the disease. The authors

of twenty-five to fifty years ago were very pessimistic about the treatment once ascites had oc eurred Hale White' did not accept the diagnosis in cases reported as cures by earlier writers Hawkins' in 1908 said "any such improvement in which the term recovery can be applied is extremely rare, and the possibility of an erroneous diagnosis at onec crops up in such cases recorded case, however, in which the diagnosis was confirmed by the supervention on separate oceasions of mental symptoms and of peripheral neuritis, both elearly of alcoholic origin, the patient was in good health after repeated tappings, the first of which was performed some six years before by Bristrowe And in another instance the patient was in good health after fourteen tap pings-the first of which was more than three years before A striking example is afforded by the case of a patient who died of contracted granular kidneys and pericarditis in St. Thomas' Hospital Twelve years before he had been under the care of Murchison in the same hospital for alcoholic cirrhosis and ascites From that date the patient, who had previously drunk freely became a tectotaler and during those twelve years had been in fair health. Autopsy showed atrophic cirrhosis of the liver"

Bettman* in Forchemer's System of Medicine in 1916 says that it is certain that well-established cirrhosis cannot be cirred anatomically, nevertheless cases are recorded in which apparent cirrhosis with ascites has been followed by actual recovery for many years

For considerable time it has been held by many students of the problem that no treatment was of avail and even tapping was hardly worth while as patients frequently did not live long enough for the second tap, except in cases complicated by chronic peritoritis

As was pointed out by Snell later observers have been somewhat more optimistic. All the literature up to 1928 gave two to five months as the average duration of life after the appearance of aseites. Although eighty-four of Snell's series of one hundred twelve cases were dead at the time the average duration of life was sixteen months after the appearance of ascites. And the twenty-five patients that were then alive had averaged thirty one and three-fourths months after the decompensation.

To-day many clinicians put eighteen months to two years for the average patient to hie after he has developed aseites. It is generally accepted that an oceasional case may subside and live over a period of years. Some cures have been spon tancous and some have followed practically each and every treatment used in cirrhosis with aseites

Too much optimism must not be indulged in for as is pointed out by McIndoe^o there comes a time when not even the palliative measures suffice and the patient succumbs to one or another of the many complications of which they are especially susceptible. They pass by the haemmorhage and ascites and succumb to hepatic insufficiency. Whether or not their cases were cured, Chapman et al left open to discussion. Comfort¹⁰ and Snell brought out the point that there are no specific remedies for hepatic insufficiency and that the natural compensatory processes which accompany chronic hepatic disease are themselves a menace to the person affected. Chapman felt that in most cases treatment can only be directed to the removal of the ascites, a treatment symptomatic at best and which had little if any effect on the varied course of the disease and one that has been criticized by the older writers.

In treating hepatic cirrhosis the first move is to eliminate the etiological factor. This is not always possible. Actually, it is rarely possible. In Chapman's series half the patients gave histories of two or more etiological factors. Alcohol can be accepted as a factor in cirrhosis, but it probably plays an indirect part. Many chronic alcoholics never develop the disease, yet it is not uncommon in abstainers. Nevertheless an alcoholic history is common in cirrhosis and therefore alcohol should be interdicted. That the stopping of alcohol is of value is shown in the cases which are not infrequently reported in which a man who has begun to show signs of cirrhosis stops drinking—gets well, and stays well.

Lues, a well accepted cause of cirrhosis, should be given the approved treatment. Where it can be shown to be the sole factor in the disease, the prognosis becomes brighter. Many clinicians believe that this is the only curable form of cirrhosis. In Snell's series the patients that were alive ten and twelve years after the beginning of ascites were luetic. Luetic cirrhosis takes on two forms, a gumma or, the usual cicatrices and fibrosis. The gumma which is the most characteristic form of chronic syphilis is curable by treatment while the fibrosis is quite unyielding.

Potassium iodide has been used routinely in cirrhosis for many years. It has no effect on the fibrosis but if by chance a gumma is present in the liver the patient will be helped and may even be cured. Likewise the removal of seasonings from the food is an empirical procedure without visible improvement.

When the cirrhosis can be traced to some biliary obstruction surgical intervention is indicated and is usually followed with good results.

All medical treatment of hepatic cirrhosis to date, outside of the aforementioned prophylactic treatment, has been limited to the relief of the ascites. This relief is entirely a symptomatic treatment, and incidently the treatment of a late symptom. There has been no attack on the disease itself so it progresses on at its accustomed rate irrespective of the type of therapy now known.

The surgical treatment of ascites can be divided into major and minor procedures. The major operations may be passed over briefly because of the small number of favorable results in such a highly fatal procedure, and because even in the end they only relieve the ascites and in no way stop the disease. Yet an occasional recovery is reported for each of the operations, and so some consideration must be given to this therapy.

The minor surgical operation in ascites, paracentesis, has been the most popular from the earliest history of the disease up to today. It outranks all other surgical and medical therapy. It is a simple, harmless, procedure which gives immediate relief to the patient. In the last part of the past century some eminent men taught that tapping was a harmful act. Today the consensus of opinion is that tapping has no effect one way or the other on the duration of the disease but is a great relief to the patient and thereby should be done when the patient is suffering from pressure symptoms.

Patients may require tapping in severe cases as frequently as once every other day. A large number average about a week apart; while the milder cases only need paracentesis every six to seven weeks. As a rule, as the case goes on, the operations become closer and closer. There may be as many as fifty tappings in some cases; in fact Barker¹¹ quotes a case that had recovered from the ascites after the fiftieth paracentesis.

The medical treatment of ascites, purges and diuretics have been used from the earliest of times with the same poor results. The strain on the patient was never worth the small response.

Several years ago however, a new element was introduced which, in connection with diuretics, made a marked progress in the medical treatment This was the organic mercury comof ascites. pound generally known under the trade names of Merbaphen and Salyrgan. According to Chapman, et al, eighty per cent of the cases showed some response, a fair percentage showed considerable results, while about twenty-five per cent showed brilliant results . . . one case having had five years relief from the ascites. They felt that it was successful in fifty per cent of the cases as far as immediate results were concerned. They did not believe that life had been prolonged thereby and incidently that the removal of the ascites of itself was not noteworthy in checking the progress of the disease.

The treatment has considerable limitations. Old debilitated patients; those with kidney involvement, jaundice and G-I bleeding; and those seen late in the disease will probably be injured by it. Indiscriminate use may bring on retention of urea and acidosis.

Chapman thought that the response to treatment may be satisfactory to a degree permitting the patient to be dismissed from the hospital, re-

lieved of the discomforts of his disease, and able to carry on his business for a varying time before there is another break in the compensation of the portal circulation. With careful treatment even the second or third break in compensation may be passed successfully and the interval of good health be prolonged.

At the present time dietetic measures are becoming more popular as adjuncts to the treatment of liver disease and we are becoming more acquainted with the high carbohydrate low fat diet

in such cases.

The authors of this paper felt that any rational effort made to reduce the number of tappings, or better to reduce the transudation of fluid in the abdomen, was a step in the right direction and a justifiable therapeutic aim.

We were especially fortunate to have several cases of hepatic cirrhosis with ascites under our care at the City Hospital that sought permanent hospitalization and therefore lent themselves to

study over a protracted time.

We were impressed with the value of the high carbohydrate diet in diseases of the liver12, 13, 14, 15, 16, 17, 18, 10, 20 and also with the ability of insulin to raise the hepatic glycogen,21, 22, 23, 24, 25 apparently so important in regeneration and detoxification, that we put these cases on the high carbohydrate diet and as much insulin as they could take comfortably.

We present the following case reports of hepatic cirrhosis with ascites that were markedly

helped by insulin.

Case History No. 1. Thomas L., 47, a stationary engineer and a drinker for years was admitted to Bellevue December 20th, 1927, because of a distressing ascites. Here he was discovered to be a diabetic and was put on 20 units of insulin a day and a low carbohydrate diet. He was balanced in a week and on the tenth day was tapped of twelve quarts of abdominal fluid. Up to the time of leaving Bellevse, March 1st, 1928, he continued with twenty units of insulin and a low carbohydrate diet. He followed the Bellevse regimen while at home until August 28th, 1928, when he entered the City Hostital pital. At that time there was no evidence of acites nor had there been since his first tapping at Bellevue. For the last five years he has been consistently on twenty units of insulin and a diet of C. 150, P. 100, F. 150.

Outside of the diabetic condition all laboratory data

have been negative.

An examination on February 15th, 1933, showed a well nourished active man with telangiectic veins in the nose but with no abdominal veins visible. The abdomen failed to show any fluid, and the liver and spleen appeared normal in size.

Comment: Here alcohol stands out as a definite etiological factor with diabetes as a secondary agent. We can justifiably assume from the history that his liver was in the late part of the preascitic stage before he became diabetic. ordinarily means a small liver and a reduced liver glycogen. As diabetes is a disease that when untreated lowers the glycogen content of the liver we would expect a very low liver glycogen in this case at the time his ascites appeared. We might further assume that the insulin raised the glycogen of his liver to the amount present before the diabetes occurred.

Perhaps we can explain the occurrence of ascites with the lowering of the glycogen of the liver by the diabetes and the disappearance of the ascites with the increase of glycogen by the in-

Whether the insulin by increasing the glycogen of the cells produced more regeneration than would occur without it cannot be said but such improvement as he made cannot be attributed to a high carbohydrate diet as he never went above 150 grams a day.

Case History No. 2. Louis K., 60, uphoisterer, admitted to the City Hospital, July 8, 1931, with the diagnosis of cirrhosis of the liver. His chief complaint was painless swelling of the abdomen and edema of the ankles. He said he first noticed the ascites in January, 1931, and since that time had been tapped once a month. Denied venereal disease, but admitted a moderate amount of alcohol. An examination showed the patient com-fortable in bed without dypnsea or other complaints, Heart and lungs were negative. There was no evidence of lues. His abdomen showed ascites and there was some edema of the ankles.

His initial treatment was restriction of fluids and salts and various diuretics. On November 19th he was put on a high carbohydrate diet. On December 1st five units of insulin were added before meals with a weighted diet

of 400 grams of carbohydrate.

A progress note dated December 22nd says as follows: "Patient has had a tap once a month for the last yearsometimes at intervals of three and at times six weeks. The last tap was twelve days ago. Feels no fluid in abdomen which is unusual for this number of days. Ordinarily swelling comes back two or three days after the tap. Weight has not increased since he was put on the high carbohydrate and insulin. Feels better since he is on the new regimen.

His insulin was dropped from February 6th when he was given 15 units before each meal. The insulin was

dropped for good on May 4, 1932. He asked for a discharge in August because he said he felt too good to be in a hospital. He left the hospital on August 16, 1932, twenty-eight weeks or 196 days after his last tap. His discharge note reads "No ascites. Greatly improved. Diagnosis: Cirrhosis of the liver."

Dates of tapping at the City Hospital: 8-31, 13,000 c.c. 9-4-31, 20,000 c.c.: 9-15-31, 12,000 c.c.: 10-31, 5,000 c.c. 10-16-31, 6,000 c.c. 10-27-31, 18,000 c.c.: 11-9-31, 12,500 c.c. 12-9-31, 16,000 c.c.: 2-3-31, 6,000 c.c.

All laboratory reports were negative. A recent examination February 15, 1933, shows him greatly improved and considerably fleshed up. There has been no accumulation of fluid in the abdomen and hence no tap since he left the hospital.

Comment: This case exemplifies the dictum that cirrhosis developing in elderly people is mild. The fact that there is no visible etiological factor makes one suspicious of an endogenous toxin. And because he responded so quickly to the treatment one feels that the toxin must have been

Case History No. 3. Edward R., 54 years of age on admission to Bellevue on January 13, 1931. His chief complaint was ascites of eight weeks' duration that appeared suddenly. He gave a marked alcoholic history, but denied venereal disease. While in Bellevue, about

thirty weeks, he was tapped 16 times.

He was admitted to the City Hospital on August 17, 1931. He showed telangieetasis of the nose and eheeks. There were enlarged veins on the abdomen. He had no jaundiee, no history of haemorrhage, and admitted to a good appetite. He had no signs of lues and his heart was apparently normal. During the first week in the City Hospital he was tapped three times. Following that he averaged eight days between tappings for a while.

On December 1st he was started on 5 units of insulin before each meal and 150 grams of earbohydrate were added to the daily ward diet. On the 13th of Deeember he was admitted to the metabolie ward for further study. On the 12th his insulin was raised to 10 units before each meal with a weighed diet of at least 400 grams of earbohydrates. It was very hard to get him to eat his full quota of starehy foods as he complained that he would lose strength and die if he did not get more meat and less carbohydrates. He said that he never ate potatoes or sweets as far back as he could remember, making meat and fish the main part of each meal.

A note on the 16th of December said that he was last tapped on the 11th and that the fluid was not eoming back as fast as usual and that he felt better all over. This tap ineidently was the 37th to date and the 19th

since August 17th.

His insulin was discontinued from May 4th to July 11, 1932. He was then put back on his former dose of 15 units before meals. Up to June 14th the taps were getting further apart. He had six taps so far in the metabolic ward during the 22 weeks. This averages about 25 days between taps rather than the eight-day schedule before starting the insulin. Beginning on the 14th day of June he went 14 weeks without a tap. Unfortunately a poor tap was done on the 14th of September and only 3,000 e.e. of fluid were removed instead of the usual 5,000 to 6,000 e.e. leaving what appeared to be 3,000 e.e. still within the abdomen.

Note on October 26th, says he feels very strong and is anxious for his discharge so he ean resume work.

All laboratory reports were normal. Recent examination February 15, 1933, shows condition excellent, no fluid, 168 days since the last tapping.

Comment: Here is a definite alcoholic history for thirty years. The other possible factor, lues, can be ruled out. It is of great interest, however, to analyze his diet. Here is a man of fifty-four years that all his life lived on excessively high protein with fats a close second. He disliked carbohydrates and went out of his way to avoid them. During his stay in the hospital there was one continuous complaint about the high corbohydrate in the diet. No matter how he was lectured to or scolded worked every ruse to get a high protein diet. The same pressure has to be brought to bear now while he is a clinic patient. Knowing the man we are skeptical about his diet while at home.

Case History No. 4. George H. A Japanese servant -admitted to the City Hospital, July 26, 1931, with the diagnosis of eirrhosis of the liver, probably luetie. He gave a history of a venereal chancre contracted in 1926, a recent positive Wassermann and three injections of arsphenamine.\ He admitted to a moderate use of alcohol for over twelve years. He denied any rheumatic history. On admission he showed ascites 4 plus with edema of the ankles. He left the hospital in the beginning of October. During this stay he received 12 injections of arsenie and 12 injections of bismuth. He was not tapped during this period and left the hospital somewhat improved. He was readmitted on November 5, 1931, with the straight diagnosis of luctic eirrhosis of the liver. He then showed a marked abdominal distention with some swelling of the feet. He was immediately put on 15 minims of K.I. t.i.d. and a teaspoonful of mixed treatment t.i.d.

Tapping was begun on December 2, 1931. On February 3rd he was ordered a high earbohydrate low fat diet. On the twentieth five units of insulin were started before each meal. Fluids and salt were restricted. The insulin was discontinued on March 12th. On March 22nd ten units of insulin were ordered for the day. This was eontinued until July 17, 1932. The insulin was started again on the 28th when 10 units were given before meals. On August 16th twenty-five units were given before breakfast and 25 units were given before supper.

There were 15 taps done from December 2, 1931.

The number of days between taps were as follows: 15, 20, 15, 14 (high earbohydrate diet started, followed by small doses of insulin), 23, 16, 11 (increase in insulin) 18, 20, 31, 30, 34 (further increase in the insulin) 65, 84.

Because the insulin gave him shocks now and then he became very uncooperative and would refuse meal after meal so he would not have to take the insulin. After the tap following the 84 day span he was noticeably emaciated and a very rapid return of the fluid occurred.

The majority of a number of Wassermanns taken

during his stay showed a faintly positive reaction.

Otherwise all laboratory data were negative.

A recent examination—February 15, 1933, shows him emaciated with intervals of about two weeks between taps.

Comment: This is our least responsive case. We consider it a definite luetic cirrhosis. feel that the arsenic and bismuth were detrimental to him. We believe that they added more load for the disabled liver and were in a large part the cause of the decompensation. Perhaps the alcohol played a part.

It would appear that definite fibrosis rather than a gumma is present in his liver as he has had a number of courses of potassium iodide in

large doses without any effect.

He is the only case that showed shocks from the insulin. At the start he was able to handle as much insulin as any non-diabetic but as time went on he got more and more shocks even when the insulin was reduced.

Case History No. 5. Wilfred A., earpenter, 36—was admitted to the City Hospital, service of Dr. Siglar on January 9, 1932, as a Bellevue transfer. He stated that early in December, 1931, he began to lose his appetite and get distress of the state of the He and get distress after even small amounts of food. He had no nausea or vomiting at that time. About the 15th of December became jaundieed. He thereupon entered Bellevue where he was given gall-bladder dye by mouth. On January 1st he began to vomit everything and lost about twenty nounds by the middle of Tongary. about twenty pounds by the middle of January.

The Bellevue transfer diagnosis was lead poisoning Entrance examination to City Hospital showed a middle aged, well built man with marked jaundice, mental dullness and edema of the ankles. The heart and lungs were normal. The pulse was 44 and the blood-pressure was 116/56. There was no ascites or distention. There was no visible masses or rigidity on palpation. Pressure over the gall-bladder region, however, elicited nausea and pain. The liver edge was not felt nor was the spleen palpable. At no time was there diarrhea or the spleen palpable. At no time was there diarrhea or

bloody stools.
On January 11th the blood urea was 20 mgs., the fasting blood sugar 100 mgs., the leteric index 200, the Van den Berg direct delayed reaction was positive and the bilirubin was 125 units. On the 12th of January the stool was negative for blood with benzadine, the E K G was negative, and a Wassermann was negative

Because of excessive vonting he was given by vein at 11 A M and again at 4 P M 300 e c of 10% glucose and 15 units of insulin. On January 14th the interior mdex was 150, the Van den Berg direct was positive and the indirect positive, and the blirtubin was 13.0 material. units An a-ray on this date showed the chest and heart negative There was no sign of abnormalities in the abdomen and no metastatic neoplasms found in the spine, pelvis or upper ends of the femora. This date showed the patient very restless with twitching clonic movements and an increase of the jaundice A diagnosis was then made of Acute Hepatitis (Sub acute Yellow Atrophy) with early cholemia

On January 18th he was better but with the jaundice still present. An intravenous injection of 400 c.c. of 10% glucose was given by vein on the 27th On the 2nd a note says that the patient was much better and the jaundiec improved but a cirrhosis should be watched On the fifth there was evidence of ascites and edema of the scrotum and legs. The teteric index was 100 and the NPN 30 mgs. The Van den Berg direct was immediate and the indirect was positive. The serum albumen was 43% and the serum globulin was 26%

A paracentesis was done on February 13th and 3,300 ce of a cloudy green fluid were removed. At this point the patient was given a high carbohydrate diet and five units of insulin BID. The insulin was continued until the 22nd when it was discontinued until the 28th when it was resumed and given through March 12th. The next paracentesis was done on the 8th of March when one and one half quarts of fluid were removed

The next and last tapping occurred on the 25th of March when 3500 ec were removed
On March 28th the icteric index was 35, the Van den Berg direct was immediate and the indirect was posi-tive. On April 2nd the icteric index was 20 and on May 25th the icteric index was 10 and both the Van den Berg reactions were negative

He was discharged on May 26, 1932, with a note saying that there were no complaints except tenderness about the liver and a continuous itch over the entire body

Comment We have here a case that fits into the class of cirrhosis that runs its course in a

The etiology is not clear though short time Bellevue considered lead to be at the bottom of it How much a part the dye played is a question, but it may have added to the insult. The entrance diagnosis of hepatitis or sub-acute vellow atrophy with cholemia is justified from the his-The use of intravenous glucose and insulm, although of limited amounts, seems to have turned the tide

The patient improved as the jaundice did Decompensation, however, set in about six weeks after the initial symptoms of disease Dr Lisa, pathologist at the City Hospital, is satisfied that cirrhosis commonly follows sub-acute vellow atrophy of the liver and it would seem to have occurred in this case

SUMMARY

These five cases of hepatic cirrhosis show the benefits of insulin High carbohydrate diet was employed when possible-which was in four In the first case the patient, because of hus diabetes, was carried from the start on the low carbohydrate dict and through his own choice remains on it. Yet this case has passed five years without showing a sign of a return of the ascites

We do not offer this treatment as a cure of hepatic cirrhosis nor do we ofter it as a permanent cure of the ascites, because we realize for that, longer periods of observation and post-mortem studies must be made. What we do believe, however, is that it will re-establish compensation in some cases and lower the transudation in others so that the intervals between tapping may be extended From the work of Moon and Snell we conclude that it has brought about a check in the progression of the disease as much at times to be called a latency

PEDIATRIC DIAGNOSIS OF ORTHOPEDIC CONDITIONS

By ARMITAGE WHITMAN, M.D., NEW YORK, N. Y.

Read at the Pediatric Conference of the Fifth Avenue Hospital in December, 1932.

TAM constantly amused, and perhaps even more constantly irritated by the attitude of patients who resort to specialists for treatment. A man with whom I roomed in college once regaled me with the horrors of his son's broken arm and bemoaned the fact that they knew of no one but a general surgeon to whom they might take him. A patient with curvature of the spine will never suspect that a spine doctor treats feet, nor will a patient with infantile paralysis recommend his specialist for Pott's disease. short, the borderlines of specialization have become so sharply defined that doctors themselves are not quite sure where one specialty leaves off and another begins. Needless to say their uncertainty has communicated itself to their patients, who select their own specialists, osteopaths, chiro-practors or what have you. You are familiar with the results, both to the patients and the medical profession. What this country needs, next to a decent political party, is doctors who are doctors and can see their patients as doctors first and specialists afterward.

These comments were aroused by the fact that when the subject "Early Deformities in Children" was suggested, there was some discussion as to whether such a paper should be presented to an audience of obstetricians or pediatricians. No definite decision was reached as to when a baby was weaned, so to speak, from the obstetrician. It was decided, however, that it was reasonable to suppose that the obstetrician's attention might possibly be slightly distracted by the mother in the case, whereas the pediatrician's professional gaze would, and should, be focussed exclusively upon the child.

I do not propose to enter into an exhaustive catalogue of congenital deformities and malformations. Mothers may usually be relied upon to notice that their child has six fingers or a spina bifida, although one encounters such extraordinary oversights that sometimes one doubts that anyone ever notices anything. I remember a twelve-year-old boy being brought to the hospital because the mother the day before had noticed that he could not supinate his hands. been Jewish this deficiency would naturally have been noticed before. The diagnosis was congenital radio-ulnar synostosis. The family history was taken and no such deformity had ever been heard of on either side of the family. The mother suffered from it herself and had never realized it until the moment of her son's examination.

I take it that everyone is in the habit of making a routine physical examination, examining every portion of the patient whether or not it seems germane to his complaint. I suggest a

few orthopedic additions to the pediatrician's routine physical examination, by which he might notice early defects which age makes it increasingly difficult to correct. I know of no art more hemmed in by superstitions and traditions than medicine. "Don't take her to a hospital, she'll die there." "You can't treat that now, the child is too young." As a matter of fact the growing child is comparable to a growing tree, and the sooner any twist or kink is recognized, the easier is it to undertake treatment and see that the child grows straight. From the orthopedic standpoint the only reason for delaying treatment has been that treatment often implied plaster of Paris, and that it was sometimes impossible to maintain plaster treatment effectively until the child was housebroken.

Beginning at the top and working down, the first member for consideration is the head. I suppose that nowadays in any case of prolonged labor or instrumental delivery the possibility of brain injury would be considered by all concerned. I do not know what the attitude of the pediatricians and neurologists is, but it would appear to me that in any such case, when the baby was either abnormally irritable or abnormally drowsy, a diagnostic lumbar puncture was justified. Whether or not, in cases in which the intracranial pressure continues high, a decompression is advisable is out of my province to say, but if it is, surely the earlier it is done the better. It would seem reasonable to suppose that at least some of the typical spastic cases that we see, as well as some of those rather loosely classed under the head of delayed cerebral development might be averted by early operative treatment. Speaking of delayed cerebral development it might be proper to say here that in badly spastic and deformed patients who can locomote, if at all, only with the most extreme difficulty, judgment as to their mental state should be deferred until their deformities have been relieved. Naturally I exclude the obvious idiots. In the doubtful cases, however, it would appear that the average patient has a given quantity of energy at his disposal, and if he has to use it all on the painfully difficult process of locomotion he has little if any left over for cerebration. I well remember a twelve-year-old colored boy, sent to me from South Carolina for operation. He was terribly deformed, completely helpless, and arrived with the local reputation of idiocy. His appearance and behavior on admission cast no doubt upon the diagnosis. I operated on him under protest really only because he had come from such a distance. As his deformities were corrected and he was enabled to walk, even with the assistance of braces and crutches, his mental improvement was nothing short of extraordinary,

and he left the hospital with an intelligence far above the average.

Harelip and cleft palate could hardly escape attention, and I think the doctrine of early surgery is governly accounted

is generally accepted. Torticollis, on the contrary, is rarely noticed until the child sits up, although occasionally the mother will complain that the baby holds its head habitually to one side. Stromeyer's theory is that the deformity is caused by partial or complete tear of the sternomastoid muscle in the course of a difficult instrumental delivery, and that as a result the muscle undergoes fibrous degeneration. It would seem more reasonable to suppose it the result of some intrauterine condition, but the etiology is unimportant. The deformity is mild at birth and might easily be overcome by systematic daily manipulations. The sternomastoid muscle draws the head toward the affected shoulder and turns the chin to the opposite side. All that is necessary, therefore, to make a diagnosis is to see that the head has an equal range of motion in all directions. After a year old, the only effective treatment is operative division, not only of the sternomastoid muscle, but of all the other contracted tissues in the neck. This is followed by immobilization in plaster of Paris in the overeorrected attitude, followed by systematic manipulation. Neglected eases of course lead to severe secondary deformities; hemiatrophy of the face, and kyphososcoliosis of the spine.

Congenital dislocation of the shoulder is comparatively rare. A condition for which it is frequently mistaken is Erbs' palsy, or obstetrical paralysis. This results from injury to the cords of the brachial plexus, most frequently the fifth and sixth. The common form of paralysis is thus of the upper arm type, the affected muscles being the deltoid, the supra- and infraspinatus, biceps, coracobrachialis, and supinators of the forearm. The common deformity, resulting eventually from unopposed muscular action is that the head of the humerus is gradually suhluxated posteriorly, so that the arm is abducted, flexed forward, rotated inward, and the forearm pronated.

The logical treatment of course is surgical repair of the injured plexus, but such treatment does not seem widely to have established itself. If the deformity is recognized and the arm placed and held continuously in the overcorrected attitude, the nerves seem, in a great majority of cases, to repair themselves. This treatment may easily be carried out by means of a wire splint, and provided it is uninterrupted the recovery is usually very satisfactory. When the injury to the plexus is more extensive as indicated by paralysis of the muscles of the land, the prognosis is much worse, and if early surgical treatment is ever to be employed it is in such cases. The majority of patients seen in hospital practice represent the later neglected cases in which the diag-

nosis has not been made. In these the unopposed action of the normal muscles may have brought about a posterior subluxation, if not actual dislocation of the head of the humerus, and open operation, division of the contracted nuscles, and reduction of the dislocation is necessitated. The degree of recovery is then usually very satisfactory, although of course the upper extremity never loses the atrophy which it incurred during the period of disuse.

Congenital scoliosis-curvature of the spineis almost never noticed until the child sits up, and the force of gravity is allowed to exert its pernicions influence. True congenital scoliosis comes from a bony malformation of the spine, such as a hemivertebra. Frequently such malformations are multiple. They may be detected by a routine careful palpation of the spine, and if found early and treated by prolonged recumbency upon a convex stretcher frame, supplemented later by apparatus they may be arrested. If progressive, in spite of treatment, the logical remedy for such a deformity is a fusion operation. Some enthusiasts, striking at the root of the matter, are recommending removal of the offending vertebræ in toto. While such surgical feats are possible, their advisability seems to me improbable. what a surgeon can do, and what he should do, is a wide margin requiring the exercise of surgical judgment.

Having inspected the head, neek, upper extremities and spine we come now to the most important subject, congenital dislocation of the hip. This is a condition in which, from the orthopedie standpoint, the results are notoriously unsatisfactory. This deformity has been a cinder in the American orthopedic eye since Dr. Lorenz came to this country thirty-two years ago to treat Lolita Armour. Dr. Lorenz is a Viennese surgeon who was long ago forced to give up surgery because his skin would not stand the carbolic spray under which surgeons at that time operated. He thus became interested in seeing what could be done without the knife, and succeeded in reducing a number of congenital dislocations of the hip. He published his method, which was widely employed in this country, and was tried unsuccessfully upon his famous patient by two surgeons. As a last resort Dr. Lorenz, as the originator of the method, was imported, and his effort—a fact which has escaped public attention -was also unsuccessful,

The incident was useful in focussing attention upon the deformity, and since then, while orthopedic ingenuity has been devising more successful methods of treatment, inclining more and more toward various open operations, the truly important factor in treatment is early diagnosis. As a matter of fact, Dr. Lorenz is somewhat to blame for this, as he announced that he did not care to treat children under four years of age.

This was because he used plaster of Paris as a fixation apparatus and there was no use in applying plaster until the child was housebroken. That was logical enough, but at the same time it removed a great responsibility from the pediatricians, because by the time the child began to walk anybody could notice that it limped.

I now propose to place that responsibility back upon their broad and capable shoulders. Professor Vittorio Putti, of Bologna, Italy, lives in a district in which, for some reason or other, the deformity is extremely common. He has succeeded in educating the mothers in that district to look for, and find the deformity, and his results, when treatment by a wire splint is begun early and rigorously maintained, far surpass those obtained anywhere else by any other method.

Inspection and measurement will show shortening in unilateral cases. In bilateral cases it will be seen that the trochanters are elevated and The head of the bone cannot be felt prominent. beneath the femoral artery. If the hip be fully flexed and adducted the head and neck may often be felt displaced posteriorly, rotating beneath the gluteal muscles. Either pulling or pushing on the limb as a whole will disclose the abnormal mobility of the displaced head. When in doubt an x-ray will make the diagnosis, although I resent the degree to which the x-ray has displaced the evidence of our senses. We are rapidly approaching a time when a patient cannot have a disability unless it shows in the x-ray. I digress, excusably, I think, to mention the number of neglected joint conditions that I see, neglected because an x-ray was taken at the time of the injury and the x-ray showed nothing. As respects orthopedic conditions the x-ray shows very little but bone, which perhaps explains the homeopathy of its appeal. Injuries to cartilage, ligaments, tendons and muscles do not show in the x-ray, and if neglected are often far more serious in their late effects than is a simple fracture.

It is Putti's practice to reduce such early cases without an anaesthetic, and maintain the reduction by some form of wire splint which may be removed for cleansing, while the mother holds the limb religiously in the position of reduction. Unsatisfactory results are almost always caused by failure of development of the roof of the ace-When mutual pressure between the head of the femur and the acetabulum is established early it seems of the greatest importance in stimulating development of the roof of the hip joint. The excellence of the prognosis, therefore, varies inversely with the age, and I can think of no disability in which the mutual assistance of the pediatrician and the orthopedic surgeon would be more truly mutual and would bear better fruit.

Congenital contractions of the hips and knees occur, but are rare, are obvious and easily de-

tected. As a rule they may be corrected by simple daily manipulation. I may here interject that there are a great number of conditions that might be cured by simple daily manipulation—provided the parents could be trusted to carry them out. I am continually astonished when I review the scale, starting with chiropractors at the bottom and highly trained gymnasts and physical educators at the top, and think of the time and money that are spent on such treatment that could just as well be carried out at home. Indeed, there are times when one wonders, not whether honesty pays, because of course it doesn't, but whether honesty works. Is not an element of charlatanism necessary to make a patient follow simple, daily routine treatment? I suppose we should not wonder when we recall how long it took us to establish brushing of our own teeth.

Bowlegs and knock knees are subjects which cause much heartburning between pediatricians and orthopedic surgeons. Of course, they are usually caused by a greater or less degree of rickets, and as the pediatrician is supposed to cure rickets before it even appears he resents the diagnosis as casting doubts upon his constitutional treatment. To salve his feelings, therefore, I wish to say that his treatment of rickets has been so successful that as a staple of orthopedic practice bowlegs and knock knees have been almost cut Twenty years ago at the Hospital for the Ruptured and Crippled an operative morning never passed without two or three such cases, and the brace shop was always busy making braces for the milder ones. Last year on my service two such operations were performed. I can also testify that such deformities occur in the absence. of rickets and in most robust and healthy children, so that the pediatrician need not feel slighted by the diagnosis.

The orthopedic surgeon, on the other hand, has his feelings occasionally lacerated by advanced cases that were taken by anxious patients' parents to the doctor, only to have their fears poohpoohed with the phrase, "Oh, the child will grow out of it." The fatal danger of that phrase is that it is so often true. The trouble lies in the tact that I, at least, know of no way of separating those that will from those that won't. There can be no harm in taking tracings of the child's legs and instructing the parents in daily bending of the limbs, which simple measures are in most cases, provided they are faithfully carried out, all that are necessary. In case they are not successful advanced cases may be most satisfactorily treated by operation. In expert hands the operation is simple, accurate and painless. The reason that I venture to emphasize the expert hands is lest some of you may have painful memories of the girl in Chicago who recently lost both legs as the result of inexpert ones. The operation is followed by eight weeks in plaster, during which time the child is encouraged to stand about, and walk with crutches. The plaster is then removed and braces substituted, which are worn for a period depending on the rapidity of bone repair in the particular case. The alternative is corrective braces worn as a rule for over two years. The result can never be predicted with certainty, so that the operative treatment of severe cases seems to me, though involving the shedding of blood, far more merciful.

We started the orthopedic examination of the child at its head, and we have now reached its feet. We may regard the feet as one of the staple sources for low humor, or, as I prefer to, as the foundation of the human body. Certainly I should prefer a good head to good feet, but no one can deny that the foundation is of prime importance to any structure, and that it deserves constant supervision.

I think this subject of such importance that perhaps I may be excused for a brief historical digression. Foot troubles are vulgar. They are vulgar because they are associated with the "vulgus" or mob, whereas the term for aristocrat in Latin was "equester" and in French "chevalier"in other words, a man who rode a horse. Consequently his feet were functionally of no importance, and could be used merely as an ornamental finish to a gentleman or lady. The shape of the shoe had no relation to that of the foot, and was dietated solely by fashion. I recommend a visit to the exhibit of arms and armor at the Metropolitan Museum.

I recently encountered a perfect example of the historical attitude. A patient came to my office, a man I knew socially. With an extremely deprecatory smile he enquired if I ever did anything for the feet, because he had a big toe that was giving him hell. He had injured it in youth and had the equivalent of a baseball finger. Suffering from such an injury to the finger one avoids using the finger, which eventually gets well. Such an injury to the toe gets no rest, and eventually gets worse. The man was thirty-five years old, a stockbroker. He was unable to stand on the floor of the Exchange. He could not play squash, tennis or golf. When he returned home in the afternoon he was forced to take a taxi from the elevated, two blocks from his home. Such effects produced by a decompensated heart would bring tears. Produced by a toe they inexplicably became funny.

I suppose I am in radical disagreement with almost everyone here on the subject of treating growing children's fect and perhaps this is the best opportunity I shall ever have to explain such

an extraordinary difference of intelligent opinion. The feet may be used in two ways-in the active and in the passive attitudes. In the active attitude the feet are held parallel, straight allead, under the leg. The whole foot, not the heel, is brought to the ground at once. The gait is soft, stealthy and catlike. The active attitude is attained by constant practice, and maintained by

muscular activity alone.

When the individual is untrained or fatigued, he lapses into the passive attitude. He collapses upon his ligaments and bones. His feet are abducted, toes turned out, feet held wide apart so that the body weight falls upon their structually weak inner border. He takes long steps and bangs upon his heels. He walks like a sailor on a rolling deck. He emulates the staggering infant or the inebriated adult.

I wish that all bad habits could be cured by conversation. I believe firmly that the treatment of the feet begins in the head, and that if I could persuade a child, his parents, his associates, his teachers and his doctors to take as much intelligent interest in his feet as a child prodigy does in his violin, shoes or any apparatus would never

be necessary. But I cannot do it.

Conversely I have never been able to see how a bad habit is to be cured by persistence in the bad habit. I have no idea of the number of children brought shambling in upon weak feet and knock knees whose parents, when reproached, say mournfully, "I noticed that years ago, and Dr. Blank said, 'Oh, never mind. Take off his shoes and let him run barefoot and he'll grow out of it.'"

This provides a pretty picture of Junior gamboling in the dew, drinking in the sunshine through every pore of his bare feet, but how it teaches him to use them properly I don't quite see.

As a compromise between these two extremes of idealism my father long ago devised the Whitman brace, a form of apparatus the purpose of which, in the treatment of children, has been almost universally misunderstood. It is generally regarded as a rigid, painful, steel support, which does all the work for the muscles, cramps the growing structures, and upon which the child be comes indefinitely dependent. It is contemptu ously dismissed as a form of arch support, and as such, as made and applied indiscriminately by bracemakers and even shoemakers, it deserves such dismissal.

The purpose of the brace is to force the child to hold his feet straight and to hurt him if he doesn't. By keeping his feet straight it forces him to use the muscles of his legs in walking. When his muscles become fatigued the brace supports the foot, but supports it constantly in the correct attitude. The mental aspect is forever emphasized. It is pointed out that the more effective the treatment is carried out the sooner the braces can and should be discarded. I deplore the necessity for placing unyielding metal in contact with an adolescent tender sole, much as I deplore the placing of a curb bit in the tender mouth of a young horse, but I reognize the necessity for

the training of both, and feel that in the end such stern measures are the most merciful.

There is always a tendency in a paper of this sort either to affront your audience by speaking in too simple golden words or to bore it by assuming that it knows too much. I have said much that I am sure many of you knew already. I shall feel rewarded if the pediatrician's diagnostic vision now embraces a little more of structure and locomotive functions of the body.

Discussion: Frederic H. Bartlett, New York. N. Y. In regard to the substance of his paper, all that I can say is that my plan has been to let children walk barefooted, to walk barefooted in the sand, and drag the feet in the sand with a view to strengthening their ankles. If his theory is correct, I have been wrong, and he has almost, but not quite, convinced me that I have been absolutely wrong. I still feel that there is something to be said for the use of the muscles of the ankles and leg as a means of strengthening the foot and

leg. The points in his paper make me wonder if I have been correct. He presents the matter in a most convincing way, although I confess I am still to go one stage farther before I am fully convinced that his advice is entirely the correct one.

As to the future of my own handling of children, I confess I do not know whether to follow Dr. Whitman's plan, or to fear it. The coward always walks in medias res, and I daresay that I will be one of those middle-road men without the courage to take the stand.

THE ONTARIO COUNTY PLAN FOR THE MEDICAL CARE OF INDIGENTS By HOMER J. KNICKERBOCKER, M.D., GENEVA, N. Y.

From the Economics Committee of the Medical Society of the County of Ontario.

HE County of Ontario, State of New York, comprises a territory of 649 square miles. It had a population of 54,276 in 1930. There are two cities, Canandaigua with a population of 7,541, and Geneva with a population of 16.053. There are ten incorporated villages and seventeen organized townships. Each of the two cities is operated independently of the township in which it existed prior to its incorporation as a city. Both of the cities and seven of the villages are more than 40 per cent industrialized. There are 69 physicians in active practice. The County Medical Society roster contains the names of 75 members, in addition to which there are four physicians practicing within the county who are not members of the County Medical Society. Ontario County has a reputation for pioneering. The first rural public health laboratory and the first rural tuberculosis sanitarium in the state are among its achievements.

Article 2, Section 4 of the New York State

Public Welfare Law reads as follows:

"The Superintendent of the Poor, elected or appointed in each county, shall, after January 1st, 1930, be known as the County Commissioner of Public Welfare and shall have all the powers and duties of a County Commissioner of Public Welfare as defined by this chapter."

This applies exclusively to Ontario County without mentioning it. What we now know as the County System originated in the County of Ontario in 1836 and has since been in

operation. Under this plan all Public Welfare relief is chargeable to the county as a whole, and no charging back to the township or city This makes it possible to have a compact unit under which the Commissioner of Public Welfare heads the organization with deputies scattered throughout the county. The deputies do the investigating only. The Commissioner approves or disapproves the applications for assistance and issues all requisitions for medical care and hospitalization. No deputy is permitted to hospitalize a case except in emergency. There are three completely approved general hospitals within the county having a total bed capacity of upwards of 385. In addition there is a small private institution qualified to care for maternity patients, and certain types of medical, old age, and boarding cases. A Childrens' Home, a tuberculosis preventorium, a tuberculosis sanitarium, and emergency accommodations at the County Home are also maintained.

Until 1932 doctors were under contract, one in each town or city in the county. Their annual compensation ranged from \$15.00 to \$150.00, and they were supposed to provide medical care for all people receiving county aid. In some instances they never did earn their money, while in others the pay was ridiculously small for the work done, and in still others the contracting doctors dumped everything they possibly could into the hospitals and onto the service of the medical staff.

Naturally this state of affairs did not meet with the approval of the medical profession in general. After the Public Welfare Law was passed, we sought to have the county abandon the contract system and substitute therefor the privilege of free choice of physician and payment for services rendered by some form of agreement between the County Medical Society and the Commissioner of Public Welfare. All kinds of obstacles were encountered, but finally after twenty months of discussion the Medical Society accepted an agreement of its own writing, and guaranteed to the county that for the year 1932 the expense for medical care alone would be no greater than it had been for the previous year under the contract system.

The essential points of the agreement are as follows:

- 1. That the Board of Supervisors provide a lump sum appropriation for medical services to welfare cases, which remains intact until the end of the calendar year and then is prorated by the Commissioner to the various physicians presenting bills for services based on the County Medical Society Fee Bill. The County Medical Society undertakes to guarantee the validity of these bills by viseing each one before presentation to the Commissioner, Bills are presented to the Commissioner quarterly.
- 2. The custom of employing part time doctors for public welfare cases is suspended during the term of the agreement. Individual authorization is issued for each separate case accepted for medical treatment by the department.
 - 3. The types of cases covered are
 - a. Indigent poor.
- War veterans and their dependents who are accepted by the Commissioner of Public Welfare as proper charges against the Public Welfare District of Ontario County.
- c. Emergency old age cases accepted for hospital treatment but not for treatment in their homes.
- d. Children in boarding houses who are charges against the Public Welfare District of Ontario County.
- e. Public welfare cases employed on relief work projects disabled by accident sustained during such employment, but not to such accident cases in which no disability from work is sustained. This latter class falls under Workmen's Compensation Law so far as medical attendance is concerned. (Ontario County is a self insurer.)
- f. Exceptional cases whose welfare requires, may be treated by physicians in ad-

joining counties only with the approval of the Commissioner and the Committee on Medical Economics of the Medical Society. This last type of case is rare. It consists of the individual who lives near the border of the county, far removed from any physician practicing within the county and adjacent to an approved physician resident in another county, who is willing to accept the terms of the agreement.

The County Medical Society Minimum Fee Bill allows \$3.00 for a visit in a city and \$2.00 for a visit in other parts of the county. Calls between 6 and 10 P.M. are \$4.00 while those between 10 P.M. and 7 A.M. are chargeable at \$5.00 each. Office charges are \$2.00 with medicine, dressings, etc., extra. Uncomplicated obstetrical deliveries \$35.00 with \$50.00 for version or forceps. Anesthetic charges range from \$5.00 to \$25.00 according to the time spent and material used. Appendectomies and abdominal operations of similar magnitude are \$100.00. Hysterectomy, cholecystectomy, intestinal resection and stomach operations are rated at \$150.00. Hernias range from \$75.00 to \$150.00 according to conditions met. The charges for all major surgery includes a period of two weeks of postoperative care in the hospital only. Fracture cases are treated on the schedule sent out by the Committee on Medical Economics of the State Society some years ago and published in the Journal of May 1, 1931, page 555. The schedule includes dressings required for a period of three weeks following reduction. A uniform rate of \$3.50 per day for ward service in the hospitals has been agreed to. This does not include x-ray, ambulance, special dressings or medicines, nor does it include use of the operating room. Laboratory service is provided through the County Laboratory and is free to welfare patients.

Nothing in the agreement is applicable to cases arising within the county and chargeable back to any other county, nor to cases arising in any other county and chargeable back to Ontario County. Under the agreement no services are rendered to the inmates of the county jail, police stations, or the county lome. These are taken care of by individual contracts outside of the agreement with the County Medical Society.

Two emergency calls are approved providing the case is accepted later as a proper case for county welfare assistance. A public health or red eross nurse, police officer, state trooper, or welfare worker calling a physician is considered sufficient authority for the first call, with the understanding that prompt investigation will be made and if the case is accepted the first calls will be considered a valid charge against the allocated fund.

The privilege of caring for public welfare

cases under this agreement is open to every duly licensed physician and surgeon (but not to osteopaths) resident within the County of Ontario.

Neither the Commissioner, his deputies, or any one employed by or serving under his department shall in any way influence the patient in the selection of his or her medical attendant, providing that such selection be made from duly licensed physicians and surgeons resident in Ontario County who are approved by the Commissioner and the Medical Society, and are practicing within a reasonable distance from the patient's residence. The physician treating the case shall have the privilege of selecting any one of the three approved hospitals within the county in which to treat the A uniform hospital rate has been established. Patients are not encouraged to request treatment in hospitals removed from the district in which they reside, but they may be permitted to do so for special reasons. Separate written authorization for hospital care is issued by the Commissioner only on the request of the physician in charge of the case. All authorizations for medical and hospital service is limited to two months, after which it must be renewed.

Physicians treating public welfare cases agree to grant to the Commissioner all the consideration ordinarily granted to parents, guardians, and responsible relatives the same as they do with their private cases. They also agree to give the public welfare case the same consideration in treatment that they do their private cases.

Any grievance which may arise is subject to arbitration before a committee of the County Medical Society. The Medical Economics Committee is charged with the responsibility of making investigations, acting as mediator, and if indicated citing the case for arbitration.

During 1932 the plan worked satisfactorily. Every member of the County Medical Society cooperated. Some thought the red tape too much and presented no bills. Two of the four practitioners of the county, not members of the County Society, came in on the plan. Many bills presented by rural practitioners had to be marked up to meet the requirements of the county fee bill, while only four bills required reduction to the county fee bill standard. At the end of the year the accumulated

bills were prorated among the doctors rendering the service with the result that they received 16.3c for every dollar's worth of work they did. While this amount was ridiculously small, it was, nevertheless, just that much more than we would have received had we not been working on the plan, because under the old contract system no one except the contract doctor received anything for the work he did for cases under public welfare. agreement is a renewal of the previous year's plan with the exception that the appropriation has been raised forty per cent. With the increase in work it is doubtful whether the percentage received by the doctors will be greater than in 1932.

In the 1932 agreement mileage at the rate of 75 cents one way, beyond one mile from the physician's office was permitted. This appeared to work a hardship on the rural practitioner. Some investigation was done and it was found that the doctor who had traveled the largest number of miles on these cases received approximately 36 per cent of what he would have received had the cases been private cases and he had charged his usual fees. The 1933 plan includes a flat mileage allowance of 20 cents a mile one way, the total sum of which is to be deducted from the appropriation and paid to the doctors earning it before what is left of the appropriation is prorated for purely medical service. In this way it is hoped that a more equal distribution might be made so that the general practitioner in the country might receive compensation comparable to the time and energy spent by the doctors working in hospitals.

A survey of the county is in progress with the idea of determining what it cost in 1932 to do a dollar's worth of medical practice, and also what it cost to get a dollar for medical practice for the same year. When this is completed, we should have some definite argument with which to go before the Board of Supervisors when we request some guarantee that we will not be penalized for doing public welfare practice. We believe that we should at least be on the same footing as other individuals furnishing supplies of various kinds to the to the public welfare department. At present these supplies are delivered at cost to the department, and we believe that our services should be likewise compensated.

HYDROGEN-ION CONCENTRATION, ITS ELEMENTARY PRINCIPLES By GERALD MILOT, B.S., NEW YORK, N. Y.

From the Borden Research Laboratories

SINCE hydrogen-ion concentration is a common measure of acidity or alkalinity, it is imperative that all physicians understand the fundamentals of this analytical standard. What is hydrogen-ion concentration, how is it expressed and measured and why is its measurement replacing ordinary titration methods in physiological chemistry?

Review of Electrochemistry: Certain basic concepts of electrochemistry must be reviewed for a clear understanding of the hydrogen-ion theory. While it was formerly thought that acids retain their molecular integrity when dissolved in water, it is now established that a splitting or dissociation occurs. The acid molecule is apparently loosely bound. In water, part or all of it separates into two particles known as ions, bearing opposite electrical charges. These ions cannot be recovered from the solution as separate entities. Their existence, however, is easily demonstrable by electrochemical methods.

All acid solutions, therefore, contain positive ions, negative ions, and, sometimes, undissociated acid molecules. To illustrate, a solution of hydrochloric acid in water does not represent a definite number of HCl molecules permeating the liquid. On solution, the following dissociation takes place:

 $HCI = H^+ + CI^-$

Essentially, the HCl solution becomes a solution of hydrogen and chlorine ions.

All strong acids, such as HCl, HNO₄, and H₂SO₄ dissociate in entirety. The weaker acids, however, such as lactic, acetic, or butyric, are only partly dissociated in water solution. When acetic acid is dissociated, for example, according to the equation:

 $HCH_3COO = H++CH_3COO-$

part of the acid remains undissociated. The solution contains hydrogen ions, acetate ions, and whole acetic acid molecules. In general, all organic acids are incompletely dissociated while the stronger mineral acids are completely split in water solution.

It is a fundamental concept of ionic chemistry that all chemical activity, of the type that involves the union of two chemical entities to form one or more compounds, is a result of the interplay between ions and not between whole molecules. In other words, in an ionic reaction, an acid molecule may be considered to be chemically inactive until it is resolved into its component ions. Hence the chemical potency of an acid is directly related to the amount of ions present in its solutions, i.e., its degree of dissociation.

This theory explains the relative differences in "strength" between the various acids. We speak of HCl as a "strong" acid because of its intense power to react and to combine. In reality, this power is due to the complete dissociation of HCl in water and the correspondingly large amount of ions produced which are ready for chemical action.

So-called "weak" acids, such as lactic or acetic, have a milder degree of chemical activity because their solutions contain relatively fewer ions. It can now be understood why two solutions containing, respectively, equivalent amounts of hydrochloric and acetic acids, do not show the same intensity of acid characteristics. Although each requires the same amount of base for neutralization, the acid intensity of each solution is a function of the degree of dissociation of the corresponding acid and is not directly related to the amount of acid present.

Definition of Hydrogen-ion Concentration: All acids dissociate to form two oppositely charged ions. The negative ion differs for each acid and is characteristic for that acid. In solutions of hydrochloric, nitric and acetic acids, there are negative chlorine, nitrate, and acetate ions, respectively.

The positive ion produced on dissociation is the hydrogen ion and is found in all acid solutions. It is this ion which gives to acids their so-called acid characteristics, such as sharp taste and evolution of gas in the presence of metals. As was shown above, the amount of dissociation, or the number of ions present, is a measure of the activity or intensity of an acid. Hence, the determination of the actual amount of hydrogen ions in an acid solution is an effective yardstick of true acidity. To express this factor, we measure the actual weight, in grams, of hydrogen ions in a liter of solution. The result is known as the hydrogen-ion concentration.

Inadequacy of Simple Titration: If we now consider two solutions, each containing one molecular weight, respectively, of hydrochloric and acetic acid, neutralization in each case is effected by addition of one molecular weight of NaOH. Such a procedure is, essentially, a titration as commonly carried out. Using this method, the analyst would find identical amounts of acid in each solution and would report the acidities to be equivalent. Yet, as we know, these two acid solutions are by no means of the same actual strength, although containing equivalent amounts of acid. Both have the same total or potential acidity but differ in acid intensity because of the disparity in the number of hydrogen ions formed.

5 ---/- merelet It may be a question in some minds why titration with a base fails to show actual acid intensity. This is best illustrated by the classic example of the titration of acetic acid with standard NaOH. The chemical reactions involved, considered from the standpoint of ionic chemistry, explain why simple titration shows only total, potential acidity.

We have already seen the dissociation equation for acetic acid. NaOH dissociates in a similar

manner:

$$NaOH = NA++OH-$$

When the two solutions react, the following ionic interplay occurs:

Note: It is customary to indicate equilibrium in an equation by a double arrow. Furthermore, the heavy arrow shows the direction of preponderant reaction tendency. In the above, H₂O is only slightly ionized and therefore H and OH ions rush to unite. The ions of sodium acetate tend to remain separate.

If examined carefully, this equation is a key to a clear understanding of the chemistry of ions. According to the ionic theory, all chemical activity is between ions. We must visualize the molecules of the acid and the base dissociating to form ions which are then free to react. Since H₂O is only slightly ionized, there is a strong tendency for the hydrogen ion to combine, as fast as it is formed, with the hydroxyl ion which is present in excess. The rapid removal of the hydrogen ion disrupts the delicate equilibrium which has been shown to exist between the dissociated and undissociated phases of acetic acid. More acid immediately dissociates to make up this loss.

As long as there is an excess of OH ions to combine with the hydrogen ions, this cycle repeats itself until the acid is expended. If this reaction is carried out in the presence of a color indicator, such as litmus, a color change will occur at neutralization, i.e., when there is no longer an excess of hydrogen ions in the solution. At this point, we are able to calculate from the amount of NaOH used, the total acidity of the acid solution.

It will at once be seen that such a titration method cannot show actual acid intensity because the chemical reactions involve a destruction of the acid. The end result is not known until all the acid disappears, at which moment the chemist calculates the entire amount of acid that has been destroyed. Actual acidity is determined only by specific measurement of the hydrogen-ion factor.

Physiological chemistry deals with organic

acids, such as lactic, acetic, and butyric, which are for the most part only slightly dissociated. It is apparent that ordinary titration methods, applied to these acids, are subject to serious errors. For the sake of accuracy, it becomes necessary to determine the actual concentration of hydrogen ions. Before hydrogen ion concentrations can be expressed, we must revalue the concept of neutrality, the point which serves as a base for acidity measurements.

Neutrality.—Pure water dissociates to an extremely slight degree into hydrogen and hydroxyl ions.

$$H_2O = H^+ + OH^-$$

Since these ions are formed in equal quantities, there is no preponderance of either. Delicate electrometric measurements have shown that the amount of hydrogen ions in one gram of water is $\frac{1}{1000000000}$ or $\frac{1}{10000000000}$ grams. This figure also expresses the amount of OH ions in one gram of water.

Sorenson, in 1909, suggested the use of the expression pH to denote hydrogen ion concentration. Thus, in the case of water, pH = $\frac{1}{10}$. As this is an inconvenient fraction, the convention is to write pH = 7. Similarly, a concentration of $\frac{1}{10}$ ° grams is written pH = 6, and so on.

Since we can assume that water is ipso facto neutral, the value of pH = 7 is taken as the point of neutrality on the acid-base scale. Now if an acid is added to pure water, there will ensue an immediate increase in the number of hydrogen ions because of the dissociation of the acid. Should this increase amount to ten times the original quantity, the change will be from 1/10° to 1/10° grams of hydrogen ion. Following the convention, we write pH = 6. An increase in hydrogen ions of 100 times will produce a concentration of $\frac{1}{10}$ grams, or pH = 5. Hence, a solution having a pH = 5.6 has between $\frac{1}{10}$ and $\frac{1}{10}$ grams of hydrogen ions. It is important to note the inverse relationship between acidity and the concrete value of the number that expresses pH. An increase in acidity brings about a decrease in the concrete value of the pH number.

Similarly. if a base is added to pure water, the excess of OH ions introduced by the dissociation of the base, will combine with some of the hydrogen ions and thus decrease the total hydrogen ion concentration. If this decrease in hydrogen ion amounts to one-tenth, there will be only 1/10° grams in solution or pH = 8. It must be clearly understood that any solution, whether acid or alkaline, contains hydrogen ions. The concentration thereof serves as a measure of alkalinity or acidity.

To summarize, pH = 7 is the point of neutrality. Values of pH decreasing from 7 show increasing acidity. Values greater than 7 show increasing alkalinity. A unit change in the con-

crete value of the pH number corresponds to a change in hydrogen ion concentration of ten times.

Methods of Determination: The technician has two methods at his disposal for the measurement of hydrogen ion concentration. One, the electrometric method, involves expensive and elaborate apparatus plus a certain technical knowledge on the part of the analyst. Although difficult and tedious, this method permits pH determination with great exactifude, amounting to two decimal places. This corresponds to a degree of accuracy of one billionth, for values in the neighborhood of pH = 7.

Since most laboratory work does not require such fine accuracy, values of pH accurate to one decimal place are obtainable much more simply and rapidly by the second method, the colorimetric. This procedure involves the use of a group of dyes which show a graduated series of color changes at different points on the pH range. For example, a solution of bromcresol green is vellow at pH = 3.8. As the acidity decreases, the dye becomes greenish and finally blue at pH = Intermediate pH values are indicated by definite tints which have been standardized by the electrometric method. In a like sense, phenol red changes from yellow to red over the pH range of 68 to 8.4 and this indicator is selected whenever the pH of an unknown is suspected of being within these limits.

In making the determination, the standardized indicators are tried with the unknown solution by the hit-or-miss method until the pH is found to lie within a certain range. The special indicator which is affected by this range of acidity is compared with the color scale, showing accurate pH values. Excellent commercial sets of indicators and color standards are available.

BUFFER ACTION

No paper on hydrogen ion concentration is complete without a discussion of buffer action since the two are closely linked, both in theory and in practice.

When an acid or a base is added to pure water, dissociation is rapid and the hydrogen ion concentration of the solution changes sharply from pH = 7, neutrality, to its new value. Buffer substances are compounds which, when present in a solution, prevent sudden changes in pH value, as an acid or a base is added. In general, salts of a combination of a weak acid with a strong base are buffers. This phenomenon is best illustrated by a concrete example.

When sodium acetate is dissolved in water, there ensues a hydrolysis of part of the salt, according to the equation:

The heavy arrows indicate the direction in which the tendency to dissociate or recombine is preponderant. As in all ionic reactions, a delicate equilibrium exists between the various components.

Now if, to such an equilibriated system, some acid like hydrochloric is added, there is an immediate potential supply of hydrogen ions. hydrogen ion concentration would be expected to rise sharply. However, the hydrogen ions are being generated in a medium that contains a large quantity of acctate ion, due to the sodium acetate hydrolysis. We have seen that acetic acid tends to remain undissociated. Hence a large quantity of hydrogen ions and of acetate ions cannot coexist in the same solution but must unite to form the un-ionized, and therefore chemically inactive. acctic acid. The effect of the added hydrochloric acid is minimized because the hydrogen ions are combined with as fast as they are formed. spite of a large increase in total acidity, the pH value will be found to have varied only slightly. In the final analysis, what really happens is a conversion of the highly dissociated "strong" hydrochloric acid into the weak, slightly ionized acetic acid. The sudden change in hydrogen ion concentration has been averted and the solution is therefore buffered.

As the acetate ions combine with hydrogen ions, their concentration in the solution decreases. Referring to the equation, it is seen that this disturbs the equilibrium of sodium acetate and forces the reaction to the right to form more acetate As long as there remains enough salt to generate acetate ions, which are then available to bind hydrogen ions, any added hydrochloric acid will be buffered in consequence. Large increases in total acidity will cause small changes in pH until a point is reached where there are no longer sufficient acetate ions available to combine with the added hydrogen ions. Continued increments of acid will then cause sharp changes in pH since the buffer power of the salt has become exhausted and no longer presents an obstacle to the increase in hydrogen ion concentration.

Similar protective action is exerted when a strong alkali, such as NaOH, is added to a buffered solution. The function of a buffer salt, therefore, is to guard against sudden changes in pH in reactions that must proceed within narrow limits of acidity.

Application of Hydrogen Ion Methods: It can be seen at once that titration methods are of little value in controlling buffered solutions since they show only total acid and fail to give an accurate picture of the actual acidity. Any increase in total acidity is shown by titration with a base, even though buffer action precludes change in actual acidity. Since most physiological media contain impurities in the form of organic salts,

the advantages of pH determinations are apparent if errors are to be avoided.

Buffer action plays an important role in blood chemistry. The pH of the blood stream must not be subjected to sudden changes. Organic salts naturally present in the blood, act as buffers against acids that may be introduced following the ingestion of certain foods. Such acid entities are effectively held in check until safely excreted.

The action of buffers is an important factor in industrial processes, since it is doubtful if large scale chemistry involves the use of many pure reagents. Ordinary titration methods would be of little value in dealing with impure, highly buffered solutions that are to be kept within certain limits of acidity. Hydrogen ion control enters into such widely diversified industries as leather tanning, sugar refining, paper, pigment, or glue manufacturing, and boiler water purification.

The theory of hydrogen ion concentration was given widespread notice by the medical profession with the development of lactic acid milk for infant feeding. Marriott¹ determined the pH of the stomach contents in infants at definite periods after ingestion of breast milk or cow's milk dilutions. It was found that babies fed on breast milk showed a stomach pH well within the range that has been established as optimum for digestion, pH = 3.8. This acidity is reached shortly after feeding. Cow's milk, on the other hand, causes a much longer delay in reaching this figure. Because of the high buffer action of cow's milk, more time is needed for the stomach tò adjust its acidity to the proper value.

The following table shows the amount of a tenth normal solution of hydrochloric acid which must be added to 200 c.c. portions of water, of cow's milk, and of breast milk, to produce a hydrogen-ion concentration of 3.8 in each type of solution.

Amount of N	Hydrogen ion concentration			
10	Water	Cow's	Breast	
acid added		milk	milk	
no acid at start	7.0	6.6	11111K	
0.22 c.c.	<u>3.8</u>	6.6	6.9	
20.0 c.c.	2.05	6.35	6.15	
54.0 c.c.	1.68	5.95	3.8	
100.0 c.c.	1.50	5.35	2.35	
182.0 c.c.	1.35	3.8		

Over three times as much acid must be present to bring about the optimum pH = 3.8 in the case of cow's milk as in breast milk. Although most infants are able to cope with the increased buffer power of cow's milk, it is desirable, in certain conditions, to relieve the stomach from the necessity of manufacturing enough hydrochloric acid to overcome the buffer action of milk.

To achieve this purpose, cow's milk is acidified with lactic acid to the point where the acidified mixture affects the stomach acid in a way analogous to breast milk. In other words, the buffer action of lactic acid milk is akin to that of breast milk. Hydrogen ion methods were of enormous value in this work since the high buffer power of milk solution's precludes the use of titration methods.

Lactic acid milk is also made by the fermentation of fresh milk with an acid producing organism. This method gives a better, smoother product, of superior flavor, and is rapidly coming into general use now that commercial cultured milks are available in powdered form.² In the manufacture of powdered cultured lactic acid milk by the Merrell-Soule spray process, changes in acidity are accurately controlled by pH determinations.

Cultured lactic acid milk must not be confused with acidophilus milk, whose virtues lie in the fact that it is a vehicle for massive number of beneficial organisms. Lactic acid is a component of acidophilus milk but only as a by-product of the activity of the acidophilus organisms.

The theory of hydrogen ion concentration introduces a new conception of acidity and makes possible greater accuracy. Scientific papers use this standard with increasing frequency. Universal acceptance and use of pH methods in physiological work is not far distant. It remains for the practising physician to achieve a clear understanding of hydrogen ion concentration so as to be en rapport with his colleagues in the field of research.

THE HEART IN PNEUMONIA

By LOUIS H. SIGLER, M.D., BROOKLYN, N. Y.

Read before the Harbor Hospital Staff Conference, January 13, 1932.

THERE is a prevailing idea in the medical profession that death in pneumonia is invariably due to heart failure. This organ, therefore, is the center of anxiety and the target for therapy of the attending physician. We do not seem to realize that the disease is productive of complex disturbances affecting all vital centers, and if death ensues, it is a combination of factors rather than one cause which is responsible.

The factors causing the various disturbances are predominantly three-anoxemic, toxic, and septic. The first is caused by insufficient oxygenation of the blood, due to diminished lung bed, caused by consolidation, and poor absorption of oxygen resulting from swelling and exudation of the alveolar walls. How much of a relative part the toxic and anoxemic factors play in the disease is hard to tell. We do know from experience, however, that comparatively little pulmonary involvement in which case oxygenation of blood is presumably not much interfered with, may run a severe clinical course and even end in death. On the other hand, massive involvement with all potentialities for the production of severe anoxemia may be associated with mild clinical manifestations. We must, therefore, conclude that toxemia is a variable but very important factor in the disease. Where severe pneumococcemia is present, the cause of death is probably the invasion of all organs by the organism itself.

In severe cases, the respiratory and vasomotor centers seem to be affected most. At first the respiratory center is stimulated by lack of oxygen and accumulation of carbon dioxide, resulting in an increased respiratory rate. The breathing, however, is shallow, with insufficient expansion of the normal lung bed. This, together with the mucous accumulation in the smaller bronchi, results in localized areas of atelectasis with extension of the pneumonic process. A vicious cycle is thus produced. If progressive, and the organism is excessively virulent or the individual's resistance is poor, respiratory paralysis may result from excessive irritation of the respiratory center.

The vasomotor center is likewise stimulated at first. A normal blood pressure is thereby maintained even in the presence of peripheral vascular irritation and tendency towards dilation, as well as weakened myocardial tone. Sooner or later fatigue and paralysis of the vasomotor center may occur producing a fall in blood pressure, even to a fatal level.

The heart in pneumonia, like the other vital organs, may be affected by septicemia, toxemia and anoxemia. In addition, mechanical interference with the free propulsion of blood through

the pulmonary fields, and vasomotor failure may play a part in the cardiac breakdown.

Taxic and dangenic Research in the Heart

Toric and Anoxemic Effects on the Heart

Although it is reasonable to assume that considerable myocardial damage may occur from these factors, careful analysis shows very few cases of actual myocardial involvement in the course of the disease. This is shown both experimentally and clinically. Experimentally, as long ago as 1899, Romberg and Passler produced pneumococcic death in animals and found such death to be due to vasomotor paralysis without injury to the heart. In very interesting experiments on dogs performed by Newburgh and Porter1, it was found that on feeding the cardiac ventricles of dogs that died from pneumonia with healthy blood, they contracted as well as ventricles of healthy dogs. On the other hand, the ventricles of healthy dogs did not contract with full force if fed with pneumonic blood, but the ventricles from pneumonic dogs contracted with much more force if fed with similar blood. Their conclusions were that the heart in pneumonia is essentially normal and becomes adapted to the toxic blood fairly well.

On the clinical side, we have many reports tending to substantiate the same facts. T. Stuart Hart's, in a study of a number of cases of influenzal bronchopneumonia in 1918, found that patients with normal hearts did not as a rule die from cardiac insufficiency. Anatomically, also, there was no proof of myocardial damage found on post mortem examination. Paul D White3 states that endocarditis and pericarditis rarely result from pneumonia, and the myocardium in fatal cases may show cloudy swelling and necrosis. Such findings, however, are not common. Stones, in a series of 259 autopsies of pneumonia cases, found the hearts to be normal in 57.3% of lobar pneumonia, 66.1% broncho-pneumonia, and 37.9% pneumococcic sepsis. Theodore Janeway in 1907 stated that most cases of death in acute infectious diseases are attributable to vasomotor · failure and not to heart affection.

Little electrocardiographic study has been done in pneumonia. From available data, however, we may conclude that very few inherent changes occur in the electrocardiogram in this disease. Burnett and Piltz* reported some changes in conduction and in the T wave in a few cases. We occasionally get simple tachycardia, paroxysmal tachycardia—auricular, nodal, and ventricular—as well as auricular flutter and fibrillation. These are, however, not distinctive of the disease, and are uncommon.

Thus, experimental, clinical, and electrocardiographic evidence point toward the escape of the

محمودة

heart from serious damage in most cases of pneumonia. Furthermore, even in the presence of anatomic myocardial damage, the heart may perform its functions well.

Mechanical Interference with Heart Action

Like the toxic and anoxemic effects on the heart, the mechanical interference with the free flow of blood through the lungs caused by consolidation, should theoretically produce heart fail-To overcome a rather acutely increased pressure in the pulmonary artery, the right ventricle is expected to be overburdened. In actual practice, however, we find good adaptation of this chamber by moderate dilation and compensatory increase in force of ventricular con-Unless acute right ventricular failure occurs, clinical manifestations indicative of such failure are not found in the course of pneumonia. In Stone's series, only 39.4% of fatal cases of lobar pneumonia, 33.6% of fatal bronchopneumonia, and 20.8% of pneumococci sepsis showed dilation of the right ventricle on post mortem examination. Assuming that the average percentage of cardiac dilation in fatal cases of pneumonia is 31, and that the average mortality rate in pneumonia is 20%, we may assume that only in about 6% of cases of pneumonia may acute cardiac dilatation be the cause of death.

VASOMOTOR FAILURE AFFECTING THE HEART

The most serious condition that may affect the heart and the other vital centers of the body is vasomotor failure with its peripheral vascular The blood pressure slowly, or more paralysis. often suddenly, falls. The vital centers as the brain, the kidneys, as well as the heart, suffer from local anemia, which may contribute to the causes of death. But are we to attribute death in these cases to heart affection or to sudden vascular catastrophy? It is true that the heart may show clinical abnormalities under such conditions. We may find marked weakening, or almost disappearance, of the first sound; murmurs may be present; occasionally there may be some form of tachycardia and arrythmia. But all these may be considered to be merely manifestations of anemia of the heart muscle.

PRIMARY MYOCARDIAL AFFECTION

It is important, however, to recognize primary cardiac affection and failure when it does occur. The clinical manifestations of these hearts are similar to those of the abnormal heart in other conditions. These may be divided into two groups—first, the group presenting the various tachycardias and arrythmias, without definite evidence of failure, and second, the group presenting definite failure, with or without tachycardia and arrythmia.

The group presenting the tachycardias and arrythmias.—Here are included hearts showing excessively high rates disproportionate to the temperature, and abnormal rhythms. Many of these cases, if allowed to go on without digitalis therapy, will sooner or later fail, due to over-activity of the ventricular musculature, in addition to the other factors aforementioned. Many of these cases can be recognized by ordinary clinical methods, although some require electrocardiographic study for differential diagnosis. It must be remembered, however, that the mere occurrence of an arrythmia does not spell death. Occasionally we see such cases, especially those presenting auricular flutter, return to a normal mechanism and failure averted by sufficient digitalization. Cases of fibrillation, where a normal sinus mechanism is ordinarily not restored by digitalis, will obtain the benefit of the drug by its blocking effect and slowing of the ventricular rate.

The group presenting heart failure.—It is important to remember that failure may occur even in the absence of the tachycardias and the ar-The first evidences of failure are a rythmias. diminished pulmonic second sound, and definite cardiac enlargement. There may also be some diminution in the urinary output, increased dyspnoea and the development of rales at the bases of the lungs outside of the consolidated area. If not attended to at once, congestive failure may soon become evident. The liver may become engorged, pulmonary congestion increases and peripheral venous stasis and edema may develop.

TREATMENT

The treatment of the heart in pneumonia, then, should be in the vast majority of cases not the treatment of the heart but the treatment of the underlying diseased processes. Digitalis should be used only when indicated. By confining our treatment to the heart alone, we merely sprinkle water on a conflagration which is constantly fed with fuel. Besides, to quote T. S. Hart², "the employment of a method directed against the wrong conception of the pathology may lead to a false sense of security and keep us from directing our efforts to secure remedies better fitted to combat the true pathologic condition."

The general indications for treatment are: first, to combat the toxemia; second, to overcome the anoxemia; third, to maintain the vasomotor tone; and fourth, to support the heart only when such support is called for.

To combat the toxemia, attempts have been made to establish early immunity by serum. The results, however, apparently do not justify the risk of anaphylaxis. The majority of reports of serum treatment are certainly not favorable against types II, III, and IV pneumococci. Only in type I does it seem to decrease the mortality

Cecil and Plummers, in a study of 1,161 cases of type I pneumonia, found that of 412 cases not receiving scrum, 28.2% died. Of 239 treated with Felton's concentrated scrum, only 20% died, and only 11.7% died if treated within 72 hours of onset. Thus, even these figures are not encouraging, and we must still resort to other and older methods of treatment to combat the disease.

The best means of overcoming the toxemia is by copious ingestions of fluids and alkalies, as citrates, and properly regulated bowel elimination by unexhausting drugs. To help overcome the anoxemia, early inhalation of oxygen and carbon dioxide is necessary. Henderson, Haggard, Coryllos, and Birnbaum' feel that if early inhalation of carbon dioxide be given in pneumonia, extension of the process would be prevented and the disease checked. They induced pneumonia in dogs, experimentally, by virulent pneumococci. The disease was then checked and the animals were restored to health by inhalation of sufficient carbon dioxide to cause deep breathing, and continuing such inhalation until the process was cleared. They used 5 to 7% of carbon dioxide mixed with ordinary air. In using a concentration of oxygen of over 40% for a prolonged period, there is, however, a possibility of harmful effects. Faulkner and Moore studied the effects of varying oxygen concentration on normal animals. They found that in atmospheres of over 70% of that gas, symptoms of anoxemia developed. The symptoms were drowsiness, anorexia, loss of weight, dyspnoea, cyanosis, and death. The explanation for this anoxemia was found on post mortem examination in a diffuse hemorrhagic edema of the alveolar walls of the lungs, interfering with the diffusion of oxygen even in the presence of a high atmosphere of that gas.

To prevent and to treat vasomotor failure, cool alcohol sponging and intravenous saline and glu cose injections introduced gradually are to be resorted to. Kastlin and Lynch⁸ recommend 400 to 600 grams of dextrose to be given daily in the proportion of 200 grams to 1,000 c.c. of water

with lemon juice by mouth. If the patient is unable to take up that much by mouth due to nausea, and if toxemia is marked, they used 200 c.c. of 25% solution of dextrose intravenously 4 to 6 times a day, each injection to take at least a half hour. If the blood pressure is very low, intravenous injections of 5 to 15 minims of adrenalin chloride 1 to 1,000 may be given in addition.

As to the use of digitalis, the consensus of opinion is that if improperly used, it is harmful. Wyckoff, Du Bois, and Woodruff⁹ found a decided increase in mortality of 835 patients receiving the drug. They believe that routine administration of the drug is dangerous. Burrage and White²⁰, in a study of 221 eases, found that patients receiving digitalis in occasional doses had a mortality of three and one-half times that of those not receiving any at all. Cases, however, that were kept digitalized, had a mortality of approximately only one-half of those not receiving the drug. Somewhat better results are those of Colm and Jemison, and others.

That digitalis has its pharmaeologic effects on the heart in pneumonia as in any other condition is well established. It must be used, however, only when indicated and then in sufficient doses to have its full effect. The main indications for its use are auricular fibrillation and flutter, and heart failure. The response in many of these cases is excellent. I have used it in a case of auricular paroxysmal tachycardia, where it supposedly has no effect, with excellent results.

Where the drug is indicated, the rapid method of digitalization must be employed by giving large doses at frequent intervals until its full effects are produced or until toxic symptoms shown. The effects to be looked for are slowing of the heart in auricular fibrillation; conversion of flutter into a normal mechanism, and reducing congestive failure.

No mention is necessary of routine symptomatic therapy, for each condition must be met as it arises.

THE DIFFERENTIAL DIAGNOSIS IN RECURRING ATTACKS OF JAUNDICE FROM COMMON DUCT STONE AND PANCREATITIS; WITH REFERENCE TO BILE SAND.

By R. FRANKLIN CARTER, M.D., NEW YORK, N. Y.

From the New York Post Graduate Medical School of Columbia University.

In the common duct or from subacute pancreatitis the diagnosis of obstructive jaundice can usually be made without difficulty. However, when the gall bladder has been previously removed and the attacks of jaundice occur, as in two patients herein reported, the differential diagnosis between common duct stone and subacute pancreatitis has a very important bearing on the type of treatment to be selected. The presence of bile sand in the aspirated duodenal content may be relied upon to differentiate the two conditions and to determine the type of treatment to be utilized.

The clinical history is similar in both conditions in many respects, and particularly is this true during the early stages of the attacks and at the time when a correct diagnosis is of such importance in preventing serious damage to the liver and pancreas. As a rule the onset of the attack is acute in both conditions; the pain is severe, continuous and located in the mid - epigastrium with radiation through to the back; vomiting usually occurs without affording relief; distention of the abdomen varies and is apt to be more pronounced in patients with pancreatitis; tenderness is constant in the upper abdomen, but not definitely localized in either; and, rigidity is voluntary. The temperature rise is usually sudden and variations occur in different attacks in both instances, a rise to 104 or 105 is not uncommon in late attacks. Chills are frequent and they often initiate the attack.

The attack varies in intensity, character of the pain, rise in temperature, appearance of the jaundice and length of time in the same individuals at different times. The residual symptom of a heavy dull sensation amounting to a dull pain in some instances located in the mid-epigastrium is of importance for as the attack subsides in a patient with a subsiding subacute pancreatitis he will surely speak of this deep seated sensation, whereas a patient that has been freed from an impacted stone seizure feels immediately and completely relieved of all pain when both conditions do not exist in the same individual.

The cholecystogram with the dye is of no value for if obstruction of the common duct is shown, as it rarely will be, the cause cannot be determined unless the stone itself visualizes. As common duct stones rarely contain opaque material, they will seldom be seen.

Liver function tests do no more than show the presence or absence of an obstruction. These may be important in determining the necessity of drainage of the common duct when evidence of liver damage begins to appear, but they do not aid in the differentiation of the two conditions.

During the subsidence of the attack an aspiration of the duodenal content as practiced by Lyons with the Lyons or Twiss tube and examination, both macroscopically and microscopically, for particles that macroscopically look like ordinary sand and microscopically are crystals of calcium bilirubinate, cholesterol and calcium is indicative of stone in the common duct. The absence of such substances is proof of constriction of the common duct having been due to pancreatitis in the great majority of cases. This procedure commends itself because it is simple, easy to apply and in-expensive. Two case histories are reported to demonstrate its value and these findings have been noted to be correct at operation in four other cases

Case No. 68232. A white female, aged 57 years; duration of case record 8-26-31 to 6-1-32; result: Apparently cured. The history was typical of gall bladder disease of two years' standing with nine intermittent acute attacks without the occurrence of jaundice until the last attack. A gastro-intestinal Roentgen study was negative, the icterus index 9.3, Van den Bergh, direct negative, indirect positive. No gall bladder cholecystogram with the dye was made.

Examination on the sixth day after admission revealed rigidity, tenderness of the right upper abdomen, temperature 101, pulse rate of 90. A diagnosis of acute cholecystitis was made and operation advised.

Operation: A cholecystectomy was done with drainage of the common duct through the open cystic duct by means of a tube sewn into the opening.

Findings: Acute cholecystitis, hydrops and stone impacted in cystic duct. The pancreas was firm, not enlarged and no stone could be demonstrated in the common duct.

Post-operative Course: Normal reaction and progress for nine days with drainage of a clear, amber bile from the common duct. On the ninth day the drainage tube was

clamped off, a chill with high fever resulted. The clamp was removed and the tube came away two days later with no further drainage of bile. Three days later another chill with fever and acute abdominal pain occurred. During the next month there were three attacks of fever, chills and a few days of jaundice and light stools followed each attack of pain. The patient left the hospital twenty-six days after operation.

The patient was readmitted to the hospital in the sixth post-operative week, acutely ill with jaundice, fever and acute abdominal The icterus index was 71.4, Van den Bergh, direct and indirect, 4 plus; cholecystogram after the administration of dye re-

vealed no shadow.

Diagnosis: Cholangitis with obstruction by a stone in the common bile duct.

Operation: The common bile duct was found to be three times its normal size, filled with clear, amber colored bile and to contain no stones. The pancreas was acutely inflamed but not hemorrhagic and there was no fat necrosis within the abdomen. A drainage tube was sewn into the common duct opening.

Post-operative Course: The drainage from the tube continued for fourteen days when it ceased because the patient inadvertently pulled the tube out of the wound. Six days later the attacks of acute pain, jaundice, fever and The attacks of jaundice chills reoccurred. continued at irregular intervals for five months and during this time duodenal drainage specimens of bile showed a clear, amber fluid free from crystals of cholesterol and calcium bilirubinate.

Two months after the second operation an abscess formed in the operative scar, below the drainage site, which ruptured spontaneously with the discharge of a large amount of slough and scropurulent material. The attacks of jaundice continued to occur for three months until the final attack which was very severe and lasted for several weeks. Following this attack the patient began to get well and she has regained her strength and there have been no attacks of jaundice for one

The second operation with drainage had no apparent effect upon the pancreatitis and had a duonenal drainage been done with negative findings before operation the absence of a stone should have been determined.

Case No. 11. Hospital No. 63051. A male, white, aged 65 years.

The patient was admitted 3-2-31, with a history of recurring attacks of cholecystitis for four years with four attacks, the last of three weeks' duration with fever and a loss of weight of twenty pounds. There had been no jaundice with any of the attacks. The icterus index on admission was 7, Van den Bergh, negative.

A diagnosis of cholecystitis and cholelithiasis was made and a laparotomy revealed an acute purulent cholecystitis with choleli-The common duct was not dilated thiasis. and it was not explored for stone. The patient made a good recovery and remained well

for three months.

Then, the attacks of jaundice, fever, chills and abdominal pain began and they were treated at another hospital until the patient returned to this clinic. Examination at this time revealed an icterus index of 18 with a positive direct and indirect Van den Bergh reaction.

The attacks of pain became more frequent with increasing jaundice and the patient was admitted to the hospital fourteen months after the first operation with an icterus index of 100. One week later the jaundice was clearing with an icterus index of 25. A duodenal drainage at this time revealed a normal bile stained fluid in which the particles of sand could be seen macroscopically. Under the microscope the particles could be identified as masses of cholesterol, calcium and calcium bilirubinate crystals.

A diagnosis of stone in the common duct was made and at operation a large soft stone was found in the lower end of a dilated common bile duct. The pancreas was not enlarged nor did it appear involved. A tube was sewn in the opening in the bile duct. Bile drainage ceased when the tube was removed on the tenth day and the patient has remained free of symptoms for one year.

Conclusions

Recurring attacks of jaundice with pain. fever and chills following cholecystectomy for cholelithiasis are usually due to either pancreatitis or common duct stone.

The differential diagnosis between creatitis and stone in the bile duct can usually be made by examination of the duodenal contents for bile sand, viz., cholesterol and calcium bilirubinate crystals in the aspirated duodenal specimens.

GAS BACILLUS INFECTION COMPLICATING APPENDICITIS

By CLARENCE A. TRAVER, M.D., ALBANY, N. Y.

Read before the Albany County Medical Society on Feb. 23, 1932.

ASE REPORT: C. S., age 24 years, Albany Hospital No. 3333-30-A young man, twenty-four years of age, was admitted to the hospital on May 10, 1930, ten days after the onset of abdominal pain. When the pain first came on, it was diffuse in character and associated with fever but no vomiting. Later the pain became localized in the right hide of the abdomen and was associated with anorexia and vomiting. He continued to do some farm work and even drove a tractor, but he had considerable cramplike pain. He consulted a druggist who gave him castor oil. Then he consulted Dr. Joslin of Voorheesville, and my father was called in consulta-There was scarlet fever in the family. The past history was negative, and the physical examination was negative except for the abdominal There was marked tenderness and findings. muscular rigidity over the right side of the abdomen, and a mass was felt at McBurney's point. The temperature was 101°, the pulse 88, and the respirations 20. White blood count was 12,500. The urine showed a faint trace of albumen and a few leucocytes. A diagnosis of appendiceal abscess was made from the history and physical findings.

Under ether anesthesia a muscle-splitting incision was made through the right rectus muscle, and free drainage was instituted without soiling the general peritoneal cavity. The appendix was not discernible in the abscess cavity, and it seemed wise not to prolong the operation or increase the risk to the patient by searching for it. A culture was taken, and the wound closed in layers about a large drainage tube. The patient was returned to his room in good condition, and a saline infusion was started.

The morning following the operation the patient was in good condition. The morning temperature was 98°, and the evening temperature 101°. The pulse remained between 90 and 100. patient had a fair day, but in the evening he vomited about ten ounces. The dressing was changed twice; nothing remarkable was noted. There was no swelling about the wound and no discoloration of the skin; no unusual odor was noted. During the night he complained of severe "gas pains" which were not relieved by the insertion of a rectal tube and were influenced very little by three hypodermic injections of morphia, gr. 1/6. He vomited small amounts of water, but retained about thirty ounces. The next morning he complained of severe pain in the epigastrium. The nurse noted that there was considerable foul smelling drainage from the wound. The temperature was only 100°, but the pulse was 130. The respirations were thirty-six. There

were redness and swelling in the epigastrium, The swelling extended into the right axilla. Two incisions were made into this swelling; one near the xyphoid process and another in the axilla. Gas escaped from these incisions and also from the right rectus operative incision which was draining profusely. Cultures were taken from the three incisions. At this time a clinical diagnosis of "gas bacillus infection" was made. Radical treatment such as excision of muscle bundles or free incisions did not seem possible because of the widespread infection and because of the moribund condition of the patient. Taundice developed, and the temperature rose to 106.8° by rectum. Death followed seven hours after gas was found in the tissues and forty-three hours after operation. Antiserum for treatment of gas gangrene was not at hand, and although I have used it with good result in a case of gas gangrene that followed a compound fracture of the forearm, I doubt whether it would have changed the outcome in this instance.

Autopsy was done two hours after death and revealed, among other things, an interesting condition of the right rectus muscle. third of the muscle was pinkish in color, soft, and necrotic; and from it there could be expressed a hemorrhagic, purulent fluid containing gas bubbles. There was gas in the subcutaneous tissues of the abdominal wall and of the chest wall. The appendix was gangrenous and lying in an abscess cavity whose walls were black and necrotic. There was an area of localized peritonitis extending upward behind the cecum to the under surface of the diaphragm, and there was a fibrinous exudate on the convex surface of the liver. There were gas bubbles in the large abdominal veins, in the inferior vena cava, and in the heart. The heart muscle appeared normal. There were no abscesses or gas bubbles found in the liver, either on gross or microscopical examination. However, microscopical examination showed evidence of gas in the gastric mucosa, in the pancreas, and in the kidneys. The rectus muscle showed much hyaline degeneration with much polymorphonuclear infiltration. There were large areas of necrosis containing clumps of bacteria; also much interstitial œdema with many small gas Vessels showed mural thrombi. tures showed Bacillus welchii as well as staphylococci, streptococci, colon bacilli, and rare pneumococci. The original abscess contained Bacillus welchii as shown by the culture taken at the time of operation. Subsequently the same organism was found in the abdominal wound, in the incision near the xyphoid process, and in a blood culture taken two hours post mortem. It was not found in the axillary incision, although there was gas in the tissues at this point. I believe the infection came from the intestinal canal and that the infection spread due to contamination of the abdominal wound (split rectus muscle), although it is possible to have the infection in "clean" cases when the catgut is improperly sterilized.

Winter2 was the first to describe employsema of the abdominal wall as a complication of laparotomics. He reported two cases. This was in 1889, and it was then believed that air left in the abdominal cavity was the cause of the emphysema which spread through the subcutaneous tissues. Heil3 then collected twenty cases from the literature and gave the results of his experimental work on animals and human bodies to prove that the emphysematous condition might be due to air left in the abdominal cavity at the time of operation. Veillon and Zuber were the first to note the presence of Bacillus welchii, which they ealled Bacillus perfringens, in infections of the appendix. Russell' reported two cases of the infection from the gynccological service at Johns Hopkins Hospital in 1897. One of these followed suspension of the uterus; the other a panhysterectomy in which the intestine was inadvertently opened. Dayton⁸ reported a case with emphysema involving the neck, and supra- and infra-clavicular regions following a perforated gastrie ulcer. Other instances have followed abortions, hypodermic injections, operations on the gall bladder, on the genito-urinary tract, and on the gastro-intestinal tract. The incidence in wounds during the World War varied from three to ten per eent, and the infection is not infrequent in civil life as a complication of compound fractures. In a recent article in Surgery, Gynecology and Obstetrics Millare tabulates 607 cases of gas gangrene occurring in civil life.

In 1915 Simonds of the Rockefeller Institute stated that the relation of anaërobes in general, and of Bacillus welchii in particular, to appendicitis was still unsettled. He found Bacillus welchii in the sporulating form in pus from an appendiceal abscess and found spores in ninety per cent of normal appendices obtained at autopsy. The organism was present in approximately one hundred per cent if the appendix contained fecal material. Like the colon bacilli, anaerobes are normally present in the intestinal tract and may invade the appendix secondarily. Once a foothold is obtained, the anaërobes are capable of producing potent toxins, supportation, and gangrene. They also have a symbiotic influence upon the aerobes present but are unable to attack living, healthy tissues. The difficulty in the individual case arises in deciding whether or not the anaërobes are growing and toxic.

Jennings⁸ states, "It is evident that Bacillus welchii is present in the lumen of most appendices and is frequently found outside the lumen

of the gut in an actively growing form in appendiceal abscess, in localized peritonitis, and in a rather large number of cases in the free peritoneal exudate. In most cases its activity is eut short by operation with removal of the appendix and adequate drainage.

Gas bacillus infection of the abdominal wall is a rare condition. Butler® reports two examples and states that these were the only instances to develop in a series of approximately 7,000 laparotomies over a period of fifteen years. In one of these two cases the infection followed an appendectomy; in the other, a eolostomy. Acute gangrenous appendicitis is perhaps the most frequent abdominal condition following which the Bacillus welchii manifests itself in the form of gas gangrene. According to Millar's recent article® forty-eight eases have been reported following operations; eight of these followed appendectomy.

Jennings⁸ at the Brooklyn Hospital has adopted the following routine: In all cases in which a gangrenous change is apparent in the appendix 100 e.e. of serum (polyvalent antigangrenous serum) are added to 1,000 c.e. of normal saline and given by hypodermoclysis. Anaērobie and aērobie cultures are made from the peritoneal extidate in the immediate vicinity of the appendix and from any fluid found in the pelvis. Further administration of serum is guided by the result of the cultures and by the course of the case. If indicated, 200 e.e. may be given daily for two or three days.

For use in general surgery the polyvalent serum is now obtainable mixed with tetanus antitoxin for prophylactic injections. It is as easily administered as tetanus antitoxin alone, and it should be used more generally. The cost is about three dollars for the prophylactic dose.

EDUCATING FISCAL BOARDS

The service of medicine has outrun that of social and economic relief in the care of the sick. Doctors are doing their share of giving relief to the needy poor; and if the service is insufficient, the fault lies in the hospitals, the public health nursing, and the Welfare officers. Delay in donating the means for relief has always characterized government officials and the people themselves to a far greater extent than physicians.

The people do not realize that the peculiar services of the doctor account for only onethird of the cost of sickness; and that hospitals, nursing, economic relief, and other services cost twice as much as the doctor. Many boards of supervisors are reducing their appropriations for public health nursing thereby crippling the service of medicine. The treatment of this hypofunction of the board is education to be supplied by county medical societies.

THE PUBLIC RELATIONS OF PHYSICIANS

The report of the monthly meeting of the Committee on Public Relations which is printed on page 957 of this Journal, and that of the Committee on Temporary Emergency Relief on page 958, illustrate the numerous contacts which physicians have with other groups of persons that are interested in the solution of public health problems.

The growth of a sense of responsibility for social conditions is a striking characteristic of the present decade. The scientific physician has always felt a personal responsibility to relieve the suffering of individuals with whom he comes in intimate contact. But it is only in the last decade or two that the medical profession has developed a keen sense of collective responsibility to give impersonal relief to groups of sufferers whom they will never see. This new consciousness of social duty has affected all classes of people, so that philanthropic organizations have sprung up, each designed to deal with a specific condition in sociology or economics.

It happens that sickness, poor health, and physical defects enter into most conditions with which philanthropic organizations deal; and so physicians have been asked to contribute not only their proportionate share of relief money as citizens, but in addition to donate the entire service of diagnosing and treating the medical conditions. However, the relief agencies, especially those of an official nature, are now beginning to recognize the justice of paying the physicians for their professional services on a fee basis, rather than by contract, or giving them no pay at all. As a matter of fact the fees in most instances cover merely the direct expense to which a physician is put in treating a case, but this is better than nothing.

One excellent accomplishment of the voluntary philanthropic organizations is that of arousing the people generally to their social duties in helping one another. A quarter of a century ago, when a doctor was called to pneumonia case, for example, the burden of getting a nurse, filling a prescription, and securing food for the family fell on the doctor, especially if he was a rural practitioner. He often solved the problem by referring the case to some good woman friend, or to a church society. But today, the doctor calls up the public health nurse who gets into immediate contact with a half dozen relief organizations.

The Committee on Public Relations is largely a liaison committee between the medical

profession and the several Departments of the State Government that touch upon health; and its great function is to develop agreements as to the relative share of the burden of medical relief which shall be borne by the physicians and by the people generally. Five important subjects that were discussed at the last meeting were venereal disease clinics, blood donors, crippled children, physical defects of school children, and the hard of hearing. In each of these subjects the committee dealt with a definite organization or a division of Government, which was vitally interested in the same problem

The State Medical Society Committee on Temporary Emergency Relief was formed in order to assist the officials of New York State to give relief to the unemployed, both economically and medically. The State supplies the money and distributes it through the Welfare Commissioners of the several counties. It supplements the Welfare Law, in that it provides State funds in addition to those supplied by local governments.

On reading the comments of the Committee one gets the impression that the State Government and the medical profession are working in close cooperation to provide medical service to those unable to pay for it. However, the report recognizes that physicians do not score one hundred per cent in doing their part; their failures are largely clorical—conditions which are especially aggravating to administrators who are compelled to give an account of every penny of funds and to justify the detail of every method of action.

The evidence of the present interest of physicians in their relations to other civic organizations is in striking contrast with conditions a decade or two ago. The New York State Journal of Medicine for July, 1908,twenty-five years ago,-does not record a reference to public relations, except a brief editorial condemning correspondence schools for nurses. The Journal for July, 1923,-ten years ago,-is almost equally barren of articles on the civic relations of physicians, but it discusses editorially the duty of a physician to attend cases remote from a doctor. But today every journal contains several pages of news of the civic activities of physicians and their medical societies.

The New York State Journal of Medicine and the Journals of the Medical Societies of the other States, afford abundant evidence of the willingness and eagerness of practicing physicians to discharge their civic duties.

MEDICAL PROGRESS

The Ketogenic Diet in Normal Individuals: a Biochemical Investigation.—Frank L. Apperly and Joan H. Norris state that, although a number of reports have appeared on the good results of the treatment of epilepsy and asthma by the ketogenic diet, no one seems to have made a complete examination of the changes in the acid-base balance of the blood under the influence of this diet. They, therefore, undertook such an examination in three healthy women students, aged from 21 to 23. The tabulated results show that in all subjects there was a slight fall of plasma carbon dioxide, a more marked fall of red cell carbon dioxide, and a fall in the ratios of cell carbon dioxide to plasma carbon dioxide, and of cell chloride to plasma chloride. These findings were interpreted according to the laws relating to the distribution of chloride, bicarbonate, and hydrogen ions in the blood, as worked out by Van Slyke and his associates. The result showed that alkalemia was almost constantly present. It is suggested that the alkalemia is the result of hyperpnea produced by direct stimulation of the respiratory center by certain ketone derivatives in the blood, and that in these experiments this effect outweighed any acidemia produced by ketogenic acids, and further, that the failure of the ketogenic treatment of many cases of epilepsy and asthma is due to the relative preponderance of the former effect. A study of any conditions tending to raise the ketonic acid: acetone ratio would be of benefit in the treatment of epilepsy and asthma.-American Journal of the Medical Sciences, June, 1933, clxxxv, 6.

Superalimentation.—Lea A. Riely says that although we can estimate the nutritional needs of an individual by his size, body surface, age, sex, and the type of work he expects to do with as much accuracy as the amount of a certain specification of steam coal to carry a ship from one point to another, nutrition will never be governed by mathematical accuracy. There is in normal man some regulatory mechanism which balances appetite and desire for physical exertion. Unconsciously a man who eats too much feels the need for a little more exercise, and he takes it; or if his activities are restricted his desire for food is lessened. When this safety-valve action is obtunded unrestrained appetite has its sway, and we\get the chronic type of overeating; this leads on to obesity, which is altogether a matter of overeating. In adults who have access to a liberal food supply the memory of appetite is probably a greater factor in the ingestion and di-

gestion of food than hunger. Under these circurnstances appetite and habit supplant hunger as nature's dietary guide. Superalimentation, like overdrinking, is a disease. We have been slow to realize the effect of overeating on the heart and arteries, the lungs, kidneys, and gastrointestinal tract with its accessory digestive glands. Many think that temperate eating has been a potent factor in our diminished death rate The surgeon looks during the depression. askance at the obese patient. The internist sees him as an extra hazard because when he is febrile or fasting he breaks up his fat into fatty acids with resulting acidosis. The insurance actuary finds that he cannot write these patients at an equal rate with the normal or underweight person, so the obese individual is a marked man wherever he turns. It is universally conceded that overfeeding is one of the causes of gout. It has been shown that there is a preponderance of cases of diabetes among the obese. Once pathological physiology begins, the metabolites of carbohydrate, fat, and protein produce deleterious effects on the arterial tree, with resulting damage to various tissues. According to Dublin's statistics for the Metropolitan Life Insurance Company, expressed as percentages of the death rate of normals as a group, diabetics have a death rate two and one-half times in excess of normal, but extreme overweights have a mortality eight times the normal, and thirteen times the underweights. The figures show a similar excessive mortality from organic heart disease and arterial disease among overweights. The incidence of angina pectoris among older overweights is twice that for normals. Verily, the glutton digs his grave with his teeth .- Southern Medical Journal, June, 1933, xxvi, 6.

Modern Views on the Mechanism of Gall-Stone Formation.-In reviewing our knowledge on gall-stone formation, David H. Patey starts with Naunyn's classical theory, which dates from the last century, according to which the essential factor in the formation of gall-stones was infection, usually of intestinal origin. Later the importance of metabolic factors began to be realized, particularly by Chauffard in France. Aschoff attempted to reconcile the two views by describing two types of gall-stones, one the result of pure metabolic factors, the other the result of infection. Rosenow's claim that there are certain types of streptococci with a selective affinity for the gall-bladder has not won general acceptance, but anaerobic organisms have been shown to be not infrequent invaders. The general opinion now

is that there is some relation between infection and gall-stones, since the gall-bladder wall is infected in 70 per cent of cases, the fluid contents in 40 per cent. It is on the biochemical aspect that the greatest advances have been made, and this possibly affords the most promising line of investigation at the moment. The metabolism of cholesterol, the question whether the gall-bladder absorbs or secretes cholesterol, the factors responsible for the varying amounts of bile acids and cholesterol secreted in the bile by the liver, and the effect of inflammatory and other lesions of the liver and biliary passages are all of great importance in this connection. Schade's work on the physico-chemical aspects of gall-stone formation is interesting. He states that failure to explain biliary and urinary calculi on simple laws of solution is because of the colloids in body fluids which increase the stability of the solution. He says the pure cholesterol calculus is due to precipitation of cholesterol from a hypersaturated solution, but it is a special type of precipitation, resulting from the presence of small amounts of fatty substances in the bile. The common cholesterol-pigment gall-stone, on the other hand, he believes is inflammatory in origin, due to the presence of an appreciable amount of irreversible colloid in the gall-bladder, which acts as a binding material for the crystalloid elements. The chief surgical contribution to the pathology of gallstone formation in the last twenty years or so has been the discovery of the "strawberry gall-bladder." This condition at present affords an inportant field of study for the etiology of gallstones. The evidence that vitamin deficiency is a factor in gall-stone formation is very slender. On the statistical side the most important contribution is that of Gross, especially her conclusion that married women are no more liable than single to gall-stones. The three chief factors postulated by Naunyn as predisposing to stasis of bile-namely, lack of exercise, tight lacing, and pregnancy-are all open to serious criticism in the light of modern knowledge. It is of interest that gall-stones seem to be more common in the more variedly and richly fed peoples of Western civilization than in the East .- British Medical Journal. May 20, 1933, i, 3776.

Successful Treatment of Purulent Septic Meningitis Due to Streptococcus Haemolyticus, of Orbital Origin.—G. Canuyt, B. Tassowitz, and Ch. Wild report the case of a girl of 11, in whom, following a wound inflicted upon the lower left eyelid by a twig, suppuration developed, with violent headache and fever, presenting on the tenth day a clear meningeal syndrome. The purulent character of the cerebrospinal fluid, with 17,000 white cells per cubic millimeter, a polymicleosis of 90 per cent, the presence of numerous altered and clumped polyniclears as well as of microbes, and the absence

of macrophages, all combined to render the child's condition very grave, and the prognosis extremely unfavorable. Surgical exploration of the internal wall of the orbit revealed no lesion at the level of the ethmoid region. A general anti-infectious treatment was carried out consisting of intravenous injections of a septicemic antitoxin and the production of a fixation abscess. Cultures of the cerebrospinal fluid revealed colonies of Streptococcus hamolyticus. This led to treatment with Vincent's antistreptococcus serum in large doses of 80 c.c. per day, of which 40 c.c. was given intravenously and 40 c.c. intramuscularly. The following evening the cerebrospinal fluid was distinctly less cloudy, the white cells less frequent, and the polynucleosis had dropped to 68 per cent; no microbes could be observed, and 2 per cent of macrophages had appeared. Cultures remained sterile. In the days following there was considerable clinical improvement, but the persistence of 51 per cent of polynuclears still made the prognosis reserved. Two blood transfusions were now done, on the tenth and twelfth days respectively of the treatment. The patient received in all 1,010 c.c. serum, one-half of which was given intravenously and the other half intramuscularly. During convalescence an acute left otitis media with a mastoid reaction developed, for which, despite early paracentesis, trepanation proved necessary. The results were excellent, the patient making a complete recovery. The case shows once more the happy effects of Vincent's antistreptococcus serum, associated with transfusions and fixation abscess in streptococcus infections, which made it possible to save this girl attacked by a purulent septic streptococcus meningitis. It also shows that it is not necessary that the serum be injected into the spinal canal, and that results are excellent when it is injected into the general circulation, especially intravenously. The case also demonstrates that daily lumbar punctures for the purpose of examining the state of the cerebrospinal fluid constitute a valuable element in prognosis, since they indicate much more clearly than do the symptoms whether the meningitis is evolving toward a fatal result or toward a cure.-Bulletin de l'Académie de Médecine, April 11, 1933.

Treatment of Adiposity.—Superfluous fat, according to F. Segesser, must go by the same way it came. Adiposity of an exogenous nature, as distinguished from obesity of endocrine origin, arises through an intake of nutriment in excess of the output of muscular energy; more food is ingested than the body uses up. Such adiposity disappears when the individual, by increased muscular exercise and diminished intake of food, uses up more nutriment than he takes in. To take a reducing treatment and then return to the same old habits of overeating and overdrinking is of little value; the

patient must return again and again for renewed treatment. He must be made to understand exactly how to adjust his diet and his muscular activity to a new regimen. diet of those undergoing treatment for obesity must for the most part be an undernutritive one. Once or twice a day the heart condition is examined and the weight taken: then according to the findings the patient is put on a diet of tea, grape juice, milk, potatoes, bread, fruit, raw food, vegetables, or on a normal diet. An occasional change is desirable. The Karell milk cure is quite useful, but patients tire of milk exclusively; a diet of raw food gives just as good results, is full of variety, and more rational because of its richness in vitamins and poverty in salt. Bread days serve to remove surplus water from the organism; grape juice days are welcomed by those obese individuals who suffer from thirst. During periods of undernutrition or fasting, the patients are not put to bed unless the cardiac condition demands it. Every morning before breakfast there is a gymnastic hour, in which all patients whose hearts permit participate. many corpulent persons, especially women, the musculature is atrophic and needs to become toned up; particularly do abdominal muscles require regeneration through walking, deep breathing, and other forms of exercise. addition certain forms of physical treatment are given, such as light and sun baths, vapor baths, wet packs and the like, for their effect upon the general health. In most cases also a daily massage is given to stimulate the muscles. When these measures, which usually suffice, fail, recourse is had to cathartics: in the event of these too proving inadequate, protein therapy (injection of 1-6 c.c. boiled milk) has in some cases produced further loss of weight. The cure should not be forced too rapidly; due regard should be paid to the patient's comfort and endurance. Upon discharge all patients should be instructed how to order their habits to prevent a return of obesity.-Schweizerische medizinische Wochenschrift, April 22, 1933.

Transitory Arthritis of the Hip-Joint in Childhood.—Richard W. Butler emphasizes the desirability of an early and exact diagnosis of arthritis of the hip in childhood. From time to time children are seen with the classical signs of arthritis, but with a history of only a few days' trouble, no signs of general illness, and a normal x-ray appearance of the joint. These children must be carefully observed for the possibility of an early tuberculous infection. Of 97 cases studied at St. Thomas' Hospital 50 proved to be tuberculous, while 34 were suffering from a transitory arthritis only. Seven had a transitory arthritis

as a reaction to a localized bone infection near the joint, without true joint infection. analysis of these cases with reference to their origin indicates that although the condition may sometimes be traumatic in origin, it is more often infective, being frequently secondary to a focus elsewhere in the body. The prognosis of this transitory arthritis is excellent. A follow-up of 22 cases for an average period of three years showed that there had been no return of symptoms in 19. Of the other three children two had hysterical contracture of the hip and one had congenital syphilis. The inclusion of these children shows the type of mistake that may arise if one accepts too lightly a diagnosis of tuberculosis. A transitory arthritis is most difficult to differentiate from tuberculous arthritis of the hip in childhood. Clinically the two may be identical and remain so for days or even weeks. The x-ray is negative in a transitory arthritis except in the type due to a well-defined neighboring bone focus—but a negative x-ray does not absolutely exclude tuberculosis. As a matter of fact, however, the x-ray is seldom negative in tuberculous arthritis when the child is first brought for examination. Of the fifty-six children in this series coming under treatment for early tuberculous arthritis of the hip there was only one in which the x-ray picture was absolutely negative. The differentiation of transitory arthritis from pyemic joint and from pseudocoxalgia seldom gives rise to difficulty. All doubtful cases of arthritis in childhood must be watched carefully and treated with the respect due to an arthritis that is likely to be progressive. Time alone will then solve all doubts of the diagnosis.-British Medical Journal, June 3, 1933, i, 3778.

The Influence of Puberty Upon the Color of the Eyes.—All colored tissues of the body -skin, hair, iris-undergo changes of coloration at puberty, says Paul Godin. A close study of the iris reveals in fully 50 per cent of individuals the existence of two zones, an internal one immediately adjoining the pupil and an external one surrounding the former. It is the latter which gives the eye its predominant color. Eyes in which the two zones are not easily recognizable are especially those of a very dark brown color. The evolution of the color of the eyes is shown," at the beginning of puberty by a "brightening" of the original color. The most striking changes concern the tint, the combination of colors and the arrangement by which two or more colors seem to be juxtaposed or superimposed, sometimes similarly in the two zones, sometimes differently, taking the form of stripes, spots, specks, or dots in the external zone, and of rays in the internal one, designed upon the background by means of 1 or 2 colors. Variations have been observed, where qualified colors appear-brownish, greenish, yellowish. In the course of the four years from the age of 131/2 to 171/2 the intermediary colors, while departing little from the coloratious of the background or from that of the superimposed colors, do not follow a regular progression toward the final color, and seem to escape any fixed rule. The author's 100 cases, in each of which observations were taken nine times, at half-yearly intervals, between the ages of 13 and 18, constitute the basis for the construction of a scale of iris colors, taking into account their infinitely varied combinations and changes during this period An understanding of the oculochromatic evolution of puberty will save the expert the embarrassment which he might experience upon establishing at the age of 17 a different color of the eyes from that which he noted in the same subject at the age of 15 In cases of retarded puberty, changes in the color of the pig ment of the iris are more numerous Oculochro matic stabilization, 10, the definite color of the eyes, is accomplished when puberty has become fully established, or about two years after it began. The observations revealed no difference between the two sexes in respect to this behavior of the iris -Bulletin de l'Academie de Médecine, May 9, 1933

Treatment of Acute Coryza by Autogenous Vaccines -The object of this study was to determine whether autogenous vaccines were of any greater value than stock vaccines in the treatment of coryza In previous studies Hoyle found that individuals who suffered from unusually frequent and severe attacks of coryza harbored pneumo cocci, influenza bacilli, and "mouse pathogenic green streptococci" in large numbers, these organisms showing an increased incidence during infections Hemolytic streptococci and Fried lander's bacilli were present in some cases view of these findings all vaccines employed contained pneumococci, influenza bacilli, and the mouse pathogenic green streptococci," and, if an autogenous strain were not available a stock strain was included Hemolytic streptococci and Fried lander's bacilli were included in the vaccine only when autogenous strains were available seven patients with frequent and severe attacks of coryza were treated by autogenous vaccines, with the result that in 28 cases there was no benefit whatever, in 23 cases the severity of the attacks was reduced, but not the frequency, while in 16 cases there was a reduction in both the severity and frequency of the attacks. These results indicate that autogenous anticatarrhal vaccines, like stock vaccines, do not appreciably affect the incidence of attacks of acute coryza, although in some instances the attacks were less severe, but the benefit, in the author's opinion, was not sufficient to justify any very extensive use of such vaccines The suggestion has been made by previous workers that while stock anticatarrhal vaccines have no effect on the incidence of acute

eoryza, they tend to diminish the frequency of severe complications such as pneumonia, this suggestion has been supported by a small number of cases treated by autogenous vaccines.—British Medical Journal, June 10, 1933, 1, 3779

A Newly Discovered Danger to Smokers — Neumann-Wender states that in the course of many years' study of the effects of tobacco he has become convinced that, in addition to nicotine, other ingredients of a harmful nature are present in smoking tobacco. Among these is a tar that forms in the process of smoking The greater the amount of woody portions of the leaf incorporated in the manufactured product, the greater is the amount of tar delivered in the course of smoking, to be retained in the capillaries of the lungs upon inhalation. These woody portions are present especially in the ribs and nerves of the leaves, and it is these that give occasion to tar formation condensed smoke, along with volatile acids, the author has also found methyl alcoholan experience confirmed by certain other writers Through determination of the amount of methyl alcohol it has been found possible to determine the content in lignin of the hard ened cellulose and the degree of "lignifying" Neuberg and Ottenstein found that a smoker who smokes 10 medium size cigars a day con sumes in round figures 70 gm tobaeco containing 42 mg methyl alcohol, a eigarette smoker consuming 20 cigarettes a day inhales about 40 mg methyl alcohol. Although these small amounts are not in themselves poisonous, one must not forget that the action of methyl alcohol is cumulative, and that its absorption over a period of years may possibly be the cause of the disturbances of vision ob served in confirmed smokers. It is evident that with an increased use of the lignified ribs a larger amount of methyl alcohol is given off in the process of smoking At the present time these hard, woody ribs are being adapted to use by means of special machines that roll cut or dissolve them into fibers, after which they are sold to eigar manufacturers in more or less considerable amounts. When this manipulation was but little resorted to, the danger was relatively slight, but the use of ribs has so greatly increased of late that the supply of the home product in Germany has proved madequate, and ribs are now being imported from foreign countries From 3,528 dozen ribs imported in 1927 the number has risen in 1932 to 76 637 dozen This enormous increase in the smoking of ribs is certainly not above suspicion Since these contain neither incotine nor aromatic substances, and give off harmful substances when burned they must be regarded as inferior waste products - Münchener medizinische Wochenschrift, May 12, 1933

LEGAL

MALPRACTICE—RECENT NEW YORK DECISION EXONERATING PHYSICIAN

By Lorenz J. Brosnan, Esq.

Counsel, Medical Society of the State of New York.

The opinion of a distinguished judge in which he exonerated a physician of charges of malpractice in an action recently tried by your Counsel's office, is, we believe, worthy of discussion in these columns. The case was one which arose out of a series of treatments for a glandular disorder suffered by a young woman about thirty-five years of age. At the time the doctor was first consulted the patient complained of an itching condition of the skin of a number of months duration. The patient remained under the doctor's care and he examined her and prescribed for her condition from time to time over a period of nearly nine months. During part of that time she was under the doctor's care, confined to her bed When he last saw her, she was improved although not cured. The details of treatment and the facts surrounding the patient's condition are fully discussed in the court's opinion, to which reference will be made later in this

Within a few months after the patient was last seen by the doctor, she started a Supreme Court action against him, charging him with malpractice and seeking to recover \$25,000 damages. plaintiff's complaint, which was drawn in very general terms, stated that the defendant had been employed to attend her and cure her of a malady consisting of an itch of the genitalia, and that as a result of defendant's negligence she continued to be sick, nervous and disabled; that her health and constitution were injured, and that she was thereby prevented from attending to her vocation. The negligence charged by the complaint was that he prescribed improper medicines, pills, tablets and capsules for the plaintiff and failed to properly observe her condition from time to time.

A bill of particulars was served by the plaintiff's attorney in which it was particularly charged that the negligence of the defendant had consisted of prescribing excessive quantities of thyroid extract and in ordering the plaintiff to omit all carbo-hydrates and milk from her diet, and in failing to examine her at least once a month. The bill of particulars set forth her claimed injuries to include: an operation for subtotal extraction of the thyroid gland with a resultant scar, tremor of the hands and loss of weight. Special damages including medical and operative fees were claimed.

The case came on for trial before a judge sitting without a jury and after all the evidence had been put in on both sides, the judge directed a verdict in favor of the doctor. In his opinion the court summarized the testimony that was introduced so clearly and tersely that it is well to quote from the same nearly in full. The court said:

"The physician in this case, while he is a specialist in neurology, and specializes more particularly in certain branches of neurology, was not consulted as a specialist by this plaintiff. He does not claim to be, and did not hold himself out to be a specialist in endocrinology. The fee that he charged for his services was a very modest one. He did not charge the fee of a specialist. He charged the fee of a general practitioner.

"In an action of this kind two questions are presented.

"In an action of this kind two questions are presented. First, did the physician violate the duty which he owed the patient? And second, was his violation of duty, the competent, producing cause of the resulting injury claimed?

claimed?
"I have already outlined the duty which a physician owes to his patient. The question is whether that duty

has been violated in this case.

"Now, at the first examination of this plaintiff the doctor made the regular examination that would ordinarily be required in a case of the kind that he was considering. He arrived at a diagnosis; and, from all the testimony in this case there is not the slightest basis for finding that his diagnosis was unreasonable, because all the doctors that were called agreed that the skin affection from which the plaintiff was suffering, might be caused by a glandular condition.

be caused by a glandular condition.

"He prescribed at that time some thyro-ovarian extract. That contained a quarter of a grain of thyroid extract mixed with four grains of ovarian extract. He prescribed 100 tablets

prescribed 100 tablets.

"The patient followed that prescription. When she eame to the doctor her pulse was normal, her heart was normal, her respiration was normal. She took this prescription, and, according to her testimony, it produced no ill effects on her at all. Her condition was just the same, except, possibly, so far as her rash was concerned, after she took this first prescription.

"Of course, one might say that the doctor should have head a beauty at the doctor should have the doctor shou

"Of course, one might say that the doctor should have had a basal metabolie test before he gave any prescription at all. Well, that would be the height of prudence and caution, perhaps; but certainly such a high degree of prudence and eaution is not expected of a physician, and sometimes not desirable. The test itself involves a considerable amount of inconvenience to the patient, and a substantial fee has to be paid for it.

"However that may be, there were no ill effects at all in convenience of the patient, and

"However that may be, there were no ill effects at all in consequence of the prescription which the doctor gave at the time. The patient did not react unfavorably, nor did she show any sensitivity to the thyroid extract in that small amount. This medicine was designed to last for several weeks. The doctor put her on a diet because of the rash. That was a normal thing to have done.

Even a layman understands that.

"Now, on March 13th she came back again. Thus far there certainly is no evidence that the doctor acted in any other way that a conscientious, painstaking doctor would have acted under the circumstances of this case. Whether he was in error in his diagnosis certainly is not

for this court to say; because, assuming for the sake of argument that there was an error in the diagnosis, that would not be a basis for an action for malpractice, for if that were so we would soon have very few doctors left. And what would become of the lawyers and judges I hesitate to say.

"On March 13th the doctor thought that the rash was getting a little better. The tablets were stopped, and she was given a nerve scolative, and the doctor at that

time prudently advised that a basal metabolic test be lad.
"Then we come to the visit of April 17th. Up to that
time there was certainly nothing at all wrong in the
light of all the testimony in the case. Dr. G. (an expert
witness) said that the food had nothing to do with this
condition. I am referring to the restriction of the diet.

"Now, on April 17th the skin condition became worse; and, in view of the fact that the report of the basal metabolic test was on the fringe of normal—because it was either minus 10 or minus 12—the doclor in his judgment thought it wise to prescribe thyroid extract, one grain to be taken twice a day, or a total of two grains a day.

"Well, up to this point, the patient not having reacted unfavorably to the prior prescription (smaller in dosage, to be sure); the basal metabolic test being on the fringe, according to the testimony of everyone who appeared here, it cannot be said that the doctor did anything other than the customary and usual thing in prescribing this thyroid extract. Assuming, for the sake of argument, that here also there may have been an error in judgment, an action in malpractice cannot be based upon that course of treatment under the circumstances of this case.

"So we come to May 1st. And here again, although she had taken this thyroid extract for a period of two weeks, which time it may reasonably be assumed would be adequate to determine whether the patient was sensitive to this form of drug, she herself testified that there was no change in her general condition up to that time, and the doctor found no change. The skin condition was getting worse, however, and he changed the treatment there.

"Then we come to what I consider to be the most important factor in this case; namely, what took place between May 1st and June 18th, and we have a conflict in the testimony there.

"It can hardly be said that the doctor was guilty of malpractice in not having the patient call to see him oftener. He saw her two weeks after the thyroid extract treatment was commenced on May 1st. He found no ill effects. The patient herself experienced no ill effects.

"Now, of course, lindsight is always better than foresight; but it is pretty hard to hold a doctor for malpractice when he conscientiously gives the best advice of which he is capable and does not desire to put a patient to any more expense than is necessary in his opinion. A patient can always come to see the doctor whenever he or she desires. There is nothing at all to stop that. Moreover, there were no warning signals up to May 1st that would have put the doctor on guard and cause him to insist on more frequent visits. Besides that, the doctor did in this case what some physicians refuse to do. He would talk to the patient any time she desired over the telephone, and he did give his advice from time to time.

"On May 8th there was this telephone conversation which the plaintiff claims took place and which the doctor denies. In the light of all the circumstances in this case I must accept the doctor's version, because I feel, from the testimony in this case and based upon the doctor's experience and the way he acted throughout the entire case, if the doctor's attention had been called to the fact that there was a sharp increase in the rate of the heart-beat and the condition which the plaintiff claims that she was suffering from at about that time,

he would have done at that time what he did on June

"I do not believe that any action for malpractice can be based or should be based upon an alleged telephone conversation denied by the doctor and which does not appear to be reasonable and probable in the light of all the circumstances.

"The plaintiff claims that on May 8th the doctor told her to stop using the thyroid extract for a period of about three days, and then to resume it and to come to him again when she had finished. The doctor states that, as the skin condition became worse, and as the patient manifested considerable anxiety over that condition and attributed it to the pills which she was taking, he told her to stop for three days.

"Now, up to that time, if she had followed his prescription regularly, she should have taken about 40, at least, of these pills, and she should have come to him of her own accord before June 18th, assuming that the dose was reduced from two pills a day, or two tablets a day, to one a day. But, I find from the evidence in this case that up to June 18th the doctor was not guilty of any act of omission or any wrongful act on which an action

act of omission or any wrongful act on which an action for malpractice may be based.

"From June 18th until he ended his connection with the case the evidence is clear that the doctor acted in the eustomary and usual way. It is difficult to see what else he could have done under the circumstances. It is true that, from the evidence in the case, the Court is bound to come to the conclusion that the use of the prescription of thyroid extract was a producing or contributing factor in bringing about this hyper-thyroid condition; or, that it did aggravate a pre-existing, latent condition. That seems to be the inference that can fairly be drawn from the testinony in the case. But I don't see how it could be found that the doctor is in any way responsible therefor.

"After June 18th he at once stopped the thyroid extract. He did give some pituitary gland extract. Whether that was proper under the circumstances is another matter of judgment. Even Dr. G.— (the expert witness), however, said that the use of pituitary gland extract, although he did not think it was proper, had nothing to do with what developed here.

"The rest, the change in the prescription, were all customary and usual methods of treatment.

"There is a dispute as to whether or not there was a change made in the dict, and when it was made. But it is unnecessary to go into that because certainly, if the plaintiff claims that the doctor told her that he had made a mistake in depriving her of these things, that she should have had these articles of food, it is most reasonable to assume that he told her that she could have them from that time on. It is rather far-fetched to assume that he would tell her that, and at the same time either tell her to continue the old diet or remain silent about it. But, further than that, Dr. G— (expert witness) testified that the diet would have nothing to do with the development of the condition of hyperthyroidism which manifested itself."

In coming to his conclusion the court stated his summary of the law applicable as follows:

"A physician is not an insurer. He is not held to guarantee the success of his treatment. His duty is defined in the leading case of Pike v. Honsinger, as follows: 'Upon consenting to treat a patient, it becomes his duty to use reasonable care and diligence in the excrise of his skill and the application of his learning to accomplish the purpose for which he was employed. He is under the further obligation to use his best judgment in exercising his skill and applying his knowledge. The law holds him liable for an injury to his patient resulting from want of the requisite knowledge and skill, or the omission to exercise reasonable care, or the failure to use his best judgment. The rule in relation to learn-

ing and skill does not require the surgeon to possess that extraordinary learning and skill which belong only to a few men of rare endowments, but such as is possessed by the average member of the medical profession in good standing. Still, he is bound to keep abreast of the times and a departure from approved methods and general use, if it injures the patient, will render him liable, however good his intentions may have been.' The plaintiff cannot succeed merely by establishing that the physician was guilty of a mistake of judgment. 'The rule requiring him to use his best judgment does not hold him liable for a mere error of judgment, provided he does what he thinks is best after careful examination.'"

The case so quoted from by the court has been for years the leading authority in this State as to the law governing the liability of physicians for malpractice.

In applying the law to the facts of the case, and in concluding that in the light of all the circumstances the plaintiff had failed to establish her case, the court said:

"Of course there are differences of opinion as to what treatments should be given by physicians under certain circumstances, just as there are differences of opinion among lawyers as to the course of action to be pursued in a litigation, or in any controversy that comes up. In this case, taking the testimony of the doctors called on behalf of the plaintiff, there was a difference of opinion as to what treatment should be given. Dr. G— (expert witness) thought that an immediate operation, or, at least, an operation would be necessary, and he gave a certain treatment. Dr. P— (an expert witness) at first thought that an operation would not be necessary, and he followed a different method of treatment. It seems to me it would be going entirely too far and beyond the bounds of reason to say that either one, or both, of these physicians was guilty of malpractice because a mistake may have been made. So it would be going beyond the bounds of reason to hold that because unfortunately a post-operative pneumonia developed there was something wrong with the doctor who performed the operation or who administered the anesthetic.

"Mistakes will happen. There is no question about

"Mistakes will happen. There is no question about that. The best of physicians, the best of lawyers, the foremost experts in every line of endeavor, will make mistakes from time to time. The law does not hold that simply because an honest mistake or an error of judgment has been made that the person who makes it shall be guilty of malpractice."

It is interesting to note that in the last analysis this case hinged on lay testimony. In nearly every

malpractice case we have ever tried or handled there is testimony by the patient and her relatives seeking to establish negligence on the part of the physician. The decision on these sharply contested questions of fact is often determinative of the action. It is heartening to note that in this opinion the court rejected the testimony of the patient, and accepted the testimony of the physician, as to what transpired during a certain telephone conversation in which the plaintiff claimed to have told the doctor of certain symptoms which, concededly, if he were told, would have put him on notice that the treatment should be changed. This telephone conversation was categorically denied by the doctor. As the court said in determining this important question of fact:

"In the light of all the circumstances in this case I must accept the doctor's version, because I feel, from the testimony in this case and based upon the doctor's experience and the way he acted throughout the entire case, if the doctor's attention had been called to the fact that there was a sharp increase in the rate of the heart-beat and the condition which the plaintiff claims that she was suffering from at about that time, he would have done at that time what he did on June 18th."

In the course of your Counsel's experience in the handling of malpractice cases, which covers a period of about fifteen years, we have never read any decision from any court which displayed a more comprehensive and understanding point of view toward the practice of medicine. The judge who wrote this decision is one of the ablest judges in the State of New York. He is not only able but he is fearless, and his opinions are respected by his colleagues. Particularly do we wish to call attention to that part of the opinion in which the court says:

"Whether he (the doctor) was in error in his diagnosis certainly is not for this court to say; because, assuming for the sake of argument that here was an error in the diagnosis, that would not be a basis for an action for malpractice, for if that were so we would soon have very few doctors left. And what would become of the lawyers and judges I hesitate to say."

We feel sure that this learned opinion will be of great value as a precedent in malpractice cases.

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

The regular monthly meeting of the Committee on Public Relations of the Medical Society of the State of New York was held in the Albany office of the Society on Monday, June 26, 1933, holding an all-day session lasting from 10:30 a.m. until 5 p.m. There were present Dr. Sadlier, Chairman, and Drs. Mitchell, Hambrook, Cunningham and Ross. There were also present Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education, and Dr I. S. Lawrence, Executive officer.

Veneral Disease Clinics: A discussion of Venereal Disease clinics, which was begun in the meeting of May 29 (Journal, July 1, page 838), was continued with Dr. Parran, State Commissioner of Health present. The discussion was an informational conference which resulted in a clarification of the relations of the practicing physicians to the State Department of Health.

Blood Donors: The listing and control of professional blood donors was considered, and regulations similar to those in Greater New York were proposed. The subject will require investigation before action can be taken.

Crippled Children: The discussion of the care of erippled children, which was begun in the May meeting, was continued, but a decision was deferred until further information is obtained.

Examination of School Children: The subject of the physical examination of school children in Homer, Cortland County, which was considered in the May meeting of the Committee (Journal, July 1, page 838), was continued. The following explanation by Dr. D. R. Reilly, Conmissioner of Health of Cortland County, was read:

"The follow-up work on discovered defects in school children is one of the activities of this Department. We do not have sufficient funds, however, to permit us to undertake the actual correction of the defects. We attempt to have the parents concerned undertake the correction through their own physicians. Eye defects and dental defects we are able to correct through the generosity of some organization, such as Rotary. Of conrse, only a few are taken care of in this fashion. The Board of Education in Cortland employs a part time dentist, while Homer had available only about \$50.00 for dental work. Tonsil cases are taken care of for a nominal fee (\$2.00) which is provided by the parents.

"With a sufficient number of nurses this Department would carry on a satisfactory school program in all parts of the country, as well as in Homer. To do this in conjunction with our other

activities would require about six nurses. We have three. The only alternative scents to be the employment of school nurses by the local Boards of Education. Since there are at least four communities which would require school nurses the net cost would be somewhat greater.

"Even then the correction of defects would depend on the willingness of Boards of Education to provide funds for the payment of physicians or on the willingness of physicians to contribute all or part of their services."

It was the opinion of the Committee that Cortland County should not be singled out for comment, for the problem of discovering and correcting the defects of school children is universal, and Cortland County is putting its limited means to excellent use.

The Hard of Heoring: The Committee resumed a discussion of "The Hard of Hearing," which was reported in the July first Journal, page 838, and listened to a presentation of the subject by Dr. Emily A Pratt of the State Department of Education, and Miss Estelle E. Samuelson, of the New York League for the Hard of Hearing, 480 Lexington Avenue, New York City. The speakers developed the following argument for action.

From four to ten per cent of school children show some degree of hearing defect.

Facilities are not adequate for dealing with the defects.

Otological examinations are difficult to obtain without the payment of a fee.

Children arc committed to institutions for the hard of hearing on insufficient evidence—sometimes of physicians, sometimes of dentists, and sometimes of laymen.

About 150 children are committed to the institutions annually.

The children in the institutions do not receive adequate attention in regard to their fears, because there is no money to pay otologists, and no otologists are on the staffs.

Deafness has been excluded as a condition to be treated under the crippled children's law.

The speakers summarized the situation as follows:

"There are schools for the deaf, absence of otological service, no available list of otologists who could be called upon, and no provision for fees for them. There are two situations—one in the public schools of the state which is reasonably well handled; and the other in the schools for the hard of hearing which is not well handled.

"In New York City the otologists ecoperate in

solving this problem. In the State the problem is not well met and the real question is, shall it be solved under the direction of the State Medical Society or under the direction of the League of the Hard of Hearing? It came to the surface that the State of New York pays \$600 per year for each child in the schools for the hard of hearing. It was stated that the State Department of Education would welcome an investigation regarding medical care of the hard of hearing in these schools, and would receive kindly suggestions as to how the problem could be met.

"An increased use of the audiometer in 45 places shows that there are 210,547 children in 45 different places having some defect in hearing; that 88 nurses are made use of in the care of

these children; that there are 45,000 children in the state needing lip reading training. It was believed that clinics could not do all the work if that method was tried."

In the opinion of the committee the problem is a greater one than has been thought; that the profession of medicine has before it another problem of great importance; and that the profession should assume responsibility for working it out. The whole matter was placed in the hands of a. sub-committee made up of Dr. Hambrook of the Committee on Public Relations and Dr. H. M. Atkinson of Catskill representing the Committee on Public Health. This committee was asked to report at the next meeting of the Committee on Public Relations. W. H. Ross, Secretary.

COMMITTEE ON TEMPORARY EMERGENCY RELIEF ADMINISTRATION

At a contact meeting held July 14th, a number of very satisfactory reports were received from County Societies as to the working of this Law.

Where the County Contact Committee has met with the Welfare Officer, or Officers, of the County, in almost all instances a satisfactory agreement has been reached. In some cases the factor of allowed mileage has yet to be established, and some vouchers are being sent back by the Comptroller's office to the Welfare Officer because Section 4 of the Agreement has not been complied with. This Section reads as follows:

"Each bill shall be chronologically arranged and state the name, age, and address of the patient; the diagnosis; or (italics are editorial) the general indication of the entire illness; the nature of the treatment, i.e., in home, office, or special type of care; the dates on which service was rendered; and the status of the case at the end of the month (cured, sent to the Hospital, needs turther treatment, dead). Bills for medical care shall be accompanied by the original written authorization for such care."

It is absolutely necessary to have these facts, else the Contact Committee in your County Society—or higher up in your State Society—cannot pass satisfactorily on the bill and decide whether it is in ordinary routine or comes under the clause of special work.

It has been found that few of the County Society Contact Committees are supplied with:

1. The Public Welfare Law—issued by The State Department of Social Welfare—State Office Building, Albany, N. Y.

2. The Public Health Law—issued by The State Department of Health—State Office Build-

ing, Albany, N. Y.
3. The Emergency Unemployment Relief Laws in the State of New York, issued and published jointly by the Temporary Emergency Relief Administration, and the Attorney General's Office of the State of New York.

With these three pamphlets many grievances can be immediately settled by the County Society through its Contact Committee, in cooperation with the Welfare Officer.

Each month has recorded larger and larger sums of money being paid by Welfare Officers to the medical fraternity, general practitioners and specialists sharing in this outlay.

The doctors are doing their share and more at present; but are receiving more income as their work increases, where the agreement is in force.

Some Welfare Officers are paying much more for services than is allowed them on the percentage return from the TERA, thus showing their own and the community's desire to pay for services rendered.

Some Welfare Officers have tried to save money for their taxpayers by themselves giving orders for proprietary drugs, through the advice and suggestions of certain nurses. This type of medical practice immediately runs up against that clause in the agreement which forbids of such prescribing, save on the special order of the Welfare Officer to a physician; for the Welfare Officer cannot get his money back from the TERA for such an expenditure made under such conditions.

In cases of specialists being called, an increasing number of local consultations are being held by authorization of the local Welfare Officer, thus keeping the patient within the attending physician's hands. In most instances where a patient goes to a Hospital, (a) The Hospital loses money because of a reduced rate agreement "in the interest of charity"; (b) The physician "back home" receives nothing and his patient has been "lifted"; (c) while in most instances, at present, the hospital attendant, medical or surgical receives not even a thank you.

It would seem that the County Fee Bill is becoming the individual county basis at which the local county physicians evaluate their minimum (cost?) charges for services, and many Welfare Officers now are paying the physician in accordance with the fee schedule of the community

There are still some counties which must adjust their nuleage with the local Welfare Officers, as well as the question of multiple calls in one

family at the same visit

Home relief for Veterans is now under the TERA, thus simplifying this class of cases, orders for treatment coming from the Welfare Officer, and bills with vouchers being sent him for payment

Some counties have not yet used funds of the TERA, so your committee cannot tell if doctors in these counties are receiving their just recompense for services to the indigent

Many physicians are learning that a number of their charity cases on their books should be paid

for by the local Welfare Officer

There have been a few solitary instances where physicians have not been in agreement with their County Society, and with the Welfare Officer, and have charged more than the fees arranged between the Society and Welfare Officer some of these cases, it would appear that the doctor was entitled to his fee charge rendered and had made a sufficiently clear explanation, but the Welfare Officer had not had the benefit of dis cussion with the local County Society Contact Committee, or there was disagreement between them that needed enlightening of both sides

Statistics show that in February, 1933, of the total expenditure of TERA funds in the entire State, outside of Greater New York and the large cities, 49 per cent was paid under the head of medical services In May this proportion had

risen to 75 per cent

Your State Contact Committee now has the figures for amounts expended for each County

up to date for medical services

To determine the propriety of disputed bills, rendered under the 'Special Service' Clause of the Agreement, your Committee is still at a loss until each County Society files its fee bill with

your Contact Committee, with Dr H J Davis of the TERA, and with the County or Local Welfare Officer Most of the Welfare Officers do not yet know what the minimum charges are from their local County Medical Society, hence arise some of the controversies

The question of reimbursement for drugs should also be settled locally, for the TERA only reimburses the Welfare Officer up to 75 eents for a prescription, which should be of the simple drugs, unless authorized in writing to ex pend more, by the Welfare Officer or the local Contact Committee of the County Society

Attention is again called to Article "C" which is not being applied as extensively as it should

"1-The Medical Society of the State of New York has agreed to request each County Medical Society to appoint or designate a Committee to advise, at least monthly, with the Local Welfare Official"

'The Local Welfare Official shall consult this Committee concerning problems of medical care,

such as

(a) The reasonableness of any given bill for medical services

(b) To investigate complaints made with regard to medical care

(e) Any proposed change in policy with regard to provision of medical care

(d) Principles to be followed in the alloca-

tion of cases to physicians"

'In addition this Committee will be asked to communicate to the TERA failure of any local Welfare Official to authorize reasonably required medical care "

2-Local Welfare Officials are requested to re port to the Medical Director of the TERA failure of the local Committee of the County Medical Society to cooperate in the provision of reasonable niedical care to Welfare cases'

> JAMES N VANDLE VELE Chairman. HYZFR W JONES ALBERT G SWITT

FIREWORKS IN SYRACUSE

The passage of an ordinance forbidding the sale of fireworks in the City of Syracuse as reported in this Journal of August 15, 1932, page 982, has been effective in preventing accidents from Fourth of July fireworks Dr D T Gillette writes

We are fortunate in Syracuse in having an

ordinance passed banishing the sale and use of fireworks within the city limits. The police department has adequately enforced this law, with the result that there were no injuries due to the use of explosives on the Fourth of July This is a very excellent example for other communities '

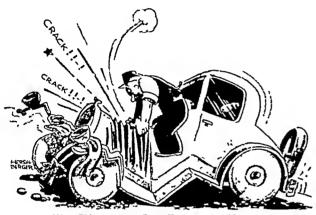

THE DAILY PRESS

HOME TELEPHONE RATES FOR CHIROPRACTORS

The New York Herald Tribune of July 13 contains an account of a plea made before the Public Service Commission by chiropractors and chiropodists that they be allowed home

The Chiropractor Gets Engine Trouble -From Judge, July, 1933.

rates for the telephones just as physicians are. The account says:

"Residential rates now apply to office telephones in the homes of physicians, surgeons,

dentists, osteopaths, Christian Science practioners, veterinarians and nurses, according to a schedule of the telephone company.

"The company called Arthur D. Welch assistant vice-president of the New York Telephone Company, who said that he had charge of rates, practices and commercial co-ordination in the city area. Mr. Welch said that the present rates had been in effect since 1910 and that the only reason the company had ever allowed a lower rate to professional men was that it had assumed that their possession of home telephones would be an inducement to other persons to buy telephone service.

"I see no reason why any profession should be accorded this preferential privilege," Mr. Welch kept repeating throughout the hearing.

"Mr. Welch said he believed that even the present rate schedule was discriminatory. He said that surveys showed that professional men with telephones in their homes made as many out-going calls as a small business firm and received a great many incoming calls. In his opinion these incoming calls were largely of a professional or business nature, yet the rate paid was based on residential use."

IS CANCER HEREDITARY?

The New Jork *Times* of July 18th asks the question "Is Cancer Hereditary?" and then presents the evidence of the nature of cancer in the following excellent editorial:

"A large and important school of European and American biologists has for years been collecting evidence from family histories and life insurance statistics to support the hypothesis that cancer is an inheritable disease, Much to be preferred are deductions from laboratory experiments under strict control. It is precisely this method that Dr. Maud Slye of the University of Chicago has been applying in cancer studies which are now regarded as classic here and abroad. For twentythree years she has been experimenting with mice of known strains. The number of her post-mortems (116,000) is so large that her results cannot be questioned on the score of inadequate material. Hence her view that susceptibility to cancer may be an inherited characteristic must be received with the utmost respect. We deal with genes—invisible units which are to the cells what atoms are to ordinary matter. If we could only control the manner in which genes are linked (the possible combinations are almost infinite in number), it would be possible to control not only cancer but the whole human organism. But Dr. Slye is careful to state in her article, which appears in *The American Journal* of Cancer, that more than an inherited susceptibility is probably involved. An external factor acting with internal factors upon susceptible soil is probably the cause of cancer.

"When we turn to the findings published earlier in the year by Drs. M. R. Curtis, W. F. Dunning and F. D. Bullock of Columbia we seem to reach a different conclusion. For twelve years they bred not mice but rats, white and colored, and infested them with a parasite known to produce cancer of the liver. All told, 52,000 animals were studied. Of these half were controls; of the treated remainder,

only 3,300 developed cancer. There was no evidence that liability to the disease is borne in the genes and is therefore hereditary. No matter how inbred the animals were, the liver was affected only when the parasite was introduced. Chance alone decided whether eancer was to result—the chance of long life. Cancer is chiefly a disease of the aged.

"Although two sets of experiments apparently lead to different conclusions, there is in reality no conflict. Dr. Slye deals with spontaneously generated tumors; Drs. Bullock, Curtis and Dunning with tumors that are the result of deliberate irritation. Moreover, mice

and rats differ in their susceptibilities. It is strange yet true that a parasite which will cause a sarcoma of the liver in a rat will not cause it in a mouse. In both sets of experiments it is Dr. Slye's external factor, whatever that may be, which is the direct cause of disease.

"The problem of cancer is the problem of life, because it is a problem of the cell. Some marked and constant difference between cancer and normal tissue must be discovered, and it is to the making of such a discovery that Dr. Slye and Drs. Curtis, Bullock and Dunning have contributed so notably by their experiments."

THERAPEUTICS OF MISCHIEF

It seems strange to hear mischievous fun prescribed as a help to success, but this advice was seriously given by an eminent authority, according to the following news item from Chicago in the New York Herald Tribune of July 13:

"Speaking tonight at the authors' dinner given by the National Federation of Business and Professional Women's Clubs in convention here, Miss Catherine Oglesby, associate editor of 'The Ladies Home Journal,' declared that the only real purpose of leisure was to use it unwisely, and that the true reason for working wisely from 9 to 5 is to enable people to play foolishly the rest of the time.' The right use of Leisure' was also discussed

by Mrs Frances Parkinson Keyes, of the staff of 'Goodhousekeeping,' and by Mary Synon, Chicago, writer and traveler.

"Wisc work and foolish play is a sure means of success," said Miss Oglesby. "Every business woman when making up her budget should have on it the item of extravagance and in making up her time schedule should allow a period of mischief, What goes for boys goes for girls, and the good things of life seldom fall to the lot of the dull Jills.

"In fact, psychologists who have studied women in business declare that most women fail to advance because they don't know how to play. For this reason I commend mischief to you."

DIGESTION BY MR. ROBOT

The New York Sun of July 13 describes some of the visual demonstrations of chemistry at the Chicago World's Fair, including the production of sulphur, oil refining, the manufacture of rubber, and the effects of liquid air. The article concludes:

"The final story is on the chemistry of food and nutrition. This exhibit is unique. A tenfoot robot will give a twenty-minute lecture on food chemistry and nutrition, illustrating it by demonstrations which he operates, a number of static exhibits to which he points, and finally the demonstration of the processes of digestion on himself by means of a moving picture projected from behind on his own front. The robot describes the constituents of food. He demonstrates the function of each and how they are broken down or digested in the body tissues. He also describes the functions of the hormones or chemical messengers."

BACTERIOPHAGES

Any person who reads the more serious parts of the daily papers will gain a knowledge of many points of medicine. The editorial columns of the New York Timec of July 7 discusses bacteriophages in a truthful, balanced way, taking as its text the reports that the New York Aquarium was besieged with applicants for bacteriophages for skin eruptions following a news item that worknen in the Aquarium were cured of sore lands by working in the water. After de-

scribing bacteriophages the editorial concludes:
"Medicine and bacteriology stand upon the
threshold of an advance as great as any ever
made. In the past a student of infections dealt
with what he could see. Now the world of the
unseen lures. Opportunity beckons to a new

with what he could see. Now the world of the unseen lines. Opportunity beckons to a new Pasteur who will reconcile conflicting theories and observations, even as the old pasteud did, and give us exact technical knowledge where now there is only surmising, regarding the causes.

BOOKS RECEIVED

- Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.
- DIET IN SINUS INFECTIONS AND COLDS. By Egon V. Ullmann, M.D. Octavo of 166 pages. New York, The Macmillan Company, 1933. Cloth, \$2.00.
- GASTRIC ANACIDITY. Its Relations to Disease. By ARTHUR L. BLOOMFIELD, M.D. and W. Scott POLLAND, M.D. Octavo of 188 pages. New York, The Macmillan Company, 1933. Cloth, \$2.50.
- ARTERIOSCLEROSIS. A Survey of the Problem. A publication of the Josiah Macy, Jr. Foundation. Edited by EDMUND V. COWDRY. Octavo of 617 pages, illustrated. New York, The Macmillan Company, 1933. Cloth, \$5.00.
- THE SCIENCE OF HUMAN REPRODUCTION. Biological Aspects of Sex. By H. M. Parshley, Sc.D. Octavo of 319 pages, illustrated. New York, W. W. Norton & Company, Inc., [c. 1933.] Cloth, \$3.50.
- SENILE CATARACT. Methods of Operating. Second Edition. By W. A. Fisher, M.D. 12mo. of 267 pages, illustrated. Chicago, Chicago, Eye, Ear, Nose and Throat College, [c. 1933.]
- URINE AND URINALYSIS. By Louis Gershenfeld, Ph.M. 12mo. of 272 pages, illustrated. Philadelphia, Lea & Febiger, 1933.

- THE MEDICAL CLINICS OF NORTH AMERICA. Volume 17, No. 1, July, 1933. (New York Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net; Paper, \$12.00 net.
- HISTOPATHOLOGY OF THE PERIPHERAL AND CENTRAL NERVOUS SYSTEMS. By GEORGE B. HASSIN, M.D. Octavo of 491 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$6.00.

BOOK REVIEWS

Some Factors in the Localisation of Disease in the Body. By Harold Burrows, C.D. Octavo of 299 pages, illustrated. Baltimore, Williams & Wilkins Company (William Wood & Company), 1932. Cloth, \$4.50.

This volume deals with an attempt to explain the mechanism of the localisation of disease processes, including those caused by foreign proteins, syphilis, bacteria, viruses and cancer. It includes alsn a discussion of the factors that influence localization as well as some therapeutic considerations. It is based almost entirely on the results of personal research in the field of localization of cancer. The book is written in a lucid style, and well worth reading.

MAX LEDERER.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1932. Chicago, The Year Book Publishers, [c. 1933]. Pediatrics. Edited by Isaac A. Abr, M.D. 12mo. of 564 pages, illustrated. Cloth, \$2,25.

The practice of pediatrics as a specialty is but twenty-five years old and it is changing rapidly. New diagnostic and therapeutic procedures are being recorded constantly and the text books can scarcely keep pace with the progress. One must turn to the current pediatric journals for up-to-date information. It is expensive and time-consuming to wade through all the periodicals, but in this little volume one finds concise, meaty articles gleaned from the medical journals of 1932, boiled down for rapid assimilation. The Year Book Series lave always enjoyed popularity and this 1932 edition affords an easy and inexpensive method of brushing up on this specialty.

DAYID EDWARD OVERTON.

THE PRACTICAL MEDICINE SERIES, Comprising Eight Volumes on the Year's Progress in Medicine and Surgery, Series 1932. The Eye, Edited by E. V. L. BROWN, M.D., and LOUIS BOTHMAN, M.D. The Ear, Nose and Throat. Edited by George E. SHAMBAUGH, M.D., and ELMER W. HAGENS, M.D. 12mo. of 686 pages, illustrated, Chicago, The Year Book Publishers, [c. 1932]. Cloth, \$2.50.

Again this meaty little volume comes to hand for our permeal in leisure hours that we may keep abreast of the times with a minimum of effort. While every original bit of work put forth in the year is not summarized, the selections are in general well chosen. The editorial comments—with certain of the abstracts—are interesting, but the reviewer feels that it is not fair for the editors of such a work to sanction or disparage careful study with no more than a phrase or two. Such notes would better be omitted. While this work cannot be considered as a substitute for the abstract departments of the various journals, it is supplementary and is a very useful work.

John N. Evans.

THE 1932 YEAR BOOK OF RADIOLOGY, Diagnosis, Edited by CHARLES A. WATERS, M.D. Therapeutics, Edited by IRA I. KAPLAN, M.D. Octavo of 750 pages, illustrated. Chicago, The Year Book Publishers, [c. 1932]. Cloth, \$6.00.

This is the first attempt to present a Year Book of Radiology and Is of the same high quality as the other Year Books that have been issued of various branches of medicine. The well-known ability of Dr. Charles A. Waters of Baltimore and Dr. Ira I. Kaplan of New York in their specialties ensure the high standing of the

work. This is a presentation of the developments of the year 1932 in radiology—diagnostically and therapeutically.

The articles which have been selected for abstract are without exception of particular interest and value to the radiologist in keeping him abreast of the times in his specialty. The abstracting is extremely well done and the editorial comments on many of the subjects are very appropriate.

The section devoted to the Osseous System is extremely valuable. The authors have performed a useful function in selecting some articles which provide a timely word of warning. The articles on "lipiodol" are esperime. The clearness of the bedguards especially

make the bookwork especially most commendable for its

completeness.

This volume should be in the hands of everyone attempting radiology in any form, Charles Eastmono,

VARICOSE VEINS AND HAEMORRHOIDS AND THEIR TREAT-MENT. By V. MEISEN, M.D. Octavo of 149 pages, illustrated. New York, Oxford University Press, 1932.

This treatise is a monograph of 150 pages translated from the Danish into the English by Hans Andersen.

The author has had an extensive experience in the treatment of varicostics. He reports some 3,500 cases treated without fatalities.

He begins with the consideration of the anatomy and the physiology of the veins of the lower extremities. He next gives a complete description of the pathological aspects of varicose veins—then follows a careful consideration of the operative treatment and the injection treatment of the lesions.

The technique which he finally employs, as the result of his experience, has been repeated many times in American medical literature and does not need to be reviewed here. His conclusions are conservative and not too optimistic. His percentage of recurrences is rather low when compared with other figures.

Following the varicose therapy, the author considers the treatment of several allied conditions; such as, Angioma, Varicoccle, Hygroma, and finally Haemorrhoids.

Although this entire monograph contains nothing that is really new, its value lies in the fact that it gives the conclusions of a man who has had a vast experience in his chosen work.

ROBERT F. BARDER.

A LABORATORY MANUAL OF PHYSIOLOGICAL CHEMISTRY. By D. WRIGHT WILSON, M.S., Ph.D. Second Edition. Octavo of 284 pages. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$2.50.

This book is designed for use with a class. It starts with a page of general instructions on the manner of handling the various reagents and then proceeds with carefully selected experiments calculated to illustrate the essential chemical characteristics of the various substances dealt with.

The first part takes up the inorganic substances of physiological interest such as phosphorus, calcium, magnesium, sulphur, chloride and nitrogen. Then follow experiments on electrolytic dissociation and on colloids. The proteins, carbohydrates and fats are next dealt with.

The second part of the hook is devoted to the body tissues and fluids, concluding with directions on the conduct of metabolism studies and on dietary deficiencies.

The directions are brief and to the point. The text is printed on only one side of the page, leaving the other side blank for notes.

BENJAMIN DAVIDSON.

OUR NEIGHBORS

EXAMINATIONS FOR LICENSURE IN PENNSYLVANIA

The Pennsylvania Medical Journal for March prints the following letter from Irvin D. Metzger, Chairman of the Pennsylvania State Board of Medical Education and Licensure, regarding the date of taking the state medical examinations:

"The attention of the State Board of Medical Education and Licensure has been called to the notation of an implied criticism of the Board because it delays licensure by requiring a completion of the internship before admitting the candidates to the licensing examination. The suggestion was made that the examinations might be held a month or two before the close of the intern year, and the grades withheld until satisfactory certifications had been made of the completion of the same; thus the licensee might be in position to enter practice immediately.

"The law specifically asserts that the fifth or intern year shall have been completed before a candidate is admitted to the licensing examination. To do otherwise would mean to violate the law as it now stands; hence the suggestion is im-

practicable.

"In this legal requirement, as in many others, the Act as it stands, may be more sensible than the changes suggested. While the Board would be loath to extend the day of licensure an hour

further than necessary, it is infinitely more concerned in the legalizing of physicians that are worthy than in hastening the time for their gainful employment.

"The intern year is the one in which the young physician secures real training in the art of medicine. A calendar year is scant enough in which to unscramble his theoretic ideas and formulate for himself a sane philosophy of professional life. His contacts with successful clinicians are apt to stamp upon him the labels which will vouchsafe for him a similar career. That sublime sense of responsibility which marks not only the conduct and attitude of a real physician but which sets the seal of divine selection upon his brow, cannot be developed in a few months, especially when licensure is the paramount mental concern.

"Better to have each candidate for licensure earnestly concerned with the seriousness of the profession he is entering than with the immediate return of dividends on money invested. Service rendered in this spirit will be sought early and be compensated well. Merit in medicine as elsewhere always assures its own reward but cannot be attained in a minimum of time and in half-hearted service."

PRELIMINARY MEDICAL EDUCATION IN MASSACHUSETTS

The New England Journal of Medicine of April 6, contains the following editorial on the lack of preliminary educational requirements for studying medicine in Massachusetts.

"In medical legislation for the protection of the health of the people by the control of medical practice, Massachusetts has the distinction of standing alone—in one respect. There is such a thing as progress in medical legislation, and it is clear also that a medical school should not be allowed to carry on medical education irresponsive to the demands of medical science and practice, irrespective of the opinion of other schools, in entire independence of what other schools think or do. Such independent individuality, with only internal control, tends to loss of balance, lack of symmetry, disintegration of personality and degradation in social responsibility.

"In the control or lack of control over the

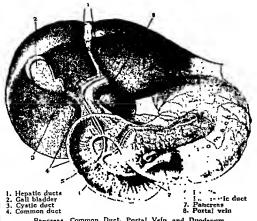

"In the control or lack of control over the medical education which the state requires of candidates who desire to enter the practice of medicine, Massachusetts stands—still—

and alone. All the other states have given their Boards of Registration in Medicine discretionary power of approval of medical schools from which they receive candidates for examination. In the course of years, the procession of other states and federal jurisdictions has filed by, some states many years ago. Colorado, the last of the other states, enacted this legislation six years ago; for the District of Columbia, the last of the Federal jurisdictions, it was enacted four years ago. But Massachusetts—there she stands—still—alone—refusing to enact this law for the protection of the health of the people of this Commonwealth.

"Justice Oliver Wendell Holmes has said: 'If I am in a minority of one, they send for a doctor or lock me up; and I am so far able to transcend the to me convincing testimony of my senses or my reason as to recognize that if I am alone probably something is wrong with my works."

WYALIN

Wyeth's Biliary Stimulant

Pancreas, Common Duct, Portal Vein and Duodenum are shown through the Phantom (transporent) Stomach

Wyalin is especially useful in biliary disturbances and is also of value in intestinal stasis and other bowel disturbances where a digestant and gentle laxative is required.

BILE SALTS—Natural cholagogue. The only true cholagogue which stimulates the liver to secrete bile. The bile thus formed is Nature's Laxative—very mild and harmless in its action. Assists in the absorption of fats and regulates the intestinal flora.

EXTRACT NUX VOMICA—Stimulates gastric secretion and bowel action.

ENZYMES (LIPASE, TRYPSIN, AMYLASE)—Digest fats, earbohydrates and proteins in the bowel.

EXTRACT CASCARA SAGRADA—Increases tone and peristalsis of upper and lower intestines.

Wyalin contains no phenolphthalein.

Supplied in bottles of 50 and 500 tablets.

May we send you a sample of Wyalin for a clinical trial test?

Control the integrity of your prescription's by specifying Wyeth's pharmaceuticals,

JOHN WYETH & BROTHER, Inc. PHILADELPHIA, PA. AND WALKERVILLE, ONTARIO

With resources beyond any private institution, the State of New York has ereated at Saratoga Springs bath facilities (private and semi-private) which commend themselves and the therapeutic utilization of these natural mineral waters to the profession. Beyond simple tonic baths for the physically or nervously debilitated, the State Baths are equipped and staffed to administer such special treatments as

Saratoga Cardiac Therapy
Neuro-Vascular Training
Eliminating Treatment
Massage—Irrigation
Packs and Fomentation
Mechano-Therapy
Light-Therapy

In the quiet, bracing atmosphere of Saratoga Springs there are available hotel and housing accommodations with special services in dictary control, and all conveniently located near the bathing establishments.

Members of the profession are cordially invited to be the guests of the State at the baths while in Saratoga Springs. For complete information about the Saratoga State Baths and bottled Mineral Waters, address: Medical Director, Saratoga Springs Commission, Saratoga Springs, New York.

An editorial in the New England Journal of April 20 comments on the possibility that an undue number of American students now in European medical schools may seek licenses to practice in Massachusetts, and says:

"If rejected in other states, it would be reasonable to expect that such disappointed doctors will regard this Commonwealth as a possible resource. Under such circumstances Massachusetts will be the choice, for most graduates wish, and some will need, to get into practice as soon a possible.

"Massachusetts will not be in a position to exercise discriminatory power unless her legislators have a change of heart. Her policy is to open her doors to many who cannot secure recognition in any other state,

"There is no doubt but that the future will see changes for the better but this is not likely until the general public shall have come to realize the great importance of a body of practitioners comparatively well equipped to deal with the health of the people.

"Our leaders are striving for this awakening but it will be deferred unless the nearly five thousand better equipped doctors unite in an educational campaign."

SOUTH CAROLINA JOURNAL FOR THE GENERAL PRACTITIONER

The Journal of the South Carolina Medical Association for April has the following editorial

"For the first time, so far as we know, a State Journal issue is being dedicated to the general practitioner. For the first time also, this special number of the Journal brings into action the full battery so to speak of its Associate Editors with the one aim that every editorial by them shall present to the general practitioners of South Carolina something worthwhile that they may utilize in their daily rounds of practice. Our able staff of Associate Editors deserve the highest commendation from the members of the South Carolina Medical Association. Special editorials by past Presidents of the South Carolina Medical Association appear also in this issue of the Jour-We are supported in our belief that a better day for the general practitioner is now on the way by many authorities."

The Journal prints three editorials on the General Practitioner, one saying:

"A woman of notable intellectual capacity and cultivation recently told the writer that the method of a certain nationally known institution having pathological details worked out by subordinates, and their findings (as if they could be relied upon) formulated and accepted by their chiefs as

BROOKLYN NEWARK SPRINGFIELD WILKES-BARRE DETROIT BOSTON (Continued from page 966—adv. x)

the basis of diagnosis and therapy, was intellectually a joke and morally a tragedy. Professionally speaking such methods can only mean slow, but certain suicide. This is the raison d'être of Christian Science, osteopathy, chiropractic, et id omne genus.

"The sick man or woman demands personal attention and if the regular and legitimate profession does not and will not render it, then he or she is going to turn to somebody who does. This is one reason, and a potent one, why the modern trend to so-called 'clinics' is doomed to fail. And this is why the recent report of The Committee on the Costs of Medical Care does and will lack the sympathy and endorsement of the large majority of high-toned and intelligent physicians of this country.

"There should be scant sympathy for the man who practices any branch of medicine on a basis of laboratory diagnosis. When the experienced clinical observer and the laboratory technician lock horns, it is the part of wisdom to trust the former every time, and this is the psychology of the situation that is invariably sensed by the alert patient."

DISPENSARY PATIENTS IN PENNSYLVANIA

The Medical Society of Allegheny County, Pennsylvania, has passed a resolution on dispensary treatments according to the June issue of the Pennsylvania Medical Journal. The plan recommended by the county society is as follows:

"1. That all social agencies and dispensaries will refer patients who at one time or another have been under the care of a private physician back to that physician. Persons who say they have no family physician but who might be self-sustaining are to be referred to a neighborhood physician.

"2. That the physician to whom such patients are referred will proceed in one of the

following ways:

"(a) To treat the patient for such fee as he and the patient agree is fair.

"(b) To treat the patient on a deferred payment basis.

(c) To treat the patient free.

"(d) To refer the patient to a dispensary in writing.

"3. In order to eliminate duplication of work by dispensaries, patients who have been under observation at a given dispensary shall continue to report to that dispensary unless adequate cause exists for a change.

"4. That the plan is not to apply to emergency cases nor to cases under treatment by dispensaries at the time of its inauguration."

CARE OF RURAL INDIGENTS IN VIRGINIA

The May issue of the Virginia Medical Month In contains the following account of the care of the indigents in a rural county

"The amount of charity work demanded of the average physician in the country is beyond all reason, yet of course those absolutely unable to pay should not be allowed to suffer. The Board of Supervisors of some countes have been paying bills submitted to them for treatment of indigent cases, but no satisfactory system in this has been devised whereby all can be helped and the physicians receive anything like adequate compensation. The physicians should be paid a reasonable amount for caring for indigents, it is just as much the duty of the county to do this as it is to pay for sheep killed by dogs, or provide julks for the punishment of crime.

'Warren county is trying out a plan which we believe is fairly sitisfactory to all concerned and in a modified form, probably might be carried out successfully in any county

In March, 1932, the Warren County Board of Supervisors looked about for a way to economize and yet do justice to the physicians and the indigent sick. The following arrangement was agreed upon. Lach of the three physicians of the county is to be paid a stated

sum for the services rendered county dependents during 1932 1933, the physicians each serving a month at a time, making a total of four months per annum, per physician. The person needing medical aid must get an order to the effect from the county overseer of the poor

"The Board realized that medical treatment is often ineffectual because the doctor's orders are not carried out, so the public health nurse was instructed to visit the families receiving treatment and give them such instruction in hygienic matters as seemed most needed

"The County Medical Service to the Indigent and the County Public Health Association drew up the following list of requisites for free medical attention

'1 Families of patients must follow the instructions in hygiene given by the physician and the nurse in caring for the sick members

"2 Patients with communicable diseases must follow the directions given by the physician and the mirse, and obey the riles of quarantine and isolation.

"3 (a) Prenatal cases must report to the Health Center in their districts at least five months before the time of expected delivery

(b) Expectant mothers must attend the conference periods held in these places for their (c) Each mother must visit a instruction. physician for examination at least once before delivery, and take the baby with her for examination when it is six weeks old. (d) Each expectant mother must follow the nurse's instructions in preparing for delivery.

"Warren County has four physicians this year in active practice, and if the present plan continues in operation, it would seem that satisfactory results should be forthcoming."

THE INDIGENT IN CALIFORNIA

The June issue of California and Western Medicine contains an article on the plan of Fresno County for the care of the indigent. The county is situated in the south central part of the State and has a population of about 60,000, of whom over 50,000 are in the City of Fresno. The care centers around the County General Hospital. Its patients are divided into five groups:

1. Indigent,

2. Part Pay,

3. Pay,

4. Non-eligible,

5. Non-residents.

These groups are discussed as follows:

"The Part Pay Group comprises patients who can afford to pay very little for medical care but who desire to retain their self-respect by meeting The Social Service Departtheir obligations. ment, after a social service interview, determines what the patient can justly afford to pay. The medical society will furnish a list of physicians who have agreed to care for these patients at prices established by the Social Service Department. The charge may be as low as twenty-five cents."

The county has a scheme for hospital insur-

ance which is described as follows: "The Pay Group comprises patients who can afford to pay the physician for his medical attention at the regular or at somewhat below the isual rate. This group, however, cannot also afford hospitalization at the present time. To these patients, the physicians and other agencies should attempt to sell the Hospital Insurance. This insurance plan is similar to other hospital insurance plans. It provides patients with hospitalization for \$12.00 per year, payable on a monthly installment basis. This hospital insurance is to be under the supervision of the Fresno County Medical Society. If hospitalization is necessary, before elapsed period, as specified in the hospital plan, physician may refer the cases to Social Service Department for disposition. A Social Service worker will contact such patient

(Continued on page 971-adv. xv)

(Continued from page 970-adv. xw)

and determine whether or not he can meet hospital rates on the installment plan. Such patient will then be sent to a private hospital if such is willing to accept him on an installment plan; otherwise he will be referred to the General Hospital for care. Non-eligibles are referred to private physicians and receive no treatment in the General Hospital unless entered as an accident or emergency case. Non-residents are not eligible in the General Hospital unless the case is one of extreme emergency. Otherwise the patient will immediately be referred to the county where the residence has been established."

An advisory committee is described as follows:

"There was also created an Advisory Admission Committee to handle disputes and doubtful cases. The commission consists of six members, which are as follows: (a) Member of Board of Supervisors, chairman, Hospital Committee; (b) Director of Welfare Department; (c) Director of General Hospital; (d), (e) and (f) Members of Fresno County Medical Society. This commission will elect a chairman to landle minor disputes and receive reports on all cases handled through the Social Service Department. The decision of the commission shall be final as to the eligibility of a patient for county care."

The Fresno County Medical Society adopted

resolutions to put these plans into effect.

ANNUAL MEETING IN WYOMING

The Wyoming section of Colorado Medicine for July contains the following announcement:

"It is with a deep sense of disappointment that the officers of the Wyoming State Medical Society announce that there will be no meeting this year.

"Many hours have been given in arranging the program for the Yellowstone Park meeting, but the decision of the other state societies to postpone the Yellowstone Park meeting came too late to arrange a state meeting to take its place. Perhaps it is for the best. Who knows? But one thing is certain—that the abandonment was not the personal wish of our President, Dr. F. L. Beck.

"In the meantime allow a suggestion to sink m—so far as you can, plan to attend either the Colorado, Utah, Idaho or Montana meetings this year. See how they conduct their affairs and bring back the good points to your own

A "Junior" Model for the Petite Mother

I MPENDING motherhood requires a support properly proportioned to the particular figure type—suited to stature and other individual body requirements—as all Camp maternity garments are. For the slight young woman, the model illustrated (No. 3231), known as a "Junior," is specially designed. It is shown on an actual six-month pregnancy ease. Of course, it has the exclusive Camp Patented Adjustment feature which adapts it to the figure and to maternal development and regulates pressures. It provides needed sacro-iliae support and relieves undue pressures on organs. Incidentally, it has a smooth habit back, with lacings and adjustment on side; also elastic side sections over hips.

Sold by Surgical, Drug and Department Stores and Corset Shops. Write for Physician's Mannal.

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To void delay in publishing, remit with order. Price for 40 words or less, 1 insertion, 1.50; three cents each for additional words.

Retired Physician offers his beautiful mod-rn home for sale. Well located to command ractice. Valuation \$35,000. Price \$25,000. lasy terms. Fruits and flowers. One block rom Ocean. P. O. Box 73, Allenhurst, N. J.

House for Sale, 2402 Ave. "R," Flatbush, trooklyn, N. Y. 10 rooms and double garage, we baths. Beautiful grounds. Ideal corner cation for a Physician. Will sell very reasonbly. Phone ESplinade 5-3365. M. Lehman.

GENERAL PRACTITIONER WANTED
On a recreation farm, near Liberty. N. Y.,
or German workmen. Some with TB. Maried preferred. Salary per year \$1,200.00 and
naintenance. Address Box 22, care N. Y.
tate Journal of Medicine.

Opportunity for physician to purchase the esidence and office of the late Dr. Jesse rounse in Altamont, Albany Co., N. Y. A illage of 1200, adjacent summer colony, rural ollowing. Nine rooms, steam heat, two car arage, flowers, fruit. C. E. Van Auken, 437 state St., Schenectady, N. Y.

PABLUM-MEAD'S PRE-COOKED CEREAL

Mead Johnson & Co. are now marceting Mead's Cereal in dried precooked form, ready to serve, under the name of Pablum. This product combines all of the outstanding mineral and vitamin advantages of Mead's Cereal with great ease of preparation.

All the mother has to do to prepare Pablum is to measure the prescribed amount directly into the baby's cereal bowl and add previously boiled milk, water, or milk-and-water, stirring with a fork. It may be served hot

or cold and for older children and adults cream, salt and sugar may be added as desired.

Mothers will cooperate with physicians better in the feeding of their babies because Pablum is so easy to prepare. Please send for samples to Mead Johnson & Co., Evansville, Ind.

WHAT IS MALTCAO?

Maltcao is a scientifically prepared health food consisting of pure sugar, malt, cocoa, partially defatted milk, and liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in grains and vegetables.

"MALTCAO" ANALYSIS:

Moisture	3.03%
Cocoa Butter	4.42%
Butter Fat	.56%
Milk Solids not Fat	10.09%
Crude Fiber	.89%
Cane Sugar	45.07%
Maltose	14.72%
Total Protein	9.87%
Dextrin and Other Carbo-	
hydrates	7.36%
Mineral Ash	3.99%

100.00%

The ash contains:

Sodium Chloride	0.84%
Iron	0.09%
Calcium Oxide	0.52%
Phosphates as P ₂ O ₅	1.41%

FROM A LILLY BULLETIN

"The benefits derived from the use of local medicinal agents commonly prescribed in nasal therapy would appear to depend to a considerable extent upon the manner in which they are applied. Some physicians recommend the use of sprays, while others favor drops. Linn has called atten-tion to the value of double spraying; the first shrinks the exterior turbinate, allowing the second spraying to reach more readily the important middle turbinate area. According to Jackson and Coates, gravity will carry further into the recesses of the nose and sinuses than a spray or applicator. In applying drops by the gravity, or postural, method, the patient lies on a couch or table with the head well down over the end. The drops, usually about ten, are instilled into each nostril. The head is then rolled from side to side. After two or three minutes a normal recumbent position is resumed and should be maintained for from three to five minutes. During this procedure the patient is instructed to breathe through the mouth and not to 'sniff.' Gentle tapping over the forehead may facilitate the spread and penetration of the drops."—Adv..

KALAK WATER

Many diseases are complicated by an "acidosis." An important part in their treatment consists in replacing those elements needed to maintain the alkali reserve.

.41% In clinical practice a rational and agreeable method of alkalinization is afforded in Kalak Water.—Adv.

THE WYATT-HICKS STREPTOCOCCUS ANTIGEN

For Intravenous Use In The Treatment Of CHRONIC INFECTIOUS ARTHRITIS

While protective immunity and desensitization in a large percentage of cases follow the administration of this antigen, it should always be regarded as merely one adjunct to a well-balanced, composite program of therapy.

THE CARE OF THE CANCER PATIENT

By DOUGLAS QUICK, M.B. (Tor.), NEW YORK, N. Y.

The Bulkley Lecture before the New York Academy of Medicine, March 31, 1933.

THERE are many and varied problems confronting the family physician charged with the family health and management relative to the caucer problem. His responsibilities extend all the way from cancer prevention and early diagnosis to decisions on treatment measures. All too frequently it embraces the very trying terminal care of the case in which those measures have failed. Many attendant medical problems arise. Not only the patient but the entire family requires guidance and management.

The physician in general practice sees, on the average, three to four cases of malignant neoplastic disease per year. It is too much to expect that he be at once familiar with all the varied phases of the vast group of allied diseases coming under the general heading of cancer.

One of the trying difficulties centers round the term "cancer" itself. At mention of cancer all too many physicians assume an attitude of resignation. Such being the case, what are we to expect of the patient and the family. Their reaction is one of terror. The term "cancer" covers the entire field of malignant neoplasms. It is probably necessary—indicating a group of diseases allied by virtue of a common characteristic.

That group of diseases is the largest in the entire field of medicine. The common characteristic—the development of malignant new growth—varies tremendously between groups and even within those groups. Such distinction, however, is not usually made within our minds when the word "cancer" is mentioned. Therein lies the damage to the morale of the average individual. The classic popular picture of cancer—pain, distressing ulcers, inanition, the well-blanketed armchair and opiates—arises as a mental spectre. A calm, well-blanced appraisal of the actual condition is not made. The fact that some groups of malignant diseases are curable in percentages ranging from 70% to 90% or 95% is lost sight

of. The gradual improvements in clinical therapeutic measures of the past decade are forgotten. Even the improved palliative measures for the ultimately incurable are overlooked. The use of the actual term "caucer" carries with it today the same distressing mental reaction that it has for generations. The only conceivable value in its popular usage may be as an urge to careful periodic health examinations by the public and thereby the recognition of pre-cancerous and early malignant manifestations.

In established cancer no useful purpose is served by unrestricted reference to it as such. The fancied cooperation gained through a knowledge of the seriousness of the disease, by the patient, is a cooperation of fear. A few strong-minded individuals may be able to profit by participation in a knowledge of actual conditions. It is questionable, however, if even this is justifiable unless to permit of caring for responsibilities to dependents.

PRE-CANCEROUS MANIFESTATIONS

In the light of our present knowledge of neoplastic diseases it is not enough to accept responsibility only for the care of fully developed cancer. Many of these may be and can be avoided. It is true that we do not know the cause, or causes, of cancer-and more than probable that this generation will be denied the secret, if such there be. We are familiar, however, with many "contributory" causes: We recognize certain "precancerous" The removal or care of these is usually simple; and while not as spectacular as the cure of an established malignant growth, is, in many respects, more important because of the relative numbers involved. The prevention of cancer by removal of a contributory exciting cause or removal of a tissue bed, the seat of chronic inflammatory changes suitable for the devolopment of new growth, is as much to be commended as the control of the lesion once it is fully developed. It is by

such measures that true cancer control will become effective. It is only through a very substantial grasp of the entire problem by the profession as a whole that such warning signs and preventive measures will be recognized and acted upon.

Chronic irritation of tissues is recognized as a definite contributory factor in the development of malignant disease. In its simplest form it may be noted on the skin surface, and in many instances either relieved entirely or so reduced in severity that growth stimulus will be lacking. The various senile changes in the skin are well recognized, and are prone to malignant degeneration. In those exposed to the elements, such changes may be more marked at an earlier period in life. Some individuals have peculiarly sensitive skins which are prone to become irritated over a period and remain so. This is particularly true with respect to sun and wind burns. Occupational irritations of the skin may assume a great variety of forms, and certain of these occupational dermatoses, some of which ultimately become malignant, appear to be more specific than others, notably, the mule-spinner's or chimney-sweep's cancer. Prolonged irritations may ultimately provide a suitable soil for the development of new growth. Recognition of the earlier changes in these conditions will naturally forestall the ultimate and posmore serious side. Certain notably arsenic, which after prolonged administration produce a chronic dermatitis, in certain instances, are apt to be followed by the development of skin growths. The same is true of direct contact with arsenic in industrial work.

I doubt if in any of these conditions there is anything specific in the sequence of events ending ultimately in the appearance of the neoplastic process; usually rodent ulcer. seems most probable that the changes in the accompanying and resulting in chronic dermatitis merely furnish a suitable set of conditions for the subsequent develop-ment of the neoplasm. The same is true of growths developing on the basis of old x-ray and radium burns. The statement is often made that these agents produce skin cancer, after a time. Such is not the case. There is nothing specific in the reaction to radiation in the skin, so far demonstrated, to lend the least support to this idea. The atrophic changes furnish a suitable set of conditions for the development of new growth. If the original skin damage from radiation be relatively superficial and non-ulcerative in character, basal cell carcinoma, similar to that found in connection with other superficial irritants, is to be anticipated in a certain percentage of cases.

On the other hand, if the destructive process is deeper, influencing more profoundly the entire thickness of the skin, squamous cell carcinoma is usually the type of growth, if a malignant process supervenes. The great number of small congenital abnormalities of the skin, warts and moles, are liable to degenerative changes later in life or in certain locations to chronic irritation. Their removal should almose invariably be advised.

Contributory Factors in the Mouth-Of all known contributory factors, those incident to poor oral hygiene are most definite and most These may be briefly enumerpronounced. ated as rough and irregular teeth presenting sharp corners and cavities in which food debris may be lodged; poorly placed fillings and neglected dentures; particularly fixed dentures which do not lend themselves well to cleansing. Ill-fitting dental plates should be particularly emphasized, since after a time they not only present rough surfaces about the teeth to irritate the membrane of the tongue and cheek, but they are very apt to damage the alveolar borders without being noticed for some time. Over a period of years the contour of the bones of the face changes, but the dentures remain the same shape. The wearing, therefore, of the same plates without readjustment for many years is a very frequent source of chronic irritation which ultimately develops into adult growth.

Dentists, as a group, are usually keen to recognize many of the early changes which may ultimately have a bearing on the development of new growths within the mouth, but they are often singularly negligent of the various factors which may be producing these early changes. Too many of them confine their activities to the direct repair of the teeth without taking sufficient cognizance of their patient's oral hygiene in general.

Excessive smoking undoubtedly plays a part as a contributory factor. The relative sensitivity of the mucous membrane varies to a considerable degree in different individuals. It is, therefore, smoking in excess of one's individual tolerance which does the damage. Within moderate limits, it apparently does no appreciable harm.

In connection with the tongue in particular, the persistence of heavy coating, which may be due either to accumulated debris or actual fungus growth, is capable of having far-reaching effects, over a period of time. As a bacterial culture-medium it excels, and as such contributes toward the infection and reinfection of the lymphoid tissue about the pharyngeal ring.

Syphilitic manifestations within the mouth contribute, to a certain degree, toward the

ultimate development of cancer-not because of any specific relationship between the two diseases but by furnishing a suitable tissue bed in which a new growth is prone to develop, just as in the case of the x-ray dermatitis of the skin. This is true in connection with either luctic leukoplakia or luctic glossitis, or both, since the latter is almost invariably accompanied by the former. True luctic leukoplakia is not uncommon, yet leukoplakia of luetic origin within the mouth accounts for only a small percentage of all intra-oral leukoplakias. It is fallacy to assume that all leukoplakia of the intra-oral mucosa is at once suggestive of luctic infection. Poor oral liygiene in general, points or irritation on neglected teeth or dentures, and excessive smoking, account for the major portion of True luetic leukoplakia is these changes. usually more marked, involves the mueosa more deeply, and is probably more prone to malignant change than leukoplakia incident to other causes.

The influence of oral sepsis as a contributory factor in the subsequent development of cancer is probably not limited to the oral cavity. Its influence on the upper digestive tract particularly is probably far underestimated. All of these many simple factors attendant upon the proper daily and routine care of the mouth come constantly under the eye of the family physician and dentist. Unfortunately, in the routine course of events, they are too frequently overlooked or neglected. There is no doubt that a tremendous amount of intra-oral cancer could be avoided by proper attention to these simple details. is the duty of the family physician and dentist to take seriously, and insist upon a proper recognition on the part of their patients, of this phase of preventive medicinc. It is not too much to say that with proper attention and cooperation intra-oral cancer could be largely avoided.

Breast—Precancerous lesions and factors contributing toward subsequent development of new growths in the breast are less clearly defined than those just referred to. Certain outstanding features, however, are worthy of mention. It is only reasonable to look upon the frequent irritation of the areola and nipple as contributing something by way of changes which may ultimately terminate in Paget's disease, even though the actual development of growth may be deep to the areola. While the bleeding nipple has long been mentioned in textbooks as one of the cardinal signs of breast cancer, it is probably overdone on this score. On the other hand, it does call attention very frequently to the duct papilloma which, while in itself benign, does not always

remain of the same structure—another example of the tissue in which change in structure is apt to take place as time goes on.

The subject of chronic mastitis is debatable and cannot here be discussed at length, since we are concerned, for the moment, only with those changes which may ultimately contribute in some measure to the development of a malignant process. Since it produces mild yet persistent symptoms, and since it produces gross histological changes throughout the breast, it at least deserves the treatment which would be accorded a low-grade chronic inflammatory process elsewhere.

While the relationship between a single direct injury and the subsequent development of cancer is extremely debatable and undoubtedly rare, it is true in connecton with the breast that an indirect hazard, at least, may be associated with such injuries as the scarring from the opening of abscesses and the careless introduction of hypodermoclysis needles. Definite instances of a relationship between the results of these injuries and the subsequent development of cancer occur from time to time. There is ample evidence, both experimental and clinical, at present to regard faulty drainage of breast secretion as another source of chronic inflammatory change which may contribute, in some degree at least, a suitable tissue bed for the ultimate development of growth. All forms of chronic breast inflammation, no matter what the source, should be regarded as dangerous to some extent at least and should be treated, in so far as practicable, with the object of reducing or relieving this inflammation on account of its ultimate potential possibilities. If chronic inflammatory changes on a simple skin surface are capable of providing a suitable tissue bed in which a new growth may develop, it is only reasonable to assume that similar changes in a complex structure, such as the mammary gland, may be all the more dangerous.

Uterus-Unusual uterine bleeding, and particularly any bleeding beyond the menopause, ought to be too well recognized, as to its possible significance, to call for comment, yet it is surprising how frequently it is ignored for a few weeks or even for a few months until malignant disease is well established, often beyond the possibility of cure. The conditions which so very frequently preeede the cardinal evidence of new growth in this organ are, to a very large degree, overlooked entirely. Old lacerations of the cervix uteri, with the attendant tissue changes about these scars and with inflammatory exudates from them irritating surrounding tissues, are usually ignored. This is merely another example of a condition, which if corrected would eliminate a considerable number of one of the commonest types of malignant disease.

Another source of chronic irritation and chronic inflammation which should be watched for and given proper treatment when recognized, is the faulty drainage of secretion from the fundus uteri. Instances of the development of adenocarcinoma of the corpus uteri, associated with and incident upon this condition, are accumulating. Observations on different races and classes of people whose habits differ point clearly to the fact that personal cleanliness in the habits of every-day life have considerable bearing on the relative percentages of carcinoma of the cervix in the different groups. The inference is self-evident.

Gastro-intestinal Tract-In connection with the upper gastro-intestinal tract, that is, from the esophagus to the small bowel, we have little specific information as to definite contributory causes in the development of cancer which may be watched for on the part of the physician, or avoided. The varying degrees of sensitivity of the mucous membrane in different individuals make the matter of irritation, from different types of food, a relative matter. It is doubtful if any practical, worth-while conclusions can be drawn. suggestion that oral sepsis may be of greater importance in these organs than the character and temperature of the food taken is worthy of consideration and further investigation. In the colon and lower bowel certain anatomical abnormalities are of practical significance.

Polypi and diverticula are recognized as potential points of irritation and inflammation. Malignant disease may subsequently develop in either. Unfortunately, both are apt to be multiple, so that it is usually impractical to remove all of the potential danger points. On the other hand, recognition of the condition plus careful routine watching will at once draw attention to any unusual change and thereby permit of proper treatment of the suspicious area before unrecognized growth extends out of bounds.

Rectal bleeding should always be taken seriously. Whatever the source of bleeding may be, it should be corrected immediately. A diagnosis of hemorrhoids should never be accepted as such without eliminating the possibility of early new growth, and a diagnosis of hemorrhoids should never, under any circumstances, be made across the corner of an office desk.

In following the gastro-intestinal tract from the standpoint of cancer prevention, the clinician should be advised against placing too much reliance on negative x-ray findings in the lower bowel. The relative value of this diagnostic method is much greater in the upper tract than in the lower.

Diagnosis—The factor of vital importance in the care of fully developed cancer lies in its early recognition. This fact is stressed by every cancer agency but its repetition can scarcely be overdone. The efforts put forth to make this a matter of household knowledge are not being wasted. The apparent increase in cancer is, to some degree at least, an increase in the frequency of its recognition—in other words, more accurate diagnosis. Unfortunately, too many of these diagnoses are still made entirely too late.

The facilities for diagnosis are, for the most part, reasonably adequate. The unfortunate point is that the advantages of these facilities are too often neglected until the favorable time for treatment has passed. It is on this point in diagnosis that stress should be laid most forcibly.

If the clinician would regard cancer as a large group of closely allied diseases rather than as a single entity, a considerable advance would at once be made from the standpoint of diagnosis. The notion that anemia, cachexia, pain and foul discharges must be present before cancer is to be suspected is the greatest fallacy. At this stage a diagnosis of cancer is usually of value only to the department of vital statistics. Routine health examinations, if carefully and seriously done, will contribute tremendously toward the early diagnosis of many malignant growths. Unfortunately, most of these neoplastic processes are insidious in their onset and many may be practically symptomless. More careful and complete examinations of the patient and less consultations, beyond a reasonable point, will advance and simplify the general problem of cancer diagnosis.

With the present development of x-ray and laboratory aids to diagnosis, there is little excuse for overlooking most early new growths in a routine examination. The intra-abdominal group comes nearest to being an exception.

While a great deal has been said for and against the advisability of the taking of tissue from a questionable area for diagnosis, the practical fact remains that whenever in doubt, biopsy, where reasonably practical, will do far less harm than the leaving of a malignant growth to develop to the point where it establishes its own diagnosis. The resort to biopsy should, of course, always be determined upon reasonably. The piece of tissue removed for section need not be large. Trauma of surrounding tissues should be avoided with the utmost care. The opening into normal tissues, either for access to the

tumor-bearing area or by extending through the growth into normal tissues of the tumor bed, should be avoided wherever possible. If it is necessary, in obtaining tissue for histological examination, to gain access by surgical exposure, the wound should be closed very carefully by approximating the various layers of tissues incised, separately, in order that subsequent fungation of tumor tissue may be avoided.

Within certain limits, external irradiaton as a therapeutic test may be of value in aiding confirmation of a tentative clinical diagnosis where the tumor suspected is particularly radiosensitive. On the other hand, one should not be deluded by placing too much dependence upon this type of verification. It is of value within very narrow limits only, and only then in the hands of an experienced can-

cer clinician.

In the differential diagnosis of many tumors, particularly those presenting an ulcerating surface, tertiary syphilis must be considered. A positive Wassermann, however, must not be taken as conclusive that the lesion in question is undoubtedly luctic. Biopsy should also be resorted to if the clinical picture is at all questionable from a luetic standpoint. Antiluetic treatment should only be persisted in for a brief period in the absence of clinical improvement before reconsideration is given the diagnosis. A positive Wassermann or Kalın reaction, with or without a luetic history, does not preclude the possibility of other Too frequently the possibility of cancer is ignored because of the positive blood reaction.

TREATMENT

The treatment of any malignant growth might well be considered under one of the following headings: Curative, palliative or

psychological.

If, after giving due consideration to the type of growth, and its degree of advancement, there seems to be a reasonable opportunity for its complete eradication, then the measures decided upon for the treatment of that particular case ought to be exerted to the limit, whatever those measures may be. On the other hand, if palliation only is possible, every consideration ought to be given the patient's comfort from day to day and no therapeutic measures resorted to which will unduly upset the patient when nothing definite may be anticipated in return.

Considering the entire field of malignant diseases, from the simple rodent ulcer, probably 95 per cent of which are curable, to the osteogenic sarcoma and the active melanoma, in which the expectancy of cure is very slight, the average of actual curability for the entire

group of malignant neoplastic diseases is probably not more than 30 per cent. This leaves a very large group in which palliative treatment, sooner or later, comes to be the only resort. The degree of actual physical palliation, of course, varies with different types of the disease and is dependent upon many varied factors. In these cases, the manner in which they are handled from a psychological standpoint is most important and those who assume the responsibility of caring for these unfortunate people would do well to study most seriously the various psychological problems present in the individual case.

Specific Therapeutic Measures-As far as the active and direct treatment of new growth is concerned, it is almost entirely surgical, operative or otherwise. The only agents at our disposal at the present time for direct treatment are surgery, x-rays and radium. It is in the proper selection and application of these measures, or in their various combinations, that the chief advances have been made in the treatment of cancer during the last decade. Surgical technic has reached a high state of perfection. The technical procedures incident to the application of x-rays and radium are improving, yet the use of these physical agents is of such recent date that much more can be reasonably expected in the future than has been accomplished in the past. The value of these agents should not be appraised today on impressions or experiences gained from the manner in which they were employed a few years ago. It is in the development of proper usage of these physical agents, combined wherever advantageous with the benefits of conservative surgery, that most may be expected in the future treatment of cancer.

The physical agents should be regarded as just so much valuable additional equipment to add to the strictly surgical equipment which the surgical experiences of the past have brought to such a high state of perfection. It is no longer necessary to attempt an operative procedure on the inoperable case, simply because some effort at relief must be made. Furthermore, in the otherwise technically operable case, radiation in some of its various forms is likely to be of assistance, either by way of rendering the surgical procedure safer or by limiting the necessity for some of the spectacular, yet extensive, operative proced-ures which have been attempted as heroic efforts toward controlling certain of the more malignant or more advanced types of disease. In other words, through the assistance of radiation, the character of presentday cancer surgery has been very decidedly altered. Some of the most extensive operative surgical procedures have been entirely replaced or modified by the physical agents. Of this, carcinoma of the cervix furnishes probably the most outstanding example. the other hand, carcinoma of the fundus uteri remains a problem for operative surgery, with The disor without associated irradiation. ease is of a different type both histologically and anatomically, and, as such, lends itself much better, in the present state of our knowledge and advancement in therapy, to surgical removal than to treatment by irradiation alone, in the uncomplicated case. However, if the disease be advanced to such extent that complete surgical removal is not assured or, if for any reason the general physical condition of the patient does not warrant an extensive operative procedure, the benefits to be derived from radiation are such that the surgical steps may well be replaced by the other methods.

In some cases, preliminary irradiation, followed by surgical removal of the growth, affords the patient a better chance for ultimate cure than would be the case if the surgical procedure alone were carried out. This is well exemplified in cancer of the breast. not infrequently happens that an operative surgical procedure is undertaken with the expectation of being able to do a complete removal of the tumor, only to find as the operation proceeds that this is impossible. Through the advantages to be gained by implantation of radium emanation, an otherwise unsuccessful operation may be turned into a successful procedure by resorting to implantation of radon to care for that portion of the growth which cannot be safely or successfully ex-The implantation of radium or radon, as an extra safeguard, as the final step in an otherwise clean surgical dissection, is in certain instances dependent upon a general routine procedure, as in the treatment of operable metastatic epidermoid carcinoma in the neck and inguinal regions.

Certain of the surgically inoperable tumors may, in addition to heavy external irradiation, be handled best by following this external treatment by surgical exposure of the tumor for the purpose of accurate radium implantation throughout the tumor-bearing area. this connection, many new surgical procedures for the purpose of exposure and approach to tumor-bearing areas must be devised to meet the requirements of the individual case. It becomes apparent, therefore, that while some of the older surgical measures have been replaced by radiation, other surgical procedures have had to be devised to meet the ever changing conditions, as our knowledge of the application and value of the physical agents progresses. In other words, the

character of cancer surgery today has changed to such an extent that it may well be considered one of the special fields of general surgery.

There should be no confusion as to the relative place of x-rays and radium in the treatment of cancer. X-radiation may be employed only for external application and for the most part over large areas. From an economic standpoint there are several advantages to be considered and there is no limitation on the supply. Additional x-ray equipment is always available. Radium, on the other hand, lends itself best to application within body cavities, over localized surface areas, and, most important of all, for direct implantation within the tissues. There is some difference in the quality of radiation between the gamma rays of radium and the hardest x-rays obtainable with our present-day equipment. However, this need not be given particular consideration here. It is true that if adequate quantities of the radiation from both sources are available for comparison, the gamma rays of radium are more effective and more efficient than the best that can be produced through an x-ray tube at this time. The supply of radium, however, is limited and the advantages which it affords must, of necessity, be limited to a relatively few patients. X-radiation must be depended upon to furnish the major portion of the external radiation in routine work throughout the country. A good dose of x-radiation is always better than a poor dose of radium radiation. The treatment of larger tumors, particularly at depth, or the treatment of large surface areas by external applications of radium, should never be attempted unless a very large radium supply is available.

The advances made in x-ray therapy and equipment for x-irradiation during the past year or two warrant a substantial degree of optimism in that direction. The possibilities and probabilities for the future development of x-ray therapy strongly suggest that the surface has only been scratched in the ultimate development of this type of radiation.

Quite apart from the relative position which radiation may hold in the treatment of the various types and groups of malignant disease, it is a fact that the use of these physical agents has changed very considerably the outlook on cancer in general. Its use has stimulated a tremendous amount of histological study, without which reasonable and intelligent application of the physical agents would be impossible. Through this intensive study, new conceptions of the general problems of cancer have been gained, and several new types of the disease have been recognized as definite clinical entities.

The work in histological grading of tumors bears a relationship to the relative radiosensitivity of tumors to irradiation. The two are not in parallel. However, they serve, collectively, as a very valuable guide in the selection of treatment method or combination of methods. The fully differentiated tumors are relatively slower in growth, less liable to widespread secondary dissemination, more resistant to a given quantity of radiation. It is in these that surgery offers most. Anaplastic growths tend to metastasize early and at distance, hence the likelihood of control by extirpation is slight. Fortunately, they are much more radiosensitive and consequently are more dependent on irradiation as the treatment of choice.

It would be impossible, here, to go into a discussion of the effects of radiation on tumor tissues. It might be well, however, to point out that the beneficial effect of radiation from a therapeutic standpoint is not limited to its effect on the tumor tissue alone. It is quite possible that the effect on the surrounding normal tissues or, as it has been very aptly termed, the tumor bed, is quite as important as the direct effect upon the neoplasm itself. This has a very considerable bearing not only on the technical methods of irradiation, but also upon the manner in which irradiation is combined with operative surgical procedures. The problems incident to the proper combination of these various methods and their application in the individual case, call not only for special facilities, but for special training as well. Special facilities with special training, and the cancer service in the general hospital is the least that can be considered consistent with the present needs of dealing adequately with the cancer problem. This is not meant to suggest that the cancer patient be taken away from the family physician, but rather that the special equipment and special training necessary to assist the latter in meeting the peculiar problems incident to the individual case be made accessible to the man who, after all, must carry a very considerable portion of the burden in connection with the treatment of any case of malignant disease.

Constitutional Measures—The general medical care of a cancer patient is too often overlooked or, for the moment, forgotten under the stress of the immediate problem. Malignant disease may and does exist in conjunction with many other grave medical conditions. This is particularly true since the so-called cancer age is also the period of life during which the system begins to show the effects of wear and tear in general. Cardiorenal disease, diabetes, and tuberculosis must be cared for just as carefully or more so in

the presence of cancer as at any other time. No strenuous therapeutic procedure, operative or otherwise, for cancer should be undertaken without a eareful, unbiased appraisal of the patient's general physical condition quite apart from the immediate problems incident to the malignant condition itself. Acute symptoms referable to the chest should not be assumed always to represent an inflammatory process and that only. It may indicate secondary involvement by metastatic malignant disease. The implantation of blood stream tumor emboli in the lungs is always a shock which may manifest itself by acute symptoms for a brief period and which might well pass unrecognized, as being of bacterial origin rather than associated directly with the growth. General medical supportive treatment should ever be kept in mind and carried on vigorously in conjunction with the specific treatment of the tumor-bearing area itself.

The opinions of the internists will naturally vary as to the relative values of various types of supporting medication, but whether it be the administration by mouth of stimulants to digestion, inframuscular medication with iron and arsenic or stimulation of body surfaces by means of the quartz lamp, all measures that will aid in the slightest to maintain the patient's general-physical condition at the highest level should be resorted to.

Anaemia is almost constantly associated with malignant disease except in the early stages of growth. It may be increased under the influence of very heavy irradiation. If the irradiation be prolonged, or repeated at intervals, the character of the anaemia changes. The advances in the therapy of anaemias during very recent times may well be taken advantage of. Liver extract and iron are almost as much of a blessing to the medical side of cancer therapy as in pernicious anaemia itself.

There is another reason, and a very legitimate one, for the vigorous use of these aids with detailed attention given therefor. The cancer patient is hanging for support on every possible bit of encouragement. It may be that a great deal of the value to be derived from some of these various measures is a psychological one. It does not matter whether the benefit is physical or mental—the result obtained is justification for the means. This brings us to consideration of another phase of medical treatment which may be opened to some question, yet one which I believe has its advantages if honestly employed.

Specific Medication—Each year brings forth its group of cancer "cures," each supported by its own cancer quack. They all have something to show for their claims, although the

evidence, unfortunately, is always magnified to a very marked degree. An analysis of the many general medical "cures" advocated during the past several years suggests strongly an underlying foreign protein reaction as being common to nearly all of them. Experience with the unusual effects sometimes obtained through the employment of foreign proteins, by virtue of the peculiar systematic reactions which they excite, might lead to interesting speculation as to their value in certain cases of malignant disease.

There are instances in which the systemic reaction of the patient may be stimulated to carry over, when resistance is practically at a standstill, through the intramuscular injection of some one of the simple proteins. It affords, furthermore, in some of the more advanced cases, where palliative relief and moral support only can be given, a reasonable means of carrying the patient along. This might be regarded in some quarters as dishonest practice. It is legitimate to maintain the patient's morale and hope by any such measures, providing the patient's family understands the exact situation and shares in the delusion, if such it be. This must not be interpreted as advising or advocating the intramuscular injection of foreign proteins as an established or approved form of cancer therapy. merely suggested as a possible means of definite aid in certain selected cases and as a legitimate means of aiding, in certain instances, the very trying ordeal of carrying through the last stages the otherwise hopeless case in whom, but for some such resort, the last days would be made very unhappy because treatment had been abandoned.

Some work has been done and a good deal has been written by those who believe that growth is stimulated by an imbalance in body chemistry. Correction has been attempted by direct medication and by alterations in diet to restrict certain salts and increase others. The value of such endeavor is still lacking in confirmation.

Antiluetic Treatment in Cancer.—It has been stated at times that antiluetic treatment of the patient suffering from both syphilis and cancer is contra-indicated, if treatment by irradiation is employed for the malignant growth. This is incorrect. It is true that aggressive treatment by irradiation is a very severe strain on the constitution of any patient. It is likewise true that aggressive antiluetic treatment is a very considerable strain on certain organs. In moderation, on the other hand, it will be found to enhance rather than damage the response to irradiation. The error is often made of carrying on intensive antiluetic treatment first and following this

by treatment of the neoplasm. It is much better to save all possible time by treating the malignant growth as promptly as recognized supporting this by a moderate course of antiluetic treatment and, after the patient has recovered from the effects of the treatment of the new growth, to complete the antiluetic treatment by proper measures consistent with the patient's physical ability to stand the strain. With many new growths, particularly those presenting an ulcerating surface, antiluetic treatment alone is very apt to show an initial improvement in the tumor-bearing This is due to reabsorption, under the stimulus of this treatment, of inflammatory exudates in the tumor bed, and is very apt to be misinterpreted as definite improvement in the growth itself. It will, perhaps, do no harm to emphasize again the possible misleading effects of a positive Wassermann or Kahn reaction. The two diseases may very well coexist. It is always wise, if there is the least uncertainty from the clinical standpoint, to go beyond the positive blood reaction and substantiate the diagnosis of granuloma or neoplasm by histological examination of tissue. The general impression that biopsy may be harmful is unfortunate. The damage incident to the taking of a small piece of tissue is negligible. The time saved in beginning adequate treatment is of inestimable value.

THE FAMILY PHYSICIAN

It is easy enough for the physician who devotes himself largely or entirely to the care of malignant diseases to criticize the family physician's errors, particularly in establishing the diagnosis and getting the treatment under Apart from the special knowledge which his greater experience ought to give him the specialist has the added advantage of viewing the case in retrospect. It would be much better for the specialist to give more time in an effort to further the family physician's knowledge of the many and various problems associated with the large group of malignant diseases. After all, this is the responsibility of any physician who assumes to treat cancer as a special problem. The family physician, on the other hand, must be familiar in a general way with a great number of medical problems and cannot be expected to be intimately acquainted with the many detailed matters incident to new growths in particular. He is too often ignored in the handling of his cancer patient and too frequently the patient is removed from his association. This is not only an injustice to the general practitioner, but reacts, in many instances, to the disadvantage of the patient. The family physician should be kept thoroughly advised throughout

the period of active specific treatment of his patient. All general medical measures, in so far as possible, should be left to him, with proper suggestion and advice. In the first place, he is better acquainted with the patient and with the patient's family and is therefore in a better position to maintain the morale of both. His active participation in this capacity, in the care of the case, permits of his maintaining the proper relation and dignity which is the right of the general practitioner. If the specialist and the family physician keep each other thoroughly advised throughout the period of treatment, each will be able to accomplish his particular part of the work to better advantage and the patient and family will benefit accordingly.

PSYCHOLOGY OF THE CANCER PATIENT

Reference has already been made to the unrestricted use of the term "cancer" and to the advisability of refraining from a too frank statement to the patient. It is difficult to decide just how much should be told the cancer sufferer about his actual condition. Determination of this rests upon many factors. patient who is able to maintain his balance and with whom everything can be discussed frankly and fully at all times is by far the most satisfactory patient to treat. Unfortunately, patients of this type are rare. Usually the manner in which facts are presented to the patient is of greater importance than how much or how little is actually told them. is usually possible to give the patient a fairly clear insight into his condition without bluntly and crudely stating the actual facts in so many words. With a little caution and care he may be left with a rather clear visualization of what the situation is so that he may prepare him-self in various ways and fortify himself to meet the situation without having his morale entirely shattered through severance of that last thread of hope to which all of these patients cling. By the exertion of a little tact. after appraising the situation, one may give a very honest impression to the patient, without disturbing him mentally to the degree that a simple, blunt statement of facts would perhaps do, even in the case of the most stoical,

The term "cancer" should be avoided most carefully at all times. The impression it conveys and the mental picture it promptly brings up are always startling and frequently are most misleading. The cancer patient is inherently an optimist, whether admittedly so or not. Unless his morale can be maintained, therapeutic measures are bound to fail.

Relations with the Family.—In dealing with the patient's family, on the other hand, the confidences should be frank at all times, and never more optimistic than the actual facts of the situation warrant. It is, of course, frequently and perhaps usually necessary, for the mental satisfaction of those concerned, to discuss the patient's problems with several members of the family. It is best, however, whenever possible, to carry on one's relations as physician or surgeon in charge, only with the most responsible member of the family, letting him, or her as the case may be, relay the information to other members of the family and their immediate friends.

In dealing with the family, one must insist upon an appearance, at least, of cheerfulness and optimism, even in the face of adversity, for the sake of its influence on the patient's morale. Reasonable consultations should be welcomed at all times. One is never in a position to guarantee anything in the treatment of any case of malignant disease. Not only for the purpose of safeguarding one's own position in the responsibility assumed, but for the satisfaction of the family as well, consultation should be ample, bearing in mind that too many consultations are apt to confuse the issue and to create an atmosphere of both suspicion and apprehension on the part of the patient.

In dealing with the more advanced stages of the disease, where a limited degree of palliative treatment, only, can be resorted to, it becomes the duty of the physician in charge to safeguard the family against doing many things which they might ultimately regret. There is a very strong tendency at times. under such circumstances, to resort to various questionable measures, some of which may be none too honestly presented to them. must remember that if we are unable to do the patients any good, we are charged with the responsibility of protecting them from harm. Nothing is more deplorable than to take an advanced case of malignant disease from one consultant to another. Adequate nursing care under the general medical supervision of the physician saves the patient a tremendous amount of physical and mental strain.

Palliative Treatment.—Palliative treatment may be variously defined. It may be regarded simply as those measures incident to carrying the patient along to the end. It would be better, however, to consider it as treatment actively and seriously carried out and tending toward the relief and control of symptoms in so far as possible, even while recognizing the inevitable termination of the case. Prolongation of life alone, by various measures, is rarely justifiable unless it is attended by a reasonable degree of relief from symptoms; foremost among these symptoms being pain and the unpleasantness of irritating discharges and foul

مؤمؤ ويتعادي

Fortunately, in connection with controlling ulcerating, discharging and bleeding surfaces, radiation may well be considered a blessing indeed to the cancer sufferer. While opinions may differ as to the relative values of radiation as a curative agent, there is little room for debate as to its value as a most efficient aid in the control of these symptoms. Throughout a period of palliative treatment, most careful attention to constitutional measures and specific therapy, as previously mentioned, should be given, not only on account of its actual value but because of its influence in maintaining the morale of the patient. Palliative operations are too frequently avoided on the assertion that since they are not curative they are not justified. Any reasonable and worth-while procedure to relieve symptoms and add to the physical and mental wellbeing of the patient is justifiable, even though it is in no way curative and even though it does not prolong life. Even the simple use of a post-nasal catheter has saved many a mouth or neck case from the acute distress of dehydration.

Transfusion.—In the treatment of malignant diseases in general, the indications for transfusion are rather clear-cut. As an aid in carrying many patients through serious operative procedures or in maintaining their strength throughout prolonged periods of irradiation where ultimate control of the disease may be reasonably hoped for, the value of a transfusion cannot be overestimated and should be resorted to frequently and liberally. On the other hand, it is very questionable if such a measure should be employed simply to carry on and prolong a course of palliative treatment. There are, of course, exceptions which must be decided upon their individual merits, but as a general rule the value of transfusion in the latter instance is decidedly questionable. Infusions of glucose play an excellent second place to transfusions of whole blood.

Use of Drugs.—In the use of sedatives, the utmost caution should always be exercised. The cancer case usually is of long duration and once started on opiates, it is difficult to withdraw or reduce the amount given. Pain, of course, must be relieved, but a very sharp distinction should be drawn between actual pain and that restlessness which may follow a period of pain during which opiates have been used for its relief. With many ulcerating lesions where pain is dependent more upon the pressure of inflammatory exudates round about the tumor-bearing area than upon the actual pressure of the tumor itself, vigorous

cleansing measures will do a great deal to lessen the need for sedatives. Frequent and careful irrigations with warm, mild, antiseptic solutions are of inestimable value as substitutes for sedatives under such circumstances. The use of heat, especially moist heat, should be employed wherever possible. In fact, al physical measures, such as hydrotherapy, phototherapy and chemotherapy should be used wherever possible to avoid drugs. type of pain experienced in many malignant cases is relieved better by salicylates than by opiates, and it is almost invariably true that the combination of salicylates with codein is far more advantageous than the use of codein or morphine alone. If the medications in the beginning of any of these cases is started properly, there are few patients in whom ½-grain of codein with 10 grains of aspirin will not give relief, even under adverse circumstances, for a period of several hours, and a proper management of such sedative medication will frequently suffice throughout the average case even though the disease itself is not being controlled.

Apart from the immediate period attendant upon a major surgical procedure, and frequently even then, morphine should be carefully avoided and employed only as a last resort for relief in the terminal stages of the disease. If one is extremely cautious in the beginning, there are very few of the terminal cases which require any appreciable amount of morphine. It is much better to increase very considerably the amount of codein given than to change to morphine. The depression and the degree of gastro-intestinal disturbance are less. For the restlessness and nervousness attendant upon a long course of cancer therapy the same sedatives obtain as for other of the chronic diseases. Dependence, however, should be placed more on physical therapy than upon drugs.

There is great temptation, at times, to use cocain regularly on painful surfaces. This is extremely dangerous because the amount of absorption, even over a short period of time, has a deleterious effect on the patient; and if the local benefit is to be maintained, the amount must be increased rather rapidly. It is best to avoid it by not initiating its use. Moist heat will very often accomplish much more satisfactorily that for which cocain is employed.

In the selection of measures to relieve pain and discomfort the simplest are always best. Drugs which depress the patient's morale are to be avoided as carefully as possible.

ENDOCRINOLOGICAL PROBLEMS IN THE GENERAL PRACTICE OF MEDICINE

By M. A. GOLDZIEHER, M.D., BROOKLYN, N. Y.

Rend before the Third District Branch of the Medical Society of the State of New York, at Liberty, N. Y., September 21, 1932.

NDOCRINE discases, as a rule, elicite in the mind of the general practicing physician a recollection of a few striking, but rather rare clinical pictures. He remembers acromegaly, Addison's disease, myxcdema, diabetes insipidus, Fröhlich's adiposo-genital distrophy and, perhaps, a few more syndromes he has read about in textbooks and seen oceasionally. He is familiar with Graves' disease and diabetes mellitus, but because he is so impressed with the general medical aspects of these conditions, he is inclined to overlook the fact that he is dealing with essentially endocrine disturbances. Beyond these two common diseases and the rarer syndromes mentioned before, endoctinology appears to the practitioner as a rather misty chapter of medicine, in which diagnosis is mainly guess work and therapeutic results are usually unsatisfactory. Scepticism about endocrinology is a rather general attitude and there are physicians who do not hesitate to compare endocrinology with astrology or mythology.

Such scepticism was justified in the era following the early discoveries of the function of the various endocrine glands. The results obtained by physiologists in their experimental studies were rather contradictory and if applied for practical purposes most often lead to dismal failure. Yet it is not difficult to see the cause of these apparent contradictions and subsequent clinical disappointment. Our knowledge of the endocrine glands was based upon experiments, done under artificial circumstances and hardly comparable to the conditions which prevail in the healthy and even less in the diseased human body. The progress and recognition of endocrinology was handicapped even more by the lack of active preparations of endocrine glands with the exception of thyroxin and adrenalin. But even the potent extracts obtained were impure and we could not know if the effects recorded were due to one or several hormones or to the presence of biochemically active impurities.

It is only since the discovery of insulin that endocrinology has been making great strides. More recently the active principles of the anterior and posterior lobe of the pituitary, of the ovary, the parathyroid gland and the adrenal cortex, have been isolated. Some of these hormones have been purified to that extent that they are available now in crystalline form. The improvement of experimental surgical technique has also materially added to our knowledge; it became possible to study the behavior and reaction of animals after re-

moval of these glands, not excluding even the pineal and pituitary which are so well hidden in the skull. By comparing the changes observed in operated animals and the effects obtained by administration of the various hormones with clinical observations, practical information was gained and the whole aspect of endocrinology completely changed. Endo-crinology today is one of the most exact branches of medicine and we diagnose endocrine disturbances and localize the diseased gland just as definitely as, for instance, we ascertain disturbances of renal function. The general practitioner has little difficulty in the diagnosis of renal insufficiency either in acute or chronic kidney lesions. The type of kidney lesion, the state of retention, and concomitant metabolic disturbances, however, cannot be identified in the office of the doctor or at the patient's home. Such studies require the facilities of a hospital, and particularly of a competent laboratory. The exact determination of the nature and severity of an endocrine disturbance also requires similar facilities and the efforts of special training. Yet it is up to the general practitioner with his necessarily more limited armament, to detect those cases, the true nature of which can be ascertained only by exact and often painstaking studies.

When should the practicing physician suspect that the underlying disturbance in his patient's ailment is of endocrine nature? It is impossible, of course, to answer such a question with a general statement, although there are some fundamental rules well worth to be borne in mind. Every physician knows that the urine should be examined for the presence of sugar in case his patient reacts too severely to an otherwise common or minor cause, or if improvement is unduly delayed in spite of what seems appropriate therapy. In other words, diabetes mellitus should be considered to account for the unwarranted aggravation of symptoms or the lack of healing tendencies. It seems logical to assume that other metabolic disturbances based upon disfunction or insufficiency of some endocrine gland may also account for similarly striking observations. This is borne out by actual clinical experience and illustrated by the following few examples.

The first case is that of a physician, a powerfully built, very active man, who was suffering from an annoying skin lesion. He was in the care of a good dermatologist and also seen by other physicians. His condition persisted for almost a year in spite of varied local treatment, including Array. He finally submitted to an endocrine examination which revealed a rather

marked state of hypothyroidism. His skin condition cleared up rapidly upon administration of thyroid, combined with the same treatment which had been previously unsuccessful.

Another instance, is that of a woman in the early forties who was ailing with a fairly severe anemia of the hyperchrome type with numerous megalocytes, yet no other evidence of pernicious anemia. She also suffered from a spastic colon and chronic constipation. She has been seen by many prominent men, both in this country and Iron, arsenic, copper, liver and ventriculin were given in large amounts and in every possible way, with unsatisfactory results. treatment of her intestinal condition was equally unsuccessful. Diagnosis of hypothyroidism was made on the basis of a low basal metabolism; thyroid treatment was instituted with the result that the anemia cleared up completely without any additional medication and the patient is spared the ordeal of daily enemas and physics.

It would be easy to enumerate similar cases, which all prove but one point: that patients whose ailments are refractory to usually successful medication, may do well on administration of the proper endocrine therapy, the nature of which depends upon the type of underlying endocrine disturbance. I want to emphasize, however, that although the incidence of endocrinopathy in obstinate or refractory conditions is great, we do encounter such cases without any demonstrable endocrine lesion.

A second guiding thought which may prove helpful in the discovery of veiled endocrine conditions is also better illustrated by a specific case. A young girl, who happened to be one of our laboratory technicians, complained for quite some time of gastric symptoms and particularly of pains in the epigastrium. These pains set in usually after meals, occasionally as late as three hours after ingestion. She was losweight and showed increasing anemia and nervous tension. Thorough gastroenterological studies including analysis of gastric juices, x-ray pictures and G. I. series were perfectly negative. Symptomatic treatment was of no The fact that gastro-intestinal symptoms persisted without any demonstrable anatomical lesions made us suspect an endocrine disturbance. A sugar tolerance test was done and revealed a normal fasting sugar of 95 mg. which increased 30 minutes after the intake of 100 gms. of sugar to 100 mg. One hour after the test meal, there was a drop to 80 and after the second hour a further drop to 70 mgs., instead of the expected rise. This paradoxical behavior of the blood sugar curve ceases to be mysterious if we remember the physiological relations of the endocrine glands instrumental in the regulation of carbohydrate metabolism. The intake of sugar is followed by an early rise in blood sugar which seems to depend upon a liberation of sugar from the liver. This reflex phenomenon is soon followed by the appearance of the resorbed sugar in the blood. A rising blood sugar acts as the physiological stimulus of the pancreas and elicits a discharge of insulin. If this would occur without any further regulation, the blood sugar would fall to a level which is not compatible with life. The regulation provided for to counterbalance the effect of insulin, consists of the discharge of adrenalin from the adrenal glands. This has been shown conclusively in experiments in which the susceptibility of experimental animals towards insulin increased by ligature of the adrenal veins or any other procedure that prevents discharge of adrenalin. The insulin-hypersusceptibility after adrenalectomy or other comparable procedures is such that the animal dies in hypoglycemic shock from a dose of insulin which was previously tolerated without untoward effects. In view of these considerations the phenomenon observed in our patient indicates one of two conditions: Hyperfunction of the pancreatic islands and subsequent excess of insulin production or hypofunction of the adrenal, with lack of adrenalin discharge. Hyperinsulinemia is accompanied by symptoms of faintness, dizziness, perspiration, or in other words, those of a mild insulin shock. In the absence of these symptoms the diagnosis of hypoadrenalism was made. The patient is now doing well on administration of ephedrin 3/8 gr. t.i.d. This case illustrates the thought that symptoms which are not substantiated by anatomical changes must be looked upon as functional disturbances caused either by neurological or endocrine conditions.

It is impossible to survey even in a most abbreviated form all those ailments which the general practitioner encounters in his daily work and in which endocrine lesions should be considered. I want to sketch only some of the most important points: most important because they are so common and yet so infrequently recognized.

I have already illustrated the question of anemia with a few examples. It is known since Kocher's time that the thyroid gland influences the formation of red cells. Kunde, Green and Burns, stated in their recent study on experimental hypothyroidism, that the red blood cells appear larger than normal, yet their number decreased, hence the hyperchrome type of t hypothyroid anemia. These authors also obserthe development of polycythemia with incre' hemoglobin in the early stage of experim hyperthyroidism. In the later stages, they the development of a progressive sec anemia with smaller red blood cells and ; stronger decrease in hemoglobin content and consequently a color index of less than one. Anemia occurs also in other endocrine conditions, particularly in hypofunction of the adrenal glands, for

instance in Addison's disease. Pituitary cachexia is also accompanied by sever anemia; but other clinical symptoms of these conditions are so much more significant that the concomitant anemia does not present particular diagnostic difficulties.

Gastro-intestinal disturbances are among the most common symptoms of endocrine disorder. Pain in the stomach, flatulency, diarrhea or constipation and poor appetite are complained of by most patients suffering from Addison's disease. I mentioned before a mild case of adrenal hypofunction with symptoms suggestive of peptic ulcer and also referred to the hunger pains occuring in hyperinsulinism. Constipation is perhaps one of the most common observations in endocrine patients. Of course, there are many other factors responsible for constipation, but if symptomatic treatment fails to relieve an obstinate case, veiled thyroid or pituitary failure ought to be considered. The opposite of this ailment: loose bowels are frequently observed in Graves' discase. They are also conspicuous in some of the more involved neurovascular conditions in which disturbance of the sympathetic or vagic innervation is often demonstrable. Vonuting or nausea is frequently produced by adrenal failure, yet it assumes really menacing proportions in acute hyperfunction of the pituitary in pregnaney. Hyperfunction of the posterior lobe with subsequent water retention and oliguria is often successfully counteracted by administration of thyroid, while acetonemia and acidosis due to anterior pituitary overactivity call for intravenous glucose therapy and alkalis.

The sphere of genital function, both in males and females is another fertile field for discussion. It has been shown that the sperma of a healthy male remains motile over a period of from 8 to 10 hours if kept at body temperature in a moist medium. Untimely decay of the sperma with loss of motility is not rare in cases of sterility. Some of these patients are hypothyroids, others hypopituitaries. Adequate therapy increases the viability of their sperma and restores the possibility of fertilization. Disturbances of the sex sphere dependent upon diseases of endocrine glands are particularly common in women. Without going into details which pertain to the field of the gynecologist, we can say that amenorrhea, if not due to pregnancy, is usually due to failure of the anterior pituitary lobe, and can be cured by organotherapy. Dysmenorrhea is also quite often the result of pituitary failure and if this is the case, administration of anterior pituitary proves to be successful. In patients who do not show evidence of pituitary disfunction, administration of follicular hormone should be resorted to in order to bring about menstruation at its proper time and prevent the premenstrual disorder which in young females is so often followed by psychoneurotic troubles. Excessive menstruation or abbreviated intervals are sometimes successfully eoped with by the administration of corpus luteum. Oral administration of these substances is not always effective and therapy by hypodermic injection is preferable. These statements sound rather commonplace, yet it seems that organo-therapy of menstrual disturbances is still a considerably misunderstood and neglected field. There is another group of less common but theoretically more interesting cases that are not relieved by organotherapy because organic changes, such as large or multiple follicular cysts, lutein cysts or granulosa cell growths are present in the ovaries. Persistent excessive production of follicular hormone by follicular cysts elicits glandular hyperplasia of the endometrium. This condition is likely to recur even after surgical removal of the spongy hyperplastic endometrium and in spite of copious lutein body therapy. Much better results are obtained by radiation or surgical correction of the ovaries. Another interesting symptom complex is produced by the granulosa cell tumors of the ovary in women past the menopause. Such tumors, although often too small to be recognized by normal examination, elicit diffuse hyperplasia of the uterine body. Not a few of these women have been subjected to hysterectomy for suspected uterine eareinoma. X-ray therapy of the ovaries or removal of the comparatively benign neoplasm, radically disposes of the alarming symptoms.

We have discussed sterility before from the point of view of male endocrine disorders. Obviously, thyroid or pituitary failure of the woman ought to be suspected in eases of sterility in which anatomical changes of the female genitalia are not demonstrable and the male partner is not to be blamed. Organotherapy, supplying the deficient hormones is apt to remedy the situation. My own limited observations are corroborated by Rowe's experience which is the largest in this field and whose results are quite encouraging.

We shall discuss now the relationship of metabolic disturbances to endocrine disorders. Let us take first obesity. Obesity unquestionably is often due merely to overindulgence in food and lack of sufficient physical exercise. Yet in many other cases it seems to be constitutional and familial. In the majority of the latter disturbances of metabolism, based upon disfunction of one or several endocrine glands are revealed by sufficiently thorough examination. We need not discuss hypothyroidism, as the relation of this condition to obesity is too-well known. I am sure, however, that all of you have seen obese patients who did not lose weight in spite of a rigid diet and liberal thyroid medication. Thyroid treatment could not be given, or had to be interrupted in other eases due to cardiac symptoms. Most of these patients were suffering either from failure of the pituitary gland or excessive function of the

adrenal cortex. The latter condition is rare, occurs mostly in females and is characterized by simultaneous amenorrhea and hirsutism. cause is either a tumor or bilateral hyperplasia of the adrenal cortex. We reported some time ago on such a case in which the diagnosis of cortical hyperplasia was subsequently verified at operation. Removal of one of the tremendously enlarged adrenals was followed by a loss of 145 lbs., decreasing the patients weight from 330 to 185 lbs., in the course of 8 months without any diet or medication. Another similar case came recently under our observation and surgery accounted for practically identical results. In pituitary obesity deficiency of the anterior lobe and bilobar failure must be distinguished. The anterior lobe according to recent investigations produces several hormones, one of which is active in the oxidation of fats whereas the other stimulates the thyroid and simultaneously increases the specific dynamic action of proteins (Anselmino & Hoffman, Paul, Crow, Janssen). Excessive deposit of fat due to insufficient function of the anterior lobe may be combined with failure of the posterior lobe resulting in the retention of salt and Such patients do not lose much weight even upon administration of enormous doses of anterior pituitary. Results are obtained only by restriction of salt and water intake, administration of both anterior and posterior pituitary products combined with intermittent thyroid medication.

The counterpart of endocrine obesity is endocrine leanness. There are patients which remain constantly underweight and do not respond to high caloric diet. Organically there is nothing the matter with them. Functionally, however, they are nervous, irritable, asthenic and easily fatigued. This condition is not properly clarified as yet, probably because of its variegated pathogenesis. Recent work, carried out by Jahn in v. Romberg's clinic has added materially to our knowledge of asthenia and illustrated the variety and extent of disturbances in intermediary metabolism characteristic of these cases. Rapid and extreme changes in the acidbase equilibrium are particularly outstanding. Loss of acid by hyperventilation of the lungs, urinary elimination of acid phosphates, and gastric hypersecretion occasionally produce alarming states of alkalosis which manifest themselves in the form of headache, dizziness, nausea and vomiting. patients are frequently subject to asthmatic attacks and various allergic manifestations. During such attacks increased formation of keton bodies has been observed and interpreted as a compensatory process against the alkalosis. Massive elimination of alkaline phosphates with the urine in this stage seems to serve the same purpose. The result of these processes, however, is often overcompensation into a stage of acidosis with its well-known symptoms. These are rapidly disposed of by administration of glucose, the effect of which can be biochemically gauged by the disappearance of the excessive keton bodies of the blood and their substitution by increasing lactic acid.

Disturbances of the peripheral circulation such as cold, clammy, bluish hands and feet are often met with in these patients. They are apparently due to dilation of the small venules (Kroetz), although lability of the capillary system and arterioles also plays its part. The low carbondioxide content of the blood seems to be one of the main responsible factors in this peripheral circulatory disturbance (Gollwitzer-Meyer). Palpitation of the heart, moist skin, tremor, and occasionally stare are often present and likely to suggest a thyrotoxic condition which we are able to rule out on the strength of a normal or low basal metabolic rate.

A better understanding of the asthenic conditions can be arrived at if we compare these cases with some of the extreme types of endocrinopathies, in which the symptoms of asthenia and loss of weight dominate. I have reference to Simmond's pituitary cachexia and Addison's disease. Milder degrees of pituitary and particularly of adrenal failure are likely to produce a much less striking picture, which however, is characterized by marked fatigue and leanness. According to Rowe, 93% of cases with adrenal lesions show such symptoms, while they are in evidence only in 48% of pituitary disease. An even higher percentage, that is 59%, of Rowe's thyroid patients gave similar complaints. Some of these were hypothyroids with low basal metabolism, yet they were definitely underweight and did not show any of the mental sluggishness which is thought to be typical of thyroid failure. It stands to reason that sensible treatment cannot be instituted before the cause of the disorder has been ascertained. This is the more important because these cases lend themselves particularly well to endocrine therapy. Pituitary failure is combated by administration of anterior pituitary substance; adrenal cases and those with a high basal metabolism by the administration of interrenin, the adrenal cortical hormone and hypothyroid cases by thyroid medication. Some of these patients respond well to stimulation by radiation, and particularly to treatment with Bucky's Grenz rays.

Disturbances of water metabolism, expressed by polyuria and polydipsia are particularly annoying to the patient. They are tortured by thirst and their sleep is often interfered with by nocturia. Most of these cases are obese and may or may not show retention of salt. The controversy is still going on whether the underlying pathology is a hypofunction of the posterior lobe of the pituitary as I have stated first in 1913, or some cerebral lesion in the subthalamic or in-

fundibular region. From our purely clinicotherapeutic viewpoint, however, the different concepts of pathogenesis do not matter because the only effective treatment of these cases is unquestionably that with posterior pituitary extracts. Oral application is also efficacious, but too large amounts of the expensive substance are required. Subcutaneous administration may cause excessive peristalsis and abdominal cramps. The method of choice is the intranasal application. Instillation of a few drops or a spray with surgical pituitrin produces the desired effect. We had quite a number of these patients in our endocrine clinic and we were successful in decreasing both the daily intake and output of water by this method. Thus in one of our patients, a woman aged 40, the daily intake averaged 140 oz. with commensurate output; after two weeks treatment the intake and output decreased to from 50 to 60 oz, a day. This case was the more interesting because the patient had been in the care of our diabetic clinie with her diabetes well under control. She was referred to our clinic because polyuria still persisted. Several other patients who came with similar complaints, were markedly obese and suffered from severe headaches. Since their disturbance of water metabolism has been controlled by pituitary treatment, and salt poor diet, their headaches disappeared and they sleep well again. Their weight has been also materially reduced during the same period.

Disturbances of salt and water metabolism sometimes account for rather queer symptoms. Thus a young girl who came under our observation for amenorrhea, complained about fainting spells which occurred whenever she attempted to bathe in the ocean. She also mentioned swelling of her lips in case she ate ice cream, and swelling of hands when she touched cold water. These angioneurotic symptoms disappeared after six weeks of salt restriction and pituitary therapy. Her menstruation also returned.

In another middle aged woman with mild menstrual disturbances there was an 8 months history of migrating swelling of the joints, and adjacent soft parts. After all other therapeutic means had been unsuccessfully attempted, patient came under our care. She proved to be another bilobar pituitary failure and was given the same pituitary treatment and salt poor diet. She had only one more attack on one finger, lasting a single day which ceased without migrating. Patient is symptom free ever since.

In another large group of endocrine disorders nervous irritability and asthenia are coupled with disturbances of psychic nature. It has been my fortune to see among other cases that of a physician, 40 years of age and quite powerfully built. He used to be a football player at college. He complained of fatigue, sluggishness, irritability and admitted inferiority complexes. He had seen

quite a number of physicians and specialists of neurology, who concurred in the opinion that his was a case of neurasthenia. Endocrinological investigation showed an anterior lobe failure with some apparently secondary hypothyroidism. His "neurasthenia" improved rapidly under organotherapy and administration of Bucky's Grenz rays.

The occurrence of psychoneurotic symptoms is much more frequent in endocrine cases than in patients suffering from other conditions. Rowe reports upon a series of 500 endocrine cases, out of which 102 that is 20.8% showed psychoneurotic disorders. In a control series of 500 nonendocrine patients only 14.2% showed comparable symptoms. Out of the 500 endocrinopathies, 185 were pitnitary cases with 22 psychoneurotics, that is 10.9%. The thyroid group of 116 had only 15 psychoneurotics equalling 9.3%. The gonadal group of 125 cases gave the largest number in this series of 38 which is 30.4%. There were also 15 adrenal and 15 polyglandular cases out of which 13 and 14 respectively were psychoneurotic, making a percentage of 86.7 and 93.3 respectively.

After reviewing some of the more common endoerine disorders, we have to face a crucial question: how to diagnose these conditions and on what basis are certain symptoms ascribed to the failure or excessive function of one particular gland?

Endocrinology is but a special line of clinical medicine in which the same methods are practiced that prove successful in the diagnosis of other medical conditions. The general appearance of the patient, his type of fat distribution, inspection of the skin, hair and teeth, and first of all a carefully taken history often give sufficient reasons to suspect an endocrinopathy. After such a tentative diagnosis has been arrived at, there are two ways open to follow. One is the oldfashioned empirical way of alternatingly administering to the patient various glandular products in order to determine the cause of the disease by the effect of therapy. This procedure may work sometimes, but more often fails and certainly cannot be considered to be scientifically exact. It is so much safer for the patient to approach his condition by a thorough endocrine workup which usually identifies the gland responsible for the elinical symptoms. I would like to briefly present the systematic procedure which we have instituted for the study of these cases in our endocrine clinic.

Determination of disorders of the thyroid gland is based largely upon the basel metabolic readings. We feel that hyperfunction of the thyroid cannot be diagnosed in the absence of an increased basal metabolic rate, nor ean hypothyroidism be claimed without low basal metabolic readings. The rate of blood cholesterol usually de-

creases with accentuated thyroid functions and increases in hypothyroid conditions. Diagnosis of anterior pituitary failure is made as a rule on the basis of high blood uric acid, decreased or absent specific dynamic action and marked lymphocytosis. The significance of increased uric acid in the blood has been stressed first by Rowe. In our experience which at present covers several hundred thoroughly studied cases, the average uric acid in pituitary disease is well over 4 mgs., whereas the normal figure is below 3. The increase in uric acid is sometimes quite remarkable and seems to be rather constant. Most important is the lack of specific dynamic action of proteins which according to Plaut, Artundo, Bernhard, Anselmino and Hoffman and others is an almost constant symptom of pituitary failure. The significance of this sign is borne out by increase of the special dynamic action following pituitary medication. The technique of the test is very simple. The patient, after completion of the basal metabolic test, is given a test breakfast, which consists of the white of three eggs, a thin slice of toast and a cup of plain tea. Two hours later a second metabolism test is done; the difference between the two readings expresses the specific dynamic action, that is the increase in the rate of metabolism, due to the stimulating effect of proteins. Other authors have used large amounts of meat as a test meal, but I believe that the test is finer and more reliable if a comparatively small amount of protein is given. The specific dynamic action of normal persons ranges anywhere between 15 and 35% after ingestion of the test meal mentioned above. In most of our several hundred pituitary cases the figures were well below the lower limit of 15. I would like to call attention, however, to two cases, in which a high specific dynamic action was obtained, and which proved to be pituitary neoplasm. It might be in place to emphasize in this connection that diagnosis is facilitated by ophthalmological and x-ray pictures of the skull only in case the pituitary disorder is due to enlargement of the gland. Another valuable test in pituitary failure has been described by Schellong: examination of blood pressure before and after exertion. A fall of pressure on exertion is always demonstrable in Simmonds cachexia and is also noticeable in and suggestive of minor degrees of anterior pituitary

failure. The drop does not always appear immediately, but becomes apparent only after a few minutes. The fall in pressure after exertion manifests itself as a rule only in patients with normal or slightly lower blood pressure. Schellong's test is negative in cases of pituitary disease associated with hypertension.

The determination of posterior pituitary failure is based mainly upon the outcome of the salt test. We measure the water and salt output on a standard diet over a period of 24 hours. On the next day, after breakfast, patient is given 10 grams of salt with half a pint of water. Water and salt excretion in the next 24 hours is again determined while patient is repeating the same food and water intake as on the previous day. The majority of our pituitary cases thus examined showed a retention of salt while diuresis and salt elimination was increased only in a few of the cases.

The sugar tolerance test gives information primarily as to the function of the pancreas and adrenals, although the outcome of the test might be influenced also by disorders of the posterior pituitary and thyroid. I readily admit that diagnosis of adrenal cases with the exception of true Addison's disease is quite complicated and requires, particularly thorough study of the case history and physical symptoms as well as numerous laboratory tests. Among the latter I would not like to miss study of blood pressure under varying conditions and particularly after administration of adrenalin. Adrenal insufficiency must be thought of in cases of chronic fatigue, coupled with lymphocytosis, low blood sugar, somewhat increased blood nitrogen, low blood pressure, sluggish response to adrenalin and high sugar tolerance. Paradoxical blood sugar curves with alimentary hypoglycemia are of particular significance. Real adynamia, loss of weight, anemia, gastric symptoms and pigmentation complete the picture of true Addison's disease, but while the latter is rather rare, mild cases of adrenal hypofunction are much more common and go_about unrecognized and untreated.

If, however, the possibility of glandular disease receives consideration, guided by the principles discussed in this paper, systematic investigation is likely to establish the cause of the ail-

ment and remedy its symptoms.

TOXIC ACTION OF METALS IN ALOPECIA AREATA

By C. N. MYERS, Ph.D., Sc.D., BINFORD THRONE, M.D., AND JEROME KINGSBURY, M.D., NEW YORK, N. Y.

From the Stuyvesant Square Hospital, New York

FOR many decades bald spots have been the source of much concern to men, women and children. These spots are more technically known as alopecia or alopecia areata; or, under more distressing eircumstances, the condition is spoken of as alopecia totalis. This disturbing, but not serious clinical symptom has been the subject of continued research on the part of endoerinologists, internists, and dermatologists for many years, and has led many beauty specialists and quacks to prey upon the unfortunate victims.

It is not our purpose to discuss the various theories in regard to the etiology of alopecia areata. On the other hand, it is our intention to give a short discussion of our findings from the biochemical point of view and its relation to metal retention. The elinical factors will be found in a later article. Much detailed study has been carried out in connection with the medical aspects of this subject, but they will not be included in this article for the reason that effort is being made to present the data physiologically.

present the data physiologicany

In presenting this data at this time, endeavor is made to call attention to the disease and give adequate information so that an intelligent approach to the proper diagnosis may be obtained.

Alopecia areata is a disorder characterized by sharply circumscribed areas of total baldness. The affection occasionally involves regions other than the scalp, and in rare instances gives rise to an alopecia universalis. The bald patelies suddenly develop on apparently normal skin, and there is a very marked variation in the size, shape and locality. The scalp, the eyebrows, the bearded region, and even the body may show areas in which the hair has completely fallen out. falling out of the hair sometimes is gradual lasting over several days and, occasionally, the spots come out within apparently a very few hours. At the margin of the alopecia lesions the shafts may exhibit atrophic changes. Near the mouth of the follicles so-called "exclamation point" hairs may become loosened and painlessly extracted. The patches occur in all ages of individuals and in both sexes.

The exact eause of alopecia areata has been unknown, although it seems to be more prevalent in the earlier decades of life and occurs with about equal frequency in both sexes. The neurotic and the parasitic origins have received consideration but, etiologically, no evidence has been evolved.

A sudden fright or falling from an unusual height are instances which have caused marked shock symptoms. It is our belief that shock symptoms, of whatever nature they may be, produce the necessary stimuli to complete a diseased

process which has already been initiated. It is from this angle that consideration has been given to the fulminating influence associated with metaholic disturbances.

The long series of studies which have been carried out by us in relation to the action of metals on certain clinical symptoms, have led us to believe that our attack has been directed in the right direction.

From the medical point of view, it has not been denied that endocrine disturbances may even be associated with the presence of metals in the system. For twenty-five years or more, theories have been advanced indicating that pituitary disturbances may play a part, but no satisfactory elinical study has been made showing definitely that endocrine disturbance is a factor concerned with the appearance of alopecia areata in all cases.

On an emperical basis, various types of pituitary extracts have been employed. In so far as information has been ascertained by us, there is no available evidence appearing in these articles showing by laboratory examination that the pituitary is involved. Every elinician is aware of the promiscuous use of glandular therapy. However, proof of the necessity for its use is quite regularly the situation concerned in many of these eases. In our investigations, sufficient glandular therapy has been used, but in most instances with negative results. In the three patients that have failed to respond in our studies, no definite glandular disturbance was associated with their condition, as shown by the results of months of careful laboratory examinations under controlled con-

Our earlier therapeutic approach consisted in the application of anterior pituitary. Our observations had led us to believe that a very small number of cases fall in this group; whereas our present studies have shown us that a great majority of patients have been associated with a metallic retention.

From the point of view of endocrinology, and through the contesy of Dr. Allen Winter Rowe, of Boston, many very painstaking examinations have been made. In this relation there have been three cases which were very resistant to all types of treatment. Our facilities were insufficient for further study of these ambulatory patients and Dr. Rowe very kindly consented to study the patients who were placed in the hospital for continuous observation. His experiments indicated that it was correct in assuming that pituitary disturbances were not involved. Before having come to us these individuals had submitted to pituitary treatment with no success. Mention is made of

these three cases to indicate that pituitary deficiencies are comparatively rare as far as alopecia areata is concerned. Without adequate information of the presence of either hypo or hyperpituitrism, it is readily understood that such glandular therapy would be of very little value.

In the group of patients which have been studied, a small boy, six years of age, fell out of a second story window, with the result that a total alopecia developed within one week. It should be pointed out at this time that our experiences have not indicated that this shock alone was the cause of the alopecia. Further examination of this child showed the presence of unusual amounts of arsenic and lead. The child was checked for other physical abnormalities such as eye strain, diseased tonsils, and endocrine disturbances. It is our belief that this case represented an accumulation of toxic reactions. The sudden disappearance of hair was brought on by the shock, which served as a fulminating influence.

Our previous investigations have shown the rapidity with which metals accumulate in the reticulo-endothelial system. This influence is then transferred to the vegetative nervous system, which in turn may produce very marked reactions of various kinds. These abnormal stimuli may then cause disturbances of the various glands and result in the abnormal basal rates which have been observed by us. It has been our belief that a damaged reticulo endothelial system produces very marked physiological changes upon the various functions of the body.

In Germany there have been several instances in which either girls or boys have developed alopecia areata in somewhat epidemic form. This is easily explained on the basis of new construction of the water supply, or the new buildings. Until recently lead pipe had been a very ordinary mode of conducting water supply into institutions and even into private dwellings. It has been shown that water with a high carbondioxide content, flowing through even 20 feet of lead pipe, may dissolve sufficient lead to produce chronic plumbism. This last situation is mentioned to indicate the importance of environment in its relation to this disease.

Foods, drugs, and water supply offer very easily accessible sources of metals. The prevailing methods of spraying fruits, dusting vegetation, and destroying mosquitoes, readily explain why arsenic and lead should be looked for in association with unusual and obscure clinical symptoms.

Alopecia areata does not confine itself to any one strata of civilization. With this factor in mind, it was decided that a careful study of the patients should be carried out from the point of view of blood chemistry and metallic retention.

In recent years thallium acetate, in spite of its very toxic action, has been employed to a very considerable extent in the treatment of ringworm infections of the scalp. In the employment of thallium epilation it has been noted that the hair of the patient being treated completely falls out, and that the individual hairs conform to the "exclamation point" appearance. This would indicate that possibly metals may play some part in the production of the clinical symptoms in alopecia areata, and in turn it suggests the possibility that some of the common metals may have a role in the causation of this disease. In previous reports by us it has been shown that metals have a marked effect upon the reticulo endothelial system, the vegetative nervous system, and the general blood picture of individuals. Also, there is a distinct deposition of these metals in the reticulo endothelial system.

In confirmation of the suggested ideas, it is important to report the investigations of Pardo Castello, who believed that the alopecia produced by thallium compounds, corresponded to the experimental production of alopecia areata in man.

The presence of "exclamation point" hairs in alopecia areata has been known for a long time, and Abramowitz has stated that they are also found following the administration of thallium acetate.

It has been shown by us, in a great many instances, that arsenic has a strong predilection for the keratin tissues and, accordingly, Wilcox, and Althausen have pointed out that arsenic exists in considerable quantity in the hair, skin and nails. More recently a very extensive investigation has been carried out by Schwartz, who has examined the hair and nails of a great many individuals. He finds that there is a variation in the hair depending upon the part of the body from which it is taken. The same is true in respect to the nails.

If arsenic and lead are deposited in the bone marrow, or any other part of the reticulo endothelial system, it is very probable that this passive distribution of the metals will produce a marked effect upon the general vegetative reaction, the peripheral organs in particular.

The influence of such drugs as suprarenin, pilocarpine and atropine, although different in their vegetative action, have been studied by Myers and Müller in their relation to the deposition of arsenic in the various tissues of the body; and these investigations show that there finally results a physiological action, such that the endothelium will show a decrease of cellular perme-The selection of these drugs was made because of the marked effect which they can produce upon the distribution of arsenic in the entire involuntary nervous system. Pilocarpine increases cellular activity and cellular permeability. renaline produces the reverse action. Consequently, it can be assumed that an injection of pilocarpine would change the vascular system and probably the tonus of all organs and tissues into a state of increased activity.

It would be expected that a larger amount of arsenic would pass from the blood into the organs because of the higher permeability of the vascular endothelium and all cells and tissues of vessels and capillaries through which arsenic naturally finds its way from the circulation into the organs Consequently, it was decided to employ the capillary microscope for examination of these areas of alopecia areata, and it was found that these capil-

been included in our abnormal metabolic group As indicated, a clinical examination alone is not regarded as adequate to fix the metabolic value

As a result of these tests being carried out in the entire group of patients, abnormal basal meta bolism was found in 24% of the males and 37 09% of the females, and there were twice as many abnormal minus findings as there were plus findings. See Table 1

laries were either markedly contracted or were not visible at all

Inasmuch as there had been a permeability of the metals into the slim and hair, it was decided to employ suprarenin in 1 1000 solution and to stroke the mucosa of the lower concha with a probe. In cases of sympathicotomia a red line will develop which stands out prominently on the contracted buckground. The reaction is considerably prolonged, the blanched area being present as long as forty minutes.

In order to determine by vasoconstrictor action the relation of the tonicity of the arterioles of the alopecia areata, and the arterioles of other parts of the body, a drop of one-tenth per cent solution of histamine was applied to the scalp on the hairless area and on the flexor surface of the forearm, which resulted in the production of a wheal. The wheal of the scalp was only about one-fourth the size of the wheal on the forearm, while the fire was more extensive on the scalp and less extensive on the flexor surface. In normal individuals the size of the wheal is the same in each location

Basal metabolism tests were carried out according to the methods of Benedict and DuBois The results used have been selected on the basis of the general trend of the basil rate rather than upon specific values Values above +5 and -5 have

Basal metabolism examinations were employed because of the fact that it is our opinion, based on extensive studies of tests in skin diseases in general, that abnormal results may be expected when pathological amounts of metal have been observed in these patients. The effect of metal will produce a toxic reaction and, therefore, this action will manifest itself in the metabolic rate of such patients.

In studying patients who have received injections of metals, it has been found that there is a marked reduction in the basal state. This is demonstrated quite readily when neurosyphilities are subjected to these tests. It is understood that this type of patient has undoubtedly received arsenic, bismuth, or mercury, sometime during the period of their treatment. Our experiments dealing with this subject are still unpublished.

Blood counts were carried out on all of the individuals reported in our preliminary discussion, and it was determined that there was a relative lymphocytosis in 71 83% of all the cases studied at that time. In making the differential white blood cell count, a value below 60 for the polyneuclear cells was considered as showing lymphocytosis, and also was indicative of an intoxicating influence. In every case a complete blood count was made with results which are indicated in table 2.

TABLE 2. Differential White Cell Count in Alopecia Patients.

Investigations of Müller and Myers have shown that metals produce a distinct reaction upon the lymphocytic mechanism. This indicates that a disturbance of the vegetative nervous system has taken place. Our results in connection with alopecia areata confirm their findings.

During the course of our research extensive studies showed that there was a decrease of leukocytes in the peripheric vessels which corresponded to an increase of leukocytes more particularly of the neutrophil polyneuclear type in the splanchic area. These changes, in the distribution of leukocytes, were observed following the intravenous administration of arsenic. In many instances the involuntary nervous system caused not only the acute blood changes but also the manifestation known as symptoms of angioneurotic shock.

Chemical examination of the blood for sugar, chloride, urea and uric acid was carried out in 454 cases. The so-called metallic blood picture, previously described by Myers and Throne, was found in 21% of the original cases reported.

A study of the urine was made for the reason that it shows the elements which are being excreted. If these elements appear in abnormally large quantities, it is evident that they must have been circulated throughout the tissues and the blood stream previous to excretion. It is our belief that, in making a study of the marked retention, examination of the urine and blood will give the most satisfactory results. In some instances there may be an absence of metal in the blood and urine indicating that there has been a tissue retention. It is for this reason that we have employed eliminative treatment according to the diagnostic procedures previously described by us.

In carrying out the examination for arsenic and

lead in the urine, the patient was requested to bring a quart specimen from which sufficient material was taken for the arsenic determination. To the measured remainder 50 c.c. of concentrated ammonia were added and then allowed to stand. The lead determinations were made essentially in accordance with the methods of Fairhall. The chemical examination of the urine was carried out routinely, and the results for arsenic expressed in micromilligrams of arsenic per 100 grams of dried specimen, and micromilligrams of lead per liter of urine.

The purpose of separating them into these groups is of value in presenting a statistical incidence of the disease for the various decades studied. The number of patients, together with the metal findings is found in the various tables. However, it will be observed that in some instances arsenic was found while in others lead only was observed. The number of patients who showed no metals at all is presented in the last column. For instance, in table No. 1, 300 patients were studied, and of this group. 198 were carefully examined showing that there was 44.94% with arsenic, 19.19% with lead, and 11.62% with both of the metals present. The total percentage of specimens showing metals is 75.75%. The detailed analytical findings are given in table No. 3.

TABLE 3. Urine Determinations for Lead and Arsenic.

Everyone familiar with the subject of spray residues and other metallic contaminations, is aware that there are seasonal variations; e.g., one may expect that the retention of metal will be much greater during the colder periods of the year when general metabolism is somewhat diminished. Exposure to metals, and their retention, is closely related to meteorlogical conditions.

Likewise, the effect of alcoholism, bacterial infection, focal infection, and a great variety of factors of this character markedly influences the excretion and retention of metals.

To avoid any possibility that our original group of patients may have been selected without any consideration of seasonal variation, several additional groups were set aside for examination at different periods of the year, and also at different years. In the original report by Feit, Throne and Myers, the patients were studied from the point of view of basal metabolism, metal content, blood chemistry and the effect of metals on the vegetative nervous system.

Table 4. Table No. 4 shows the same data as found in table No. 3 except that it was taken at another season of the year. It would appear that possibly there is a slight diminution of cases showing metals in this group. These patients represent warm weather examinations.

Very frequently clinicians have been concerned about the amount of metals which may be ex-

pected in patients suffering with some forms of

alonecia

Table No. 5 shows the arsenic and lead in each patient from whom a specimen was taken. It will be noted that there is practically little difference between the males and females in this group. The ratio of males to females having alopecia is about three to one in this particular instance. An unusually close value is found for the percentages of arsenic and lead in each of these groups. Our tabulation has not included the classification in this group by decades. In some instances the table indicates that a patient showing no arsenic rarely shows no lead, and vice versa

In the succeeding year an additional group of

arsenic in the case of males and 72% in the case of females.

In going over the entire group of patients, almost 800 in number, it is quite apparent that variations of seasonal nature are indicated in each group. The most minutely studied group of patients is found in tables No. 5 and No. 6.

DISCUSSION

The discussion and the results of the study of alopecia areata in its various forms, have indicated that our investigations add additional factors which are associated with the so-called toxic theory. The data presented indicate that the effect of common metals on the reticulo endo-

patients were collected, as indicated in table No. 6. This table again shows the presence of arsenic and lead in the specimens of urine taken from males and females of this group. Here, however, the percentages having arsenic and lead are very much the same, the percentages being unusually high; e. g., in the case of males 80.9% show arsenic and 91% show lead. In the case of the females 94.1% show arsenic and 88.2% show lead.

Proceeding to a more recent group, taken during the past year, it is indicated that 80% show

thelial system plays a very distinct part in the production of this clinical symptom. Examinations of the hair, blood, urine, and the alopecia areas have been made, and it is our belief that definite evidence is offered in connection with these examinations. The analogy of the action of thallium in epilation closely simulates symptoms observed in alopecia areata, and through this suggestion our attention was directed to the estimation of arsenic and lead. The wide-spread prevalence of these two elements in foods, drugs, and liquids, due to contamination and spray resi-

dues, easily accounts for their presence in the body, fluids, and tissues. Furthermore, it has been shown that metals definitely disturb the basal metabolic rate, and also the blood count on these alopecia cases, indicated by a relative lymphocytosis. Histopathological and microchemical examinations are earried out on specimens obtained from the various groups of individuals.

The treatment of alopecia areata has consisted

in cheeking the patients for focal infections, and the administration of freshly prepared sodium thiosulphate. Sterile crystals are readily available for this purpose. Only the purest material should be used. The treatment consisted in the use of doses of 1.0 and 3.0 grams three times each week. Diseased teeth, tonsils, sinuses, or other toxic possibilities should always be eliminated previous to the treatment.

The authors believe that these investigations offer additional confirmation of the so-called toxic theory. The use of spray residues, and lead pipe for conducting purposes should be avoided for the reason that they offer adequate sources for contamination. The investigations on these patients have shown definitely that with the proper treatment the majority of the individuals have their hair restored. The use of sodium thiosulphate in the form of pure crystals (Sulfactol) has promoted the increase in the elimination of the metals. Any patients with a lowered basal metabolism had glandular therapy added to their treatment. In the entire series of patients only three have failed to respond.

WHAT THE ORTHOPEDIST CAN DO FOR THE ARTHRITIC

By JOHN P. STUMP, M.D., NEW YORK, N. Y.

From the Arthritis Department, New York Post Graduate Hospital

In this talk I intend to call to your attention the various orthepedic considerations which are important in the treatment of arthritis. I hope when I have finished that I will have left with you firmly fixed in your minds the all-important problem of the prevention of deformities.

I. EARLY STAGE WITHOUT DEFORMITY GENERAL CONSIDERATIONS

- (1) Painful joints should be put to rest in the position of election, or in a position to prevent deformities. When the knee is involved, avoid flexion of the knee and the accompanying abduction and external rotation of the hip. If ankylosis is impending, get the joint into the position of election—for example, in an elbow put it in the position best suited for the individual. An inactive woman would be most benefited with her elbow at 70 degrees flexion; she could arrange her hair, feed herself and perform similar personal actions. A doctor would want a relatively straight elbow, probably 30 degrees flexion.
- (2) When joints are swollen, tense, and painful, withdrawal of the fluid should be employed and the injection of air into the joint affords a cushion upon which the patient can walk. Air is injected at 30 mm. pressure.
- (3) In pyogenic infections the suppurating joints should be drained, washed out and protected by immobilization.

DEFORMITIES

Deformities are caused by painful and spastic muscles demanding relaxation and aided by gravity. In the early stages our orthopedic problem is concerned with the prevention of deformities. This problem is best approached by first considering what are:

The Common Deformities.

Feet—Equino-valgus.

Knee—Flexion with abduction and external rotation of the hip.

Hip—Adduction and Flexion.

Fingers—Flexion—claw hand.

Wrist-Flexion.

Elbow-Flexion 30°-45° with pronation.

Shoulder—Adduction.

Jaw-Fixed closed.

Spine—Flexion generally with rotation.

BED PATIENTS

The doctor and nurse must be taught to recognize beginning deformity; and when patients are in bed, it is most important that they be on the alert for the earliest signs of deformity and pre-

vent this unfortunate complication. The bed should have a firm mattress which will not allow the body to sink into a bad position, as for example to allow the back to go into a position of flexion for hours at a time. The weight of the bed clothes should be kept off the painful joints. Frequently the pressure of the bed clothes will cause a foot drop. A cradle should be used; and if necessary a posterior molded splint can be employed to hold the foot in the physiological position. In the same manner a molded splint or cast can be employed to prevent flexion of the knee; a spica for the hip; and a spica or abduction splint for the shoulder. Remember to teach your interns and nurses to spot deformities at their inception.

AMBULATORY CASES

The first consideration in the prevention of deformities in ambulatory cases is posture. When you make a diagnosis of arthritis or you fear the onset of the arthritic state, immediately give thought to your patient's posture. Deformities are insidious in onset and their progress slow; and if you relent in your watchfulness for the shortest period, you are apt to find yourself confronted with a serious deformity which might

have been prevented.

The primary consideration in posture is that in the lower extremities. The legs and feet are so constructed that the weight bearing line is a straight line from the anterior superior spine of the ilium, through the center of the patella, along the tibial ridge, and passing out of the foot through the second toe. The weight should be carried on the front of the foot, the terminal ends of the first and fifth metatarsals being used for weight bearing, and the os calcis being used only to steady or balance in walking and standing. In order to preserve this correct weight bearing attitude it is necessary to instruct your ambulatory cases to walk with the weight on the front of their feet and not to jolt down on their heels each time they put their feet on the ground. The position of moderate valgus in which most people walk should be corrected so that the imaginary line described above falls as it should through the second toe. This correct posture, accompanied by exercises and proper shoes, may be sufficient to overcome deformity in the feet; if not, it is necessary to use a malleable metal plate in the shoe which is not a true support but in fact a guide which causes the foot to take its proper position.

It has been my observation that physicians will seek the aid of orthopedists and skilled brace makers when their patients need some support such as a spinal brace or walking caliper; but when they are suffering from so-called "flat foot." the doctor very lightly suggests that the patient get arch built shoes or Dr. Scholl's arch supports. It is not possible to get the proper education of the feet with shoes alone; exercises are essential and inserts in the shoes are imperative in more than 80 per cent of patients suffering from foot strain. The inserts should be made of metal strong enough to withstand the patient's weight, and malleable enough to be repeatedly adjusted to the progressive changes in the foot as improvement is gradually obtained. The metal insert should have the definite form and size of the patient's foot, and this can be obtained only by building it over an exact model of the foot.

If the true importance of the feet in the treatment of arthritis is to be obtained the term "flat foot" must be abandoned, and weak feet used in its stead. Weak feet are feet which are rotated out of the weight-bearing line, hence causing unnecessary muscle strain which promotes fatigue, and in an arthritic further depletes an already weakened constitution. Furthermore, muscle strain actually weakens the resistance of the bony supports and causes improper points of weight-bearing in the joints, thus producing in the lower extremities, pelvis, and spine a most fertile field in which arthritis may flourish.

In the knees deformity is prevented by physiotherapy, which promotes motion and increases circulation. By physiotherapy I mean primarily diathermy and massage. In extreme cases braces will be needed to prevent flexion deformity.

Deformity in the hip in ambulatory patients immediately calls for consideration of the foundation as described when considering the feet. One thing always to be remembered is that deformity of the hip, that is flexion and adduction, causes a tilting of the pelvis, which in turn promotes curvature and rotation of the spine, putting strain on that structure and decreasing its resistance to arthritis. The prevention of hip deformity is obtained by physiotherapy and, when necessary, braces. Deformity in the shoulders, elbows, wrists, and fingers is prevented by physiotherapy and by braces. If fixation of the joints cannot be prevented, then employ casts and braces to hold the joints in the positions of optimum flexion for the patient.

Prevention of deformity in the spine should be one of our first considerations, because once a patient has a fixed, flexed, and rotated spine, medicine and surgery are helpless. Watch for the early flexions and fixations of the spine, prevent them by employing a support such as a Taylor spinal brace, and in selected cases use bony fixation.

One consideration frequently lost sight of is that children and sick adults spend many of their hours asleep when they are off guard, and this affords an excellent opportunity for the development of deformity. This danger is overcome by the employment of night braces.

II. LATE STAGE WITH DEFORMITY

Now we must consider what surgery can offer a person who has had the misfortune to allow fixed deformity to occur. In the equino-valgus deformity of the feet an effort should be made to manipulate the feet under anesthesia, and hold them in position in casts. If this fails or is impractical a cuneiform osteotomy, followed by casts, should be performed. When there is fixed bony deformity of the knees, hips, shoulders, or elbows, the treatment indicated is an osteotomy or arthroplasty. The fingers should be fixed in position best suited for the patient. In the wrist bony fixation is treated by an osteotomy because an arthroplasty is difficult and the results are not satisfactory.

Surgery offers absolutely no aid to a fixed, bony deformity of the spine and that is the first reason why every effort should be made to prevent spinal deformity. If any fixation is fibrous and not true bony ankylosis, the deformity might be overcome by manipulation under anesthesia; but if this is attempted it must be remembered that the bones have probably suffered severe atrophy of disuse, and that manipulation under anesthesia is likely to cause fracture or destruction of the bones.

In some cases of atrophic arthritis of the knee the synovial membrane may be the focus of infection; and a pansynovectomy removes the cause and provides a cure.

Spurs, joint mice, damaged synovia and cartilages may be removed, but in all operative procedures it must be remembered that in treating arthrities we are dealing with people who are constitutionally weakened and are not good operative risks.

Let me impress upon you the necessity of adopting the same attitude in treating orthopedic patients as the physician who treats pulmonary tuberculosis. Don't expect to cure your orthopedic patients in days or weeks—be prepared to wait months and years for results.

SUMMARY

We have considered that, from the orthopedic view, in the acute stage of arthritis rest is the important treatment; that the treatment of severe deformities offers only limited benefit; and finally that the important and first object of the treatment of arthritis is to remember the typical deformities and he on the alert to prevent them,

SULFARSPHENAMINE IN VINCENT'S ANGINA

By H. J. HARRIS, M.D., WESTPORT, N. Y.

OUR HUNDRED cases of Vincent's Angina in Essex County, N. Y., occurring during the year 1931, were reported by me in the New YORK STATE JOURNAL OF MEDICINE OF February 1, 1932, treated with one of the arsphenamines given in three doses, a week apart. While that surprisingly large incidence of Vincent's angina in Essex County, N. Y., has rapidly decreased, there still occurs in this region many sporadic cases of a less severe and less infectious, but yet stubborn, nature. As these often fail to respond to local measures such as potassium chlorate, sodium perborate and their flavored proprietary preparations, and since the disease may be so serious in some of its manifestations, I have continued to use the intravenous sulfarsphenamine mentioned in my original communications, realizing full well the possible reactions that might occur.

Peculiarly, in about five hundred injections of sulfarsphenamine, of various brands, given to patients with Vincent's angina, during the epidemic in question, no noticeable reactions occured except for an occasional patient who was actively nauseated or vomited during or immediately after the injection. Since reporting this series I have had five experiences which forcefully brought the question of toxi-

city and reactions to my attention.

The cases listed below are especially impressive since they occurred within a few months, with the same technic and with various brands of sulfarsphenamine:

Case 1-A young married woman with ulceration of gums and lips, getting steadily worse under local treatment, was given 0.3 gm. of sulfarsphenamine but failed to improve within the usual forty-eight-hour period. Five days later she was given a second dose of 0.3 gm. which was followed not only by prompt healing of all lesions but also by a mild arsenical rash on the ventral surface of both wrists, around the nipples and the labia minora. One intravenous dose of 15 grains of sodium thiosulphate (sulfactol) in 10 c.c. of distilled water was given intravenously and the rash disappeared. The usual third dose of sulfarsphenamine was omitted.

Case 2—A young vigorous man of 23, with ulceration of gums and tonsils due to Vincent's angina, not improving under local therapy, was sent to me for sulfarsphenamine. He improved markedly after the first dose of sulfarsphenamine (0.4 gms.). A second dose was given a week later, all lesions healing rapidly. A mild arseni-cal rash of the wrists developed and disappeared spon-

taneously.

Case 3-A boy of 12 consulted me complaining of a mild sore throat, obviously Vincent's angina of the tonsils, and was given 0.3 gm. sulfarsphenamine intravenously with no apparent improvement. Five days later a second dose of 0.3 gm. was given intramuscularly. This was followed in two days by a rapidly developing, very heavy, measles-like arsenical rash covering his entire body, apparently of the exfoliative type. Sod. thiosulfate by mouth and by vein daily was followed by improvement in 24 hours and complete disappearance of the rash in 4 days, with no ill effects. No exfoliation

Case 4—A man of 42 had tried numerous local methods of treatment of a mild but long persistent Vincent's of the gums and hard palate and was finally given 0.3 gm. of sulfarsphenamine intravenuosly. Within an hour he was vomiting freely and having copious watery diarrhea which was attended by shock and ultimate collapse within four hours. Improvement began soon after an intravenous dose of 15 grains of sodium thiosulphate (sulfactol) although death had seemed too imminent for any treatment to be effective. Undoubtedly this should have been given carlier. He recovered completely in three days.

Case 5-I myself was the fifth patient. Having developed an often-recurring patch of obvious Vincent's of the gum which only partly healed with local drugs, quartz light, etc., flaring up at intervals, I was given 0.3 gm. of sulfarsphenamine intravenously and felt no ill effects. Since I was well within two days, further treatment was neglected. Perhaps six months later, a similar patch recurred and a second dose was given me. This precipitated an immediate nitritoid crisis with flushing of the skin, nausea and generalized urticaria which was promptly relieved by adrenalin. The patch of Vincent's disappeared within two or three days. About four months later, because of a similar patch, all manner of local therapy was tried without avail before deciding to risk another reaction. A similar reaction again occurred within thirty seconds after this dose was administered and was relieved rather tardily by intramuscular ephe-

Comment: I cannot enter into controversy as to the relative safety of sulfarsphenamine as compared with the other arsphenamines. I can state, however, that reactions can occur with greater frequency than would ordinarily be anticipated and that they may be negligible or fatal. One may be lulled into a false sense of security by previous freedom from ill effects. Obviously, i' is unsafe to use this drug unless one is prepare to administer sodium thiosulphate intravenousl promptly at the first sign of severe reaction or advancing arsenical dermatitis.

With proper precautions, sulfarsphenamine can be used with reasonable safety in intractable cases of Vincent's angina, as in syphilis. It is essential to keep the patient under observation for at least fifteen minutes after the injection; to give sodium thiosulphate promptly when indicated; and to be prepared for late reactions, such as dermatitis, which are successfully treatable if seen promptly. There seems no reason to abandon the use of so specific a drug.

MEDICAL INSURANCE IN CUBA

There are three principal systems for delivering medical service to the people:

- 1. Private practice.
- State Medicine.
- 3. Insurance by Voluntary Groups.

The people of the United States are so accustomed to the system of private practice that they are scarcely aware that millions of people in England and Germany are recipients of medical treatment administered by the State; while other countries have experimented with sickness insurance given by voluntary groups conducted by the same commercial methods that are used in insurance against accidents and fire,

The Island of Cuba offers an extensive examplc of sickness insurance, for approximately onehalf of its medical service is given by means of insurance groups organized for the purpose of giving treatment to their sick members. An excellent description of the Cuban system is contained in a four-page article in the American Association Bulletin of June, 1933, by Dr. R. G.

Leland, Director of the Bureau of Economics of the American Medical Association.

Cuba has an area of about 45,000 square miles, and a population of about 3,500,000, of whom about 500,000 live in the metropolitan area of Habana. There are about 3,000 practising physicians in Cuba, or about one to every 1,200 people. One may visualize Cuban conditions by comparing them with those of New Jersey. While New Jersey has only one-fifth of the area of Cuba, it has about the same population, the same number of physicians, and the same grouping of a large part of its population in a metropolitan area.

Dr. Leland brings out four striking points in connection with the group-insurance service:

1. Origin and Development: The insurance system was organized in the decade of the seventies, when the Spaniards introduced the paternalistic system of giving medical care to the workmen on their great plantations which sprang up with modern industrial conditions. Health and happiness of the workmen were essential to financial prosperity; and so the plantation owners provided not only medical service, but theaters and art instruction suited to the peculiar needs of the workmen. Private provision for these services grew naturally into the formation of insurance societies which gave both medical service and entertainment for a membership fee of two dollars a month. This fee produced enough income to build and support hospitals and run the An elaborate system of super salesmanship kept the membership filled and left but few people who paid fees. The salaries paid to the society physicians were ridiculously small, and were below living wages; and yet the doctor could not secure private cases for they could not compete with the salesmen of the societies.

2. Universality of the Service: A commendable spirit of social service was shown by both the physicians and the societies toward those who could not pay the insurance dues. If a non-member was taken sick, he was put upon the membership list and given free treatments, even though he immediately dropped his membership when he recovered. The insurance organizations capitalized the value of a good reputation for

giving service.

3. Abuse of the System: The insurance system was used by all classes of people. The plantation owners and superintendents paid the same

fees as the poor members, and used the facilities of the hospitals and other forms of medical service without paying a fee except their membership dues. This is the most pernicious element in the insurance system, for it leaves few pay patients for the independent doctors. It is estimated that one quarter of the members of the insurance societies are abundantly able to pay ordinary medical fees to private physicians. Everybody is in the societies, but there is a great inequality in the service that is given, the upper classes of course receiving the best.

4. Organization of Physicians: The physicians of Cuba have not been organized except through the insurance societies. There has been no such thing as a medical society of the nation, or the district, or the county, until recent years. The Medical Federation of Cuba was organized in 1925, and has formed district branches. It has been active in promoting reforms which will make practice like that in the United States. Among the changes which its members have advocated are the following:

1. Making the minimum full time salary of an insurance doctor \$1,200 a year, a living wage.

2. The elevation of standards of practice, espe-

cially in the hospitals.

3. The requirement that the insurance doctors should give an average of fifteen minutes to each patient, instead of treating forty per hour, which has been the usual average.

4. The elimination of unnecessary calls, for the members make inordinate demands on the doctors.

5. A change in the methods of employing and paying the salesmen of the insurance companies.

Progress: The Federation has conducted a campaign of education among both the people and the doctors, and is making considerable progress in securing the cooperation of the physicians of the insurance societies. There are, for example, thirty-four medical insurance societies in Habana, of which twenty-one are Cuban, and friendly to the Federation; twelve are Spanish, five being cooperative and seven unfriendly; and one is Chinese and friendly.

Political considerations may hinder the adoption of the progressive reforms, for candidates use the societies for their own ends. Yet there are bright prospects that the National Medical Society will be able to accomplish much in the

next five years.

MEDICAL PROGRESS

Pneumothorax Treatment in Dry Pleurisy. -Eberhard Regenbogen states that by making use of pneumothorax in dry pleurisy it is possible both to control the pain and apparently to prevent formation of adhesions. On a basis of 6 case histories he demonstrates that the introduction of gas produces such a complete separation of the diseased leaves of the pleura that the pain ceases and its return is made almost impos-No other measure so quickly and comsible. To produce an pletely accomplishes this end. equivalent result it would be necessary to have recourse to strong anodyne remedies of the morphine group, from the use of which for many reasons it is better to refrain. Pneumothorax has the advantage over these and similar measures that the effect of a single inflation lasts a long time, and commonly results in a complete cure of the pleuritie process. Unlike certain authors who use 600-1000 c.e. at the first inflation for pleurisy, Regenbogen uses only 300-500 e.e. It is his experience that when 300 e.e. have been reached the pains already disappear. When so small an amount as 300 e.e. has been introduced, fluoroscopy fails to reveal the slight separation of the lung from the thoracie wall; it requires a good roentgenogram to reveal satisfactorily the degree and site of the inflation. The use of a relatively small amount of gas has the advantage of redueing to a minimum the mechanical irritation caused by the gas, which in the opinion of many authors, is at least in part responsible for the formation of an exudate. It is debatable, however, whether the appearance of the exudate is really due to the pneumothorax, or to the natural transformation of a dry pleurisy into an exudative one. In any event, the formation of such an exudate is searcely to be feared when small amounts of gas are employed. In Regenbogen's opinion, the introduction of air with the resultant cessation of the frietion of the inflamed leaves of the pleura serves rather to prevent the formation of such an exudate and by placing the pleura at rest considerably shortens the duration of the illness .--Deutsche medizinische Wochenschrift, June 2, 1933.

A Method for Obtaining Blood Pressure by Arterial Compression and Simultaneous Capillary Observation.—J. Q. Griffith, Jr., and Leon H. Collins, Jr., describe a method for obtaining blood pressure in the brachial artery by brachial compression with a blood pressure cuff and simultaneous observation of the blood flow in the digital capillaries of the nail bed. As the method does not require pulsation, it is especially valuable in cases in which this is not perceptible. For

observation of the nail bed a microscope lamp with a 500-watt bulb is set up so that its rays fall on the stage of a microscope at an angle of 45°. A spherical liter-flask filled with distilled water is interposed between the lamp and the stage. On the side of the microscope opposite the lamp pillows are placed to support the patient's arm. One of the patient's fingers, usually the fourth, is placed in a small trough-shaped wooden box and gently supported on the sides by plasticine and then placed directly on the stage. A drop of immersion oil is then applied to the selected finger just back of the nail. To take the reading, the blood pressure euff is quickly pumped up to a point above the systolic pressure and clamped while the capillaries are watched. flow will continue for about a minute, and then eertain of the capillaries will appear to be filled with stagnant granules. If the flow does not stop, it means that a point above systolic pressure has not been reached. There may be slight to and fro movements of the granules, but no definite The pressure in the cuff is now slowly lowered, and the point where the flow first definitely returns is read on the manometer. This is taken as the systolic pressure, or in a case without pulsation, as mean pressure. The results obtained by this procedure were compared with those of ansculation in normal persons and varied between five and twelve millimeters lower than that obtained immediately afterward by auscultation. A patient without pulsation in the brachial arteries was studied and the capillary reading was confirmed by a direct pressure reading after arterial puneture. This indicates that the results obtained by the capillary reading are fairly accurate.-The American Heart Journal, June, 1933, viii, 5.

The Sphygmomanometer in the Diagnosis of Cardiac Irregularities.-Maurice E. Shaw, writing in the British Medical Journal, June 3, 1933, i, 3778, draws attention to a method which has proved of value to him in the routine investigation of blood pressure in patients with car-diac irregularities. The fact that pulsus alternans may often be recognized while one is taking the blood pressure deserves to be more widely appreciated by medical men. Other factors remaining constant, the maximum arterial pressure achieved by any beat will depend upon the strength of the ventricular contraction. Where such contractions alternate in strength there will be alternation of maximum (systolie) pressure. This, as a rule, is quite easily recognized with the manometer. A variation of 5 mm. of mercury can be recognized with ease, and smaller variations might be distinguished if the possibility of alternation were borne in mind when the blood pressure was being taken. If alternate beats reach a different systolic pressure the audible number of beats will be halved as soon as the pressure in the cuff exceeds the lower of the two maximum pressures. It must be remembered that alternate strong and weak beats may be due to extrasystoles alternating with normal beats. In such cases there will be a disturbance of rhythm which will not, as a rule, be difficult to recognize, though the halving of the pulse rate will be observed as soon as the pressure in the cuff of the sphygmomanometer is sufficient to obliterate the beats due to the extrasystoles. In auricular fibrillation it is impossible to estimate the systolic blood pressure in the ordinary way; the first beat that is heard on deflating the cuff is usually an isolated one, and it may be necessary to reduce the pressure in the cuff by 20 or 30 mm. before the number of beats heard bears any relation to the charted pulse rate. If the cuff is held inflated at the pressure at which the first beat is heard only two or three beats a minute may be heard. As the cuff is slowly deflated the number gradually increases, and it is possible to get some idea of the variations in systolic pressure between the largest and smallest beats. The complete disorganization of ventricular rhythm is suggested by the fact that the sound of each beat varies, even though the pressure in the cuff is constant. Ectopic beats of ventricular origin do not, as a rule, disturb the dominant rhythm of the heart. These beats can be excluded by raising the pressure in the cuff to a point just below the pressure generated by the normal beats. Where the ectopic beats are of auricular origin there is usually interference with the dominant rhythm, and the distinction is less easy if the abnormal beats are very frequent, but in many cases the extrasystoles seem to generate a fairly constant pressure. If careful attention is paid both to the rhythm and to the actual pressures of abnormal beats valuable information may be obtained without employing elaborate appa-

An Appraisal of the Value of Vaccine Therapy in Chronic Arthritis.—In an attempt to obtain a cross-section of opinion in regard to the value of vaccines in chronic arthritis, Sydney R. Miller sent a questionnaire to a number of internists in the leading medical centers of the country and to a group of preeminent immunologists and bacteriologists. An analysis of the replies shows that approximately two-thirds concur in the opinion that vaccines are of value when used at the proper time and in the\proper manner, whatever that may be. Autogenous vaccines are preferable in the majority of patients. In a minority stock vaccines are equally good. Just what the specific indications are for the use of vac-

cines, their dosage, their method of administration, etc., must still be left as open questions. At the moment it would appear that vaccine therapy in chronic arthritis is appropriately limited to the atrophic form, and has little, if any, application in the hypertrophic type. The consensus of opinion inclines to the view that the mechanism whereby improvement occurs under vaccine treatment is in some way related to a desensitization process rather than to the formation of specific antibodies. In harmony with such a concept, small doses of vaccine are most advocated, given preferably intravenously, and continued over a long period of time, avoiding pronounced constitutional reactions. It would seem apparent that, in the light of more recent bacteriological studies, greater attention should be paid to the process of vaccine preparation, chiefly in terms of attempting to secure virulent strains of the autogenous Recent imdisease-provoking organisms. munological studies lead to the conclusion that a vaccine, to be of probable value, should contain the whole bacterial antigen. All call attention to the fact that the nucleoprotein and carbohydrate fractions which constitute the whole bacterial antigen are bound together in a very loose way and are easily broken up by solution, by autolysis, and in some instances by heat sterilization. With these and other considerations in mind, several voice the belief that we do not yet know the best method of preparing vaccines. It is probably essential that the organism in question be shown or known to be an antigenically potent strain and that antigenic dissociation must be The whole status of vaccines and avoided. their therapeutic use in arthritis is in a most unsettled and empirical state.-Southern Medical Journal, July, 1933, xxvi, 7.

The So-Called Acute Febrile Perniciosiform Anemias.—On the basis of a personal case studied accurately over a long period, D. Campanacci says that Italy also has cases resembling those recently described by American authors (Brill, Lederer) under the name of "acute hemolytic anemia" and "acute febrile anemia," with acute febrile onset, moderate hepato-splenomegaly, oligocythemia and oligochromemia, hemoglobin index in excess of 1, normoblasts, megaloblasts and occasional myelocytes in the circulation, urobilinuria and bilirubinemia with indirect diazo-reaction, running a rapid and benign course. He would, however, partly modify the American conclusions by affirming that such forms of anemia may present, as did his own case, achylia and polynuclear leucopenia, so that what have been regarded as fundamental criteria for differentiating acute hemolytic anemia from Biermer's pernicious anemia become, instead, imThe absence of microcytosis and of modifications in the globular resistance, together with the merely moderate character of the splenomegaly made it appear that the hemolysis in these acute cases should not be regarded as of splenic origin. These findings, taken in eonnection with the presence of signs of myelopathic involvement (megaloblasts, myelocytes) constitute one more argument for considering such cases forms of the classical Biermer's anemia, of which they scemingly represent one clinical variety. Notwithstanding the obscure ctiology of these forms of anemia, Campanacci believes that their genesis must rest on the threefold foundation of organic soil, achylia, and acute toxinfection. This last component, indeed would seem rather to be capable of upsetting an equilibrium already unstable than of creating ex novo an entire disease picture, while on the basis of the criterion ex adjuvantibus the achylia would always be expected to play a fundamental role. Such a criterion even confirms the close relation of these forms to Biermer's anemia, since it is well known that in the latter the results of early hematological examinations in certain cases point to the primary existence of a disequilibrium of hematopoiesis and also of achylia, upon which were superimposed at a later time signs of morbid hyperhemolyses. In the author's case the only variations from those forms which in their clinical physiognomy meet the test for Biermer's anemia were the irregular high fever with chills, of septicemic type, with which the case began, and the spontaneous remission of the disease. In view of these considerations it seems that the affection should not be considered a new entity, but rather a elinical variety of pernicious anemia.-Riforma medica, May 20, 1933. Protection of the Peritoneum Against Infection.-Bernhard Steinberg and Harry Goldblatt describe experiments on dogs which formed the basis of the method which they have applied clinically. Briefly, dogs were injected intraperitoneally with 50 c.c. of a 1 per cent, solution of gum tragacanth in physio-

portant sigus for bringing these two forms together under a single nosological heading,

at least from the hematological point of view.

Protection of the Pertoneum Against Infection.—Bernhard Steinberg and Harry Gold-blatt describe experiments on dogs which formed the basis of the method which they have applied clinically. Briefly, dogs were injected intraperitoneally with 50 c.c. of a 1 per cent. solution of gum tragacanth in physiological saline in which were suspended 200,-000,000 killed Bacilli coli per cubic centimeter. At varying intervals thereafter the animals were infected by injections of living B. coli and other microorganisms in a suspension of 2.5 per cent. gum tragacanth. Hourly white cell counts of the peritoneal exudate were then made. It was found that in dogs a single intraperitoneal injection was effective in twelve hours against infection with B. coli and other intestinal microorganisms. Control

animals which were infected, but did not receive the protective injection, succumbed. The procedure was applied clinically in 100 patients. From twelve to forty-eight hours prior to surgical operation, they were given an intraperitoneal injection of 30 c.c. of a suspension of B. coli (200,000,000 per cubic centimeter) in 1 per cent. gum tragacanth in physiological saline. The injection was made in the midline, a little below the umbilicus, with a No. 15 gauge needle, 2 inches long. One-half hour before the injection 1/6 to 1/4 of a grain of morphine sulphate was administered and repeated at four hour intervals for sixteen hours, as the reactions are those of peritoneal irritation and can be controlled with morphine. The method was employed in cases in which there was danger of peritoneal soiling, as in intesti-nal resection, "interval" appendectomy, and chronic pelvic conditions with adhesions requiring removal of pelvic organs. A definite contraindication to the use of this method is the presence of general peritonitis. None of the patients receiving the injection developed peritonitis. The factor responsible for the protection against infection is apparently predominantly polymorphonuclear leucocytes, since the protective substance in the peritoneal cavity evokes the exudation of a large number of polymorphonuclears which are available for phagocytic action at the time of infection. The protection must be regarded as nonspecifie since the protective material was effective not only against B. coli, but also against B. pyocyaneus, Streptococcus facalis, B. welchii, and other organisms found in the feces.—Surgery. Gynecology and Obstetrics, July, 1933, lvii, 1.

Two Cases of Bacillus Alcaligenes Infection. -W. K. Anderson says that Bacillus facalis alcaligenes infection is sufficiently uncommon to justify the record of two cases of it. This bacillus usually occurs in the intestinal tract and is regarded frequently as a saprophyte. An inflammatory condition of the intestines appears to favor the growth of the organism The cases here reported occurred in men 25 and 20 years of age. From the history and clinical appearances these two cases would have passed for rheumatic fever. patients both had cardiac valvular and myocardial lesions with painful and swollen joints. As the symptoms did not respond to the salicylates, some other form of infection was sought after and the Bacillus facalis alcaligenes was found. In both cases treatment with mercurochrome resulted in improvement. A tablespoonful of 1 per cent mercurochrome in water was administered once daily in the first case and twice daily in the second. The author brings up the question as to whether the cardiac lesions with recurrent rheumatism were

the direct result of the Bacillus alcaligenes infection supplied from the gut over a long period of time, or whether these severe attacks described were new infections in previously rheumatic subjects.—Practitioner, July. 1933, exxxi, 871.

Congestive Heart Failure and Angina Pectoris.—Herrman L. Blumgart, Samuel Levine, and David D. Berlin present a report on the favorable effect of thyroidectomy in three cases of congestive heart failure and one of angina pectoris, in which there was no clinical or pathological evidence of thyroid toxicity. They were led to try this measure because of the favorable effects of a reduction in the metabolic rate seen in certain thyrotoxic patients with congestive heart failure whose circulation becomes compensated after subtotal thyroidectomy. The hearts of such patients are evidently equal to the demands of a normal metabolic rate, though not to the demands of the elevated metabolic rate of thyrotoxicosis. This suggested the possibility that persons with normal metabolism who suffer from congestive heart failure might show striking improvement if the metabolic rate were significantly lowered. In the patients studied the signs and symptoms of circulatory insufficiency and of angina pectoris had persisted for a considerable time in spite of all known medical procedures. In two of the three patients with severe congestive heart failure tubtotal thyroidectomy caused a fall in the metabolic rate which reached its maximum about three weeks after the operation. Clinical improvement paralleled the lowered metabolism and was evidenced by the disappearance of edema, the increased vital capacity of the lungs and the ability to be up and about the ward without discomfort. During the next two weeks, the metabolic rates in these two patients again rose toward the preoperative normal level, and their clinical condition became less favorable. The patient with angina pectoris had shown no recurrence of the attacks of angina pectoris since subtotal thyroidectomy, although he had returned to work and active life. In one patient with congestive heart failure complete ablation of all thyroid tissue was done, the parathyroid glands being spared. This patient has maintained his conspicuous clinical improvement and the metabolic rate has remained persistently lowered for more than six weeks. Further studies are being made in order to appraise the value of thyroidectomy roentgen irradiation. The authors suggest that at the present time the procedure should be employed only in cases in which all known therapeutic measures have proved ineffectual.—Archives of Internal Medicine, June, 1933, li, 6.

Recurrent or Intermittent Jaundice in Youth.—After reviewing the main points in the differential diagnosis of hemolytic jaundice and hypertrophic biliary cirrhosis, Willis E. Hartshorn describes an atypical case of biliary cirrhosis. The patient, a girl a little over 8 years of age, had a first attack of jaundice which lasted about ten days and then cleared up. There was a second attack a year later, and a third attack when the patient was 11 years of age. After the jaundice had persisted for three months she was admitted to the hospital. The laboratory findings at this time were as follows: Red blood cells, 4,410,000; hemoglobin, 90 per cent; white cells, 11,350; polymorphonuclear leucocytes, 51 per cent. The icterus index was 50, whereas, normally, it should be from 4 to 6. The analysis of the case suggested more a jaundice due to obstruction than a familial, cirrhotic or hemolytic jaundice. After the patient had been in the hospital for a month with little improvement, an exploratory laparotomy was advised. This was refused and the child was taken to her home. She died two years later from septicemia due to a throat infection, having been constantly jaundiced during this period. At autopsy the spleen was found enlarged about six times. The liver presented a condition in which both hypertrophic and atrophic cirrhosis were found, but not Hanot's This disease is characterized by chronic jaundice and marked enlargement of the liver and spleen in the absence of ascites. From time to time exacerbations occur, with fever, pain over the liver and spleen and increased jaundice. In the case described there was very moderate enlargement of the liver with no ascites until it appeared as a complication of the secondary septicemia, when the spleen, not markedly enlarged before, rapidly increased in size. There was no fever at any time; neither was there an increase in the number of reticulocytes or fragility of the red cells, such as is found in chronic hemolytic The laboratory findings did not iaundice. point to a medical solution of the problem and, therefore, to save the life of the child, surgical intervention would have been justified. In persistent cases of jaundice before the age of twenty the blood picture must be thoroughly investigated before suggesting surgical interference. In hemolytic jaundice with large splenic tumor, splenectomy is indicated. In the case here described it would have been of doubtful value. If jaundice continues over a period of years without relief, liver necrosis and death are sure. Exploratory operation is therefore indicated in atypical cases of the nature above described. - New England Journal of . Medicine, June 22, 1933, ccviii, 25.

LEGAL

CRIMINAL LAW-STATUTE PROVIDING FOR ALTERNATE JURORS

By LORENZ J BROSNAN, ESQ.

Counsel Medical Society of the State of New York

From time to time public attention is directed to the waste of time and money in the trial of criminal cases. These trials are very often protracted and at times instrials have resulted through illness, death or insunity of one of the jurors. It should be borne in mind that where a juror becomes incapacitated or dies, it is mandatory upon the trial judge to declare a mistrial which, of course means that the case must be retried from its beginning.

For some years those interested in the proper administration of our law have suggested a simple way to remedy this situation, viz, by legislation providing for an alternate juror who should be sworn as any other juror, hear all the evidence and thus be prepared to take the place of any regular juror who became incapacitated or died

during the trial of the case

An extremely desirable piece of legislation was passed by the legislature at its recent session and became a law with the approval of Governor Lehman the purpose of which is to prevent as far as possible unnecessary retrials. The law referred to adds a new section to our Code of Criminal Procedure providing for alternate juriors in felony trials. The new section reads as follows.

'Sec. 358 a Alternate jurors, know chosen, rights and duties of alternate jurors. Whenever, in the opinion of a judge of a court of criminal jurisdiction about to try with a jury a defendant against whom has been filed any indictinent or information for a felony the trial is likely to be a protracted one the court may cause an entry to that effect to be made in the munites of the court and thereupon immediately after the jury is impaneled and sworn the court may direct the calling of one or two additional jurors in its direction, to be known as alternate jurors'. Such jurors must be drawn from the same source, and in the same manner, and have the same qualifications as the jurors already sworn and be subject to the same examination and challenges. Such alternate jurors shall be seated with the jurors, with equal power and facilities for seeing and hearing the proceedings in the case and shall take the same outh as the jurors already selected, and must attend at all times upon the trial of the cause in company with the other jurors, and for a failure so to do ore holde to be punished for contempt. They shall obey the orders of and be bound by the admonition of the court upon each adjournment of the court, and if the regular jurors are ordered to be kept in the custody of the sheriff during the trial of the cause, such alternate jurors, and except, in confinement with the other jurors, and except, in confinement with the other jurors, and except heps in confinement with the other jurors, and except heps in confinement with the other jurors all also be kept in confinement with the other jurors are ordered to be kept in the custody of the sheriff during the trial of the cause, such alternate jurors shall also be kept in confinement with the other jurors, and except, or part of the cause to the jury. If before the final submission of the case to the jury if before the final submission of the case to the jury or become the final submission of the case to the jury if before the name of an afternate, who shall then tak

discharged juror in the jury box, and be subject to the same rules and regulations as though he had been selected as one of the original jurors.

List year an almost identical section was adopted by Congress and is at present in operation in our Federal Courts. It has already demon strated its usefulness. At the time of this writing a protracted criminal trial is in progress before a Federal Judge that has been under way for several months. In that case one of the jurors died, and his place was taken by an alternate, thereby accomplishing a great saving of time and expense

In connection with this statutory modification of the jury system that is being put into effect it is appropriate to consider some of the features of the jury system generally In the trial of criminal eases trial by jury is one of the most basic fundamentals of our system of government The Tederal Constitution in Article III which deals with the Judicial Power of the United States guarantees that the trial of all erimes in rederal Courts, except in cases of impeachment, shall be by jury, and the Sixth amendment assures to the accused in all criminal prosecutions the right to a speedy and public trial by an impartial jury The State Constitution likewise contains a provision that "trial by jury in all cases in which it has been heretofore used shall remain inviolate forever" The courts of this State have adopted the general attitude that in felony cases trial by a jury of twelve is a practice that is not to be altered. It has been stated as fundamental that in the trial of a felony the jury trial cannot be waived so as to permit the court alone to hear and determine the matter

Some years ago in an appeal from a conviction of first degree murder, the Court of Appeals voiced an excellent summary of the background of our twelve man jury system, as follows

'From tune immemorial a common law jury has con sisted of twelve men When or how that number ac quired its historic sacredness no one can tell for the origin of the institution itself has been lost in the darkness of antiquity Much less does history inform us with exactness as to the ancient qualifications required of these twelve. There seems to have been a time when they were witnesses who decided cases upon their personal knowledge of the matters in controversy. In the feudal days they were required to be freemen and from this circumstance it may be surmised that some, if not all were owners of property. With the development of evilication and the gradual establishment of property rights there came a period when the ownership of property was probably regarded as something of an index

to the intelligence, character and standing of men in their communities, and as a convenient basis for the arbitrary fixing of a class from which the ultimate selection of jurors was to be made. In England this qualification seems to have been at first confined to such capital eases as treason, misprison of treason and murder: * * * and we know that later it was extended by statute so that when the common law took root in American soil we engrafted upon the jury system the property qualification which to some extent, and in one form or another, has survived to this day. From this short and imperfect reference to the history of the subject we perceive that although the jury as an institution reaches backward beyond the memory or knowledge of man, it has had to be adapted to the ever-changing conditions brought about by the progress of the centuries. Through it all, only two things have remained fixed and The common-law jury must have twelve immovable. men, and these twelve, although taken from a class whose general qualifications may be arbitrarily fixed by law, are chosen by a selective process which, although constantly changing in form, is always designed to secure the service of intelligent and impartial citizens who will be alike the conservators of the obligations of the state and the rights of the individual."

These principles have been so strictly adhered to in New York that where by consent of the parties during a murder trial the withdrawal of a juror was consented to, and the trial proceeded with the remaining eleven, a conviction was reversed solely on the grounds of that irregularity.

The strict manner in which the courts have adhered to the old common law conception of jury trials in felony cases has been relaxed in some other states and within a few years a case was carried to the United States Supreme Court involving the propriety of a trial with less than twelve jurors. In that case the court said:

"In affirming the power of the defendant in any criminal case to waive a trial by a constitutional jury and submit to trial by a jury of less than twelve persons, or by the court, we do not mean to hold that the waiver must be put into effect at all events. * * * Trial by jury is the normal, and, with occasional exceptions,

the preferable mode of disposing of issues of fact in criminal eases above the grade of petty offense. In such cases the value and appropriateness of jury trial have been established by long experience and are not now to be denied. Not only must the right of an accused to a trial by a constitutional jury be jealously preserved, but the maintenance of the jury as a fact finding body in criminal eases is of such importance and has such a place in our traditions, that, before any waiver can beeome effective, the eonsent of government counsel, and the sanction of the court must be had, in addition to the express and intelligent consent of the defendant. And the duty of the trial court in that regard is not to be regarded as a mere matter of rote, but with sound and advised discretion, with an eye to avoid unreasonable or undue departure from that mode of trial or from any of the essential elements thereof, and with a caution increasing in degree as the offenses dealt with increase in gravity."

In a case decided in a Pacific coast state subsequent to the ruling of the Supreme Court, it was well illustrated how strictly the courts construe any ruling which changes the old common law jury system. In a murder trial two alternates had been chosen pursuant to a statute similar to that just enacted in New York. The law provided for them to substitute for a juror who dies or becomes ill. A juror in the course of the trial was excused for other reasons, and the respective counsel stipulated in open court to proceed with the substitute The highest court of that state reversed a conviction obtained under such circumstances, holding that proceeding with the trial with eleven regular jurors and one alternate was improper in the absence of an express agreement made by the defendant himself.

The statutes under discussion are a step in the right direction. It would seem that a similar statute should be enacted giving a judge the discretion to swear an alternate juror in a civil case where it appears to the satisfaction of the court that the trial will be a lengthy one.

CLAIMED INCORRECT DIAGNOSIS OF MASTOIDITIS

A doctor who specializes in ear, nose and throat work was asked by a general practitioner to see a child about three and a half years of age. He called at the boy's home and his diagnosis after examination was infection of the middle ear. He incised the drum of the ear and drained pus, then leaving the child in charge of the family doctor.

About three weeks later the physician who had been called in as a specialist received a call from the parents of the child, complaining that the patient's condition had become worse. He found that the boy had a tenderness and swelling over the mastoids and so, at his suggestion, the child was sent to a hospital for observation. After his condition had been watched for a few days, the doctor had the

boy's head shaved preparatory to an operation, and when the doctor made his final examination preliminary to operating for the child's condition he found that the child had developed on the preceding night a condition of chicken-pox. He, therefore, did not perform the operation but made arrangements for the patient to be removed to a hospital for contagious diseases. That was the last time the doctor ever saw the child.

Repeated attempts to collect his bill for professional services were of no avail, and the doctor instituted suit in the Municipal Court to recover his fee. A counterclaim was interposed by the child's parents claiming that the doctor's treatment had been negligent. The

particular charge was that the doctor had incorrectly diagnosed the child's ailment as mastoiditis, whereas the child was suffering from chicken-pox. As a result of this alleged incorrect diagnosis damages were claimed to have been caused. At the trial the doctor proved the amount of his bill. No competent evidence was introduced to support the malpractice counter claim, and the court therefore directed judgment in favor of the doctor, awarding him the full amount of his bill and dismissing the counterclaim.

CLAIMED FAILURE TO DIAGNOSE PELVIC CONDITION

In this case the plaintiff, a married woman about 28 years of age, came to the office of the defendant doctor, complaining of pain in the region of the lower abdomen. She told the doctor that about three days prior to the visit she felt a pain in this region and that the pain had been continuous since that time. The doctor examined her bimanually, palpated the abdomen and found it very tender in the lower right quadrant. He then fluoroscoped the young lady and at the conclusion of his examination, diagnosed her condition as a subacute appendix with pelvic inflammation. He thercupon explained to the patient the necessity of an operation for the removal of the appendix and she consented to such operation. That very day the patient was operated on by the doctor under general anesthesia. The doctor made a right rectus incision and excised the appendix, which was about two and one-half inches long and filled with feeal matter. This he turned over to the pathologist, who made a microscopic diagnosis of subacute appendix. Before the doctor sewed up the wound he explored the region of the ovaries and tubes and found them inflamed and enlarged. However, because of the age of the young woman and because of the fact that there was no pus in the region of the inflammation the doctor decided to adopt the expectant form of treatment for this condition. He thereupon closed the wound without drains and the patient was returned to her bed. The doctor saw and treated her daily during the two weeks she remained in the hospital. The pain, however, continued and after two weeks the patient left the hospital for her home, where the doctor saw her at frequent intervals. The doctor on these occasions examined her vaginally and instituted tampon treatment and prescribed douches. About a week after the patient had been at home the doctor noticed a slight swelling in the lower right abdomen and advised that she return to the hospital. He had told the patient at the time she left the hospital that if the pain in the pelvic region persisted it might be necessary for her to have a subsequent operation. The doctor was ealled a week later and found her condition to be a little worse, her temperature high and the abdominal swelling more pronounced. At this time the doctor urged hospitalization. The patient refused, and the husband of the patient informed him that he need not return.

Some time later the doctor learned that the woman had been operated on by another physician who removed the right ovary.

An action was instituted by the patient and her husband against the first doctor, alleging negligence on his part in that he failed to diagnose her condition and that he further failed to properly treat her condition.

The plaintiffs failed to demand a jury in this case and the case came on for trial before a Judge sitting as a court and a jury. At the termination of the case the Judge decided that the plaintiffs had failed to prove any charge of malpractice against the defendant surgeon and accordingly directed judgment in favor of the doctor, thus terminating the case.

NOTES NEWS

COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the Medical Society of the State of New York met at the Albany office on July 29th, 1933. There were present Drs. Sadlier, Mitchell, Johnson, and Ross; also President Flaherty, and Executive Officer Lawrence.

Sectional Meetings: The Committee discussed plans of work for the coming year. It approved the plan of sectional meetings that was adopted last year when representatives of the county societies of each district met and reported on local conditions. It was decided to ask the Public Relations Committee of each county society to report on the following questions:

1. Years organized and in active service.

2. Number of meetings held and the subjects discussed.

3. Copies of reports of the committee to the county society, and the action taken on the

4. Reports made by the county representatives on the conferences with the State Committee.

Relation to local health officers.

6. Relation to welfare officers and to other public officials.

7. Relation to voluntary health organizations, such as the Tuberculosis Association and the Red Cross.

8. School health activities.

9. County department of health.

Bulletins: It was decided to send out bulletins this year more frequently and try to arouse the interest of the Committees on Public Relations of the County Societies of the State. These bulletins are to be short, concise, each one driving home some fact in relationships.

Lectures to Medical Students: A report of the lecture given to the students of each of the nine medical schools of the State was made by Dr. Ross who has given the lecture for each of two years. Dr. Ross was selected to give the lecture again next year, and arrangements as to the time it should be given are to be made with the deans of the schools of the State.

Doctor Ross reported that the lecture had been well received this year, that it met with approval of the deans of the schools, and that about fifteen hundred medical students had heard the lecture. In the discussion it was characterized as a definite effort of the practicing physicians of the State to make a contribution to medical education in the student days.

It was developed in the discussion that Syracuse University was carrying on a teaching activity consisting of bringing senior students in contact with actual cases of illness under conditions similar to those of private practice.

Future Work Program: The result of the planning for next year's work of the State Committee on Public Relations may be summarized as follows:

1. Sectional meetings will be held again this

2. The health work in schools will receive increased attention, first, as to efficiency, and then such things as better facilities and other details.

3. Limiting outside activities of full time State This problem largely consists of employees. physicians now employed by the State of New York on a full time basis engaging in the private practice of medicine.

4. The management of state-aided county

hospitals.

5. The leadership of the profession of medicine in planning for the medical care of the hard of hearing.

6. The state orthopedic program.

7. Public health education programs.

8. The profession's relation to public welfare.

9. Preparing the public to oppose unlimited extension of welfare programs beyond the period of depression.

The Com-Examination of School Children: mittee adopted the following outline on the Medical Examination of School Children:

I. From the point of view of the physician:

 Difference between inspection and examination.
 Lack of time for the contraction. Lack of time for thorough examination: Poor cooperation from school authorities. Inadequate compensation. Substitution of nurses' services.

3. Lack of facilities: Room.

Instruments. Family history.

Child's medical record.

4. Inadequate facilities for corrections: Nurse makes contact instead of physician. Report to family:

Negative—value.
Positive—to be checked by family physicians and may or may not be confirmed. Economic condition of family. Handicapped children law.

II. From the point of view of the child:

 Immunization.
 Discovery of defects: Obvious.

Unsuspected. 3. Mental attitude:

Serious. Indifferent. Antagonistic. Dependence upon society. III. From the point of view of the family:

Transfer of responsibility.
 Critical of family physician.
 Objection to financial burden.

4. Inability to appreciate broad scope.

5. Lack of confidence in examining physician.

IV. From the point of view of the school:

Public service to indigent.
 Protection of all.

3. Education toward conservation of health: By example.

By didactic program. 4. Financial outlay:

Cost per discovered defect. Standard routine work. Special investigation: Tuberculosis. Mental hygiene

W. H. Ross, Secretary.

ROCKLAND COUNTY

The Medical Society of the County of Rockland held its regular Summer Meeting on Wednesday, June 28th, at the San Remo Gardens, Stony Point, with thirty-three members present. The President, Dr. S. R. Monteith, of Nyack, presided.

The Chairman of the Committee on Medical Economies presented a minimum fee schedule to

the Society for its consideration.

The president appointed one physician from each township in the county to meet the town welfare officers for the purpose of establishing a standard fee for services rendered to public welfare cases.

The Society voted to hold a clambake the first week in September and to continue the annual post-graduate course in the Fall.

Scientific Session

Dr. Louis C. Kress of Buffalo, Assistant Director-Division of Caneer Control, New York State Department of Health, delivered a concise yet comprehensive address on "Five Year Cures in Cancer," illustrating his discourse with many lantern slides depicting various types of eancer before and after treatment, and also apparatus used in their treatment. The following is the summary made after a recent presentation of a study of 38 eases of five-year cancer eures:

"In the past many members of our profession have had the erroneous idea that eancer is incurable, and it is the aim of the demonstration presented by means of the lantern and slides to correct this impression by showing eancer occurring in different parts of the body, as being cured and remaining so for a period of 5 years ot more.

"Each tumor presented had a biopsy performed, and was definitely proven to be a cancerous neoplasm. Among the different types of cancer shown were lesions on the skin of the face, corners of the mouth, and inner and outer eanthi

Clinical experience has definitely of the eyes. proved that lesions in these locations are very difficult to cure, as are the epitheliomata which involve cartilage; yet these eases have been suceessfully treated and have remained well for five

years or more.

"Caneer of the oral cavity, namely the tongue, floor of the mouth and tonsil, have responded, although they are usually of the pearl cell type and very malignant. Five-year cures of cancer of the breast were shown which were effected by means of the combination of surgery and radiation therapy (high voltage x-rays or radium, both pre- and post-operative). These were not early cases; in fact some of them were far advanced.

"Cancer of the uterus, including the eervix, eervical canal and corpus, were successfully treated by means of radon seeds, radium element pack and high voltage x-rays. Surgery was not employed in any of the cancerous growths of the uterus. Epitheliomata of the vulva, which were usually preceeded by leucoplacie areas, were suceessfully treated and remained well for 5 years or longer by means of electro-endothermy and diathermy, followed by high voltage x-ray.

"Cases of cancer of the rectum, hopeless as far as surgery was concerned, have been cured by means of interstitial radiation with gold radon seeds, radium element tubes and high voltage xrays; although the patients had stricture following this therapy, a colostomy was not performed, but the stricture dilated by means of a rubber bougie.

"We have a eure for cancer, namely surgery, x-ray, and radium. If we were able to see the disease in its early stages and make an early diagnosis, the number of five-year cures would be far greater. Needless to say, the far-advanced eases are incurable, but the same also holds true for diseases other than cancer."

A delightful dinner was served after the scien-

tific session.

WILLIAM J. RYAN, Secretary.

THE DAILY PRESS

MILK CONTROL IN NEW YORK STATE

The newspapers have been carrying news of a milk strike conducted by the dairy farmers of New York State who are dissatisfied with their financial returns. The prices to be paid to the farmers have been set by the official State Milk Board, which apparently doubled the price to be paid to the producer, so that the farmer was getting about four cents per quart instead of about two cents before the board acted. The points at issue in the strike are well set forth in an editorial in the New York Herald Tribune of August 8, which explained that the farmer gets the increased price for only that proportion of milk which is sold for fresh milk consumption; meaning that which goes to market in bottles or cans to be used as fluid milk, while the former low prices prevail for milk used in making butter, cheese and other manufactured products. editorial says:

"The farmer is paid not in accordance with the cost of his milk but in accordance with the uses to which it is put, and he has no control over these uses. In effect, the distributing half of the industry, because of its superior organization, has been able to impose a price structure upon the farmer which makes him carry the whole burden of the surplus. The Milk Board has eliminated some of the more obviously unfair advantages which this gave the distributors-'pooling' arrangements under which the farmer would get surplus prices for milk later actually sold as the fluid-milk retail price are one example—but all this was done at the price of confirming the basic system under which the distributor held his ascendancy over the farmer.

"Since the surplus, in spite of the drought, continues to be large, the farmer continues to suffer.

Toward the end of July Mr. Woodhead returned to Albany with the demand that the whole system of 'blended' prices be abolished and the farmer guaranteed a flat 45 per cent of the total selling price on all his milk. What this amounted to was a demand for a reorganization of the industry to the end that the distributor, as well as the farmer, should share the surplus burden.

"The contrast between salary increases and continued dividends for distributors, and bankruptcy on the farms, lent point to the demand; but the bitter war between the agrarian and industrial halves of the business which it brought to a head was something which the Milk Board evidently had little stomach for. With reason it argued that it was getting increased farm prices, that the Woodhead idea had never been tried anywhere in the country, that many farmers were content to go on with the present system and that it could not yield to a threat. It could also point to its own plans for controlling the surplus, which is the real trouble. But the strike was called.

"It is not really a strike; it is a rebellion. It has to be, until an overwhelming majority of farmers join, because only by violent interference can the milk of non-striking farmers be kept off the market. Governor Lehman has declared that he will maintain order and has called for a special investigation to find out whether the farmers want the Milk Board or not. But investigation will not meet the problem of the strikers. Either the Governor will have to put them down by force or else he will have to organize the structure of the milk industry. It is another case of the truth appearing in the Federal government's efforts at regulation. There is no half-way governmental control."

MEDICAL RACKETEERING

Abuses in connection with medical fees in workmen's compensation cases are the subject of frequent comment in the daily papers and of investigation by State officials. The Grievance Committee of the Medical Society of the State of New York has investigated the problem, but finds no law to support the ethics which governs the medical profession. The Governor's Committee of Investigation recognizes the existence of the evil, but has not produced the remedy. Commenting editorially on the condition, the New York Herald Tribune of July 20, says:

"Mr. Cullman's committee drew up a list of recommendations calling, among other things, for the elimination of fee splitting and commercial clinics and the establishment of a physicians panel system under adequate professional, non-political supervision. These recommendations, designed to meet both aspects of the problem, are now being studied by a committee of physicians appointed by Governor Lehman; but while waiting for their report it is important for the public to bear in mind the reality of the abuse and the necessity for its elimination."

TEACHING PSYCHIATRY

A report on a scientific subject may convey a wrong impression to laymen who do not understand the background under which the report was made. An example is an editorial in the New York Times of July 17, which begins:

"Medical schools of the United States have been woefully tardy in developing department of psychiatry, in establishing standards of instruction in that subject, and in correlating the study of mental diseases with that of physical disorders, according to a report made public yesterday by the National Committee for Mental Hygiene, 450 Seventh Avenue. The data are based on a twoyear survey of the position of psychiatry in medical and lay activities throughout the United States. The entire project was under the general supervision of the National Committee's division of psychiatric education and was financed by the Commonwealth Fund, the New York Foundation, and the American Foundation for Mental Hygiene."

The report deals with the four years of a medical course that leads to the M.D. degree. Laymen do not realize that neurology is distinct from psychiatry, although their fields overlap. The approach to neurology is by way of the nervous system; its anatomy and physiology. This is well

taught in medical schools.

The approach to psychiatry, or the study of mental derangements, is by way of psychology. This is a course in the undergraduate college, and its post graduate study leads to the degree of Doctor of Philosophy, and to a knowledge of mental abnormalities and derangements. Those who have this degree are largely teachers who deal with the prevention of mental disorders. Psychiatrists with the degree of M.D. assume the treatment of these disorders after they have developed into actual diseases or fixed abnormalities.

Psychiatry is the most highly developed specialty in all the field of medicine. The report of the Committee on Mental Hygiene recognizes this fact, and the further fact that the student cannot learn a specialty in the four-year course of a medical school, as is shown by the closing sentence of the *Times* report, commenting on the

medical student:

"But he should be trained primarily to observe and to reason, and to read critically and intelligently, so as to use the findings of other workers. He will be able to obtain further clinical experience in the special departments of medicine after his graduation. We must, in the first instance, train physicians; and, secondarily, train specialists."

TAX ON FLOUR

Physicians, as well as dietitians, will be interested in the tax imposed by the Federal Government on flour, in the interest of the farmer who raised the grain. The *New York Sun* of August 5th explains the distribution of the tax in the following editorial:

"Gross figures on the 30 cents a bushel processing tax on wheat give the ultimate consumer little notion of what it means to him when he buys a loaf of bread. There are few men or women who know how many loaves there are to the bushel, or possess a slide-rule mind to transform the bushel tax into the loaf tax. Variations in recipes would have to be considered. Probably no one figure would apply to every loaf or doughnut, but the Government has established standards which are interesting because they are broken down to tax by the pound. The official tax on a one-pound loaf of bread is \$0.00483. The rates are those which the Commissioner of Internal Revenue has prescribed for collectors who must impose levies upon stocks of flours and flour products according to their wheat contents. Here they are, 0.500 equaling one-half cent:

1.	F	our	•

a)	Whole wheat and graham	.500
b)	All other	704
(c)	Whole wheat and graham	704

Z.	Prepared nour:	
	(a) Doughnut	.401
	(b) Biscuit	.00
	(c) Pancake	493
	(d) Pie crust	.422
3.	Cereal preparations:	
	(a) Whole wheat type	.500
	(b) All others	.7 0-
4.	Bread:	
	(a) All bread except rye	.483
	(b) Rye	
	(c) Zwieback	.462
	(d) Rolls and coffee cake	
5.	Crackers	.690
6.	Pretzels	.732
7.	(a) Macaroni and spaghetti, except canned	.750
	(b) Canned macaroni and spaghetti	
8.	Noodles	
	Paste	
	Foundry molding materials	
10.	Poundry mording materials	.390

"The consumer who wishes to eat wheat but to pay as little tax as possible must turn to canned macaroni and spaghetti; the one who wishes to pay taxes in even figures may use whole wheat and graham flour at one-half cent a pound. The Government figures give some idea of the task imposed on bakers, who must not only pay the tax but explain to the public its effects."

BOOK REVIEWS

Non-Tropical Sprue. A Study in Idiopathie Steator-rhoea. By Th. E. Hess Thaysen, M.D. Octavo of 258 pages, illustrated. New York, Oxford University Press, 1932.

There is a peculiar disease syndrome in which the chief objective symptoms are fatty diarrhea, emaciation, meteorism, stomatitis, and anemia. It runs a chronic course characterized by intermissions and recurring relapses. It has been described under many names and occurs in many parts of the world in patients of all ages. Depending on the place of origin and the age of the patient, it has most frequently been reported as tropical sprue, non-tropical sprue, or coeliac disease in children.

It is the view of Thaysen that these cases represent a unitary symptom complex and are nearly related if not identical conditions which he describes under the heading of idiopathie steatorrhoea. He has collected 26 eases of non-tropical sprue from the literature and adds 8 more from his own experience. The present monograph is devoted to a detailed discussion of the anamnesis, symptomatology, physical findings, laboratory studies, and pathological data obtained in the study of this group of cases. It is possible to differ with the author regarding the interpretation of some of his metabolic studies in relation to the pathogenesis of the condition. These are minor details, for until the etiology of these various conditions is established it is manifestly impossible to either prove or disprove the author's thesis.

Thaysen has done the medical profession a service in ealling attention to the frequency of non-tropical sprue. This monograph is an excellent presentation of present day knowledge, or lack of it, of an important but little understood group of diseases. Solution of the problems raised awaits further study which should be stimulated by Thaysen's report. The format, illustrations, bibliography, and index are excellent. CARL H. GREENE.

THE RISE OF PREVENTIVE MEDICINE. By SIR GEORGE NEWMAN. M.D. Octavo of 270 pages. illustrated. New York, Oxford University Press, 1932. Cloth, \$3.00. (University of London Heath Clark Vectures (University of London Heath Clark Lectures,

The author of this volume has an international reputation in the Public Health field, and now presents in book form a series of lectures delivered by him at the London School of Hygiene and Tropical Medicine in 1931.

Beginning with the early days of folk-lore and magic, Newman shows their relation to the preservation of life, as evidenced in the quest of food and the general strug-gle for existence. From this point, he traces in the medical history of Egypt, the Hebrews, Greece and Rome those measures which indicate a recognition of hygiene and sanitation.

In the Middle Ages, the advances of Preventive Medicine are shown in the social attempts at defence against famine and pestilence. It is in the Renaissance Period, however, that the rise of modern Physiology and the introduction of experimental and scientific methods laid the basis for modern medicine, and this holds true also with respect to measures of a sanitary and communal protection character.

Every physician of course should be familiar in a general way with the history of medicine as a background for intelligent approach to modern problems. With growing interest in Preventive Medicine, this book provides information of its development in a concise way.

A. E. Shipley.

SEX AND INTERNAL SECRETIONS. Edited by Edgar Allen. Oetavo of 951 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$10.00.

Investigations concerning the endocrine aspects of sex have made tremendous strides in recent years. The discovery of the ovarian and male sex hormones together with the sex hormones of the pituitary have revolutionized our concepts. The number of papers concerning this topic and the sometimes contradictory evidence makes it exceedingly difficult for the medical profession to get a elear pieture of the present status of knowledge. Allen and the numerous contributors to this volume can claim credit for a splendid accomplishment. They have colleeted in a systematic and precise way all the evidence available at present, which enables the reader to obtain a rather clear pieture of this so involved subject.

Their survey differs from most others inasmuch as it has been compiled by those men who did most of the original work themselves and have full authority to discuss the matter and judge conflicting opinions accord-

ing to their merits.

After a general biological introduction by Lilly, the interrelation of genic and endocrine factors is discussed by Danforth. Chapters of general biological interest are contributed by Bridges, Willier, Witschi and Riddle. There is a chapter on the biology of the testis by Moore and one on the biochemistry of the male sex hormone by Koch. The ovarian follicular hormone is discussed by Allen and its biochemistry by Doisy. Hisaw presents the physiology of the corpus luteum and Turner that of the manuary glands. The important plumage tests in birds are amply discussed by Domm and others, and so is the question of ovulation and fertilization by Hartman. Smith and Engle present the relation of the pituitary gland and pituitary hormones to the sex glands and contribute a much welcomed discussion of the hormones found in blood and urine. Two final chapters on the sexual drive by Stone and on endoerine disorders in men by Pratt complete the volume. With the exception of the last mentioned chapter which attempts to dispose of a variety of rather complex problems on 30 pages and falls somewhat short of its aim, all others are exceedingly well written, competent and thoroughly inclusive. The volume as a whole represents one of the most valuable callists. able additions to the literature of endoerinology published in recent years.

M. A. GOLDZIEHER.

PREVENTIVE MEDICINE. By MARK F. Boyd, M.D. Fourth cdition. Octavo of 532 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$4.50.

This book of over 500 pages has been earefully read by the reviewer from cover to cover and he has no hesitancy in stating that it is probably the best work of its size on this subject which has yet been written, certainly the most workable and readable book that has come to his attention. He has followed the unusual course of keeping it on his desk for a number of weeks where it has been freely consulted by himself and other

Department of Health workers always with satisfaction.
In the first two-thirds of the book Dr. Boyd treats of the Diseases due to Invading Micro-Organisms in a most thorough and satisfactory manner, discussing among many subjects Sources of Infection, Dissemination of Infective Agents, Contact Transmission, General Measures of Disease Control, Disinfectants and Disinfection. Excreta Disposal, Relationship of Water to Health and Disease, Water Purification, Milk as a Route of Infection, Its Production and Inspection, Other Foodstuffs as Route of Infective Production of Infection of Infective Production of Infective Pr as Routes of Infection, Insects as Vectors of Infective

The remaining one third of the book is Agents, etc The remaining one third of the book is devoted to Deficiency Diseases Occupational Diseases, The Puerperal State, Heredity and Disease, Special Aspects of Hygicne and Sanitation Demography and Public Health Administration The index is adequate. The book is well balanced, shows a good sense of values in the selection of matter omitted as well as included is written by one who thoroughly knows his subject and his recommendations are in keeping with the best modern Department of Health procedure Only such charts graphs and tables of statistics are included as are necessary, a surprisingly small number when the nature of the book is considered. A most satisfactory work not only for those engaged in public health work but also for students and general practitioners

THE MANAGEMENT OF ARDOMINAL OPERATIONS By New York 12 Management of Albominal Operations By New York 12 Management of Albomina Operations By New York 12 Mana RODNEY H MAINGOT M D 12mo of 311 pages York, William Wood & Company, 1932 Cloth, \$225

The plan of this manual is well conceived, the material segregated into convenient chapters and discussed at

length

Many statements however, will not find acceptance by American students and surgeons So for instance, the opinion of the author that a mixture of chloroform and ether with oxygen is the best anesthetic in operations for a runtured viscus or other emergency cases, or the advisability of giving sod bicarbon in warm water im mediately after operation to relieve the patient of the

inhaled anesthetic by forcing vomitus

The American School of Surgery has outgrown many
of the precepts laid down by the author, thus making it difficult to evaluate this book as a whole As a textbook for beginners it may be misleading other books on the same subject giving information more in accordance with the teachings on this side of the Atlantic Ocean

GEO WEBB

A SYNOPSIS OF SURGICAL ANATOMY By ALEXANDER LIFE MeGRECOR 12mo of 609 pages illustrated New York, William Wood & Company, 1932 Cloth \$450

A very remarkable volume of anatomy contained in 580 pages including in its text a short but very lucid description of the common dislocations and fractures as well as other important surgical data. The illustrations are diagrammatic and serve the purpose excellently

The reviewer heartily recommends this book for every surgeon's desk and predicts that it will never be placed GEO WEBB into the bookcase

CLINICAL PHYSIOLOGY OF THE LAF By FRANCIS H
ADLER MD Octayo of 406 pages illustrated New York The Macmillan Company, 1933 Cloth, \$500

The things we read about in text books are usually taken for granted that one rarely, if ever, disputes the sources of such established data. These principles be come so woven into our mental processes through an thoritative teachings that there seems to be little or no room for flexibility

On that account this book by Adler should ring a new note in medical concepts. It has so coordinated re search physiology with ophthalmologic practice as to make us seek the basis for everything supposedly factual Many a book is valued only for the 'meat' it contains This book by Adler does not fall into this category It is stimulating in every paragraph and brings the reader into a world of creation and ideas. Those readers who enjoyed Hilton's book on Rest and Pain' will find added pleasure in this work because it so encompasses our knowledge of minute eye functions in terms of neuro anatomy

That the eye is a camera in fact as well as in theory

is described in actual experiments on animals showing the changes in visual purple in areas corresponding inversely to that of the object seen or focussed upon The experiments leading to such convincing deductions are inspiring and very fascinating. The determination of the duration of the various components constituting the light reflex by means of motion pictures is another instance whereby medicine has harnessed other branches of scientific knowledge to convert theory into fact

These and many other details make this book one of the very finest which has come to this reviewer's attention EMANUEL KRIMSKY

CALCIUM METABOLISM AND CALCIUM THERAPY Second continum By Abraham Cantarow M D 12mo of 252 pages Philadelphia, Lea & Febiger, 1933 Fabrikord \$2 50

The second edition of this book is a revision and supplementation of material presented in the first edition We appreciate now, more than ever before, the im-portance of the proper understanding of the physio logical indications of calcium therapy. It is therefore essential that the specialist as well as the practicing physician acquaint limself with the true actions indications and limitations of this chemical. Few changes have been made in this edition, but previous controversial points are brought up to date. Among these discussions are found a conception of the relationship between the parathyroid hormone and vitamin D, the relation of the calcium and phosphorous intake to the effects of vitamin D and the parathyroid hormone, the significance of the phosphatases in the mechanism of ossification and in bone diseases dental caries the influence of calcium upon the action of other drugs calcium in nephritis and tetany, the nature of the parathyroid hormone action

The reviewer recommends this book to the laboratory worker and especially to the practicing physician, because it discusses all the phases of the present important subjects of calcium metabolism and therapy S J Cohen

THE PRACTICAL MEDICINE SERIES Comprising Eight Volumes on the Year's Progress in Medicine and Surgery Series 1932 Chicago, The Year Book Publishers (c 1933) Obstetries Edited by Joseph B DeLke M D Gynecology Edited by J P Green-\$2 50

These abstracts from the obstetrical and gynecological literature of 1932 have been selected by the authors with their usual care and discrimination. The book fills its purpose admirably DeLee's parenthetical comments, often facetious occasionally caustic, always pointed are priceless CHARLES A GORDON

The Organs of Internal Secretion By Ivo G Cobb M D Fourth Edition Octavo of 303 pages Balti more William Wood & Company, 1933 Cloth \$350

This is the fourth edition of a book which was first published in 1916 and which is now presented as having been completely revised and brought up to date

Unfortunately the author has included too many parts of the original edition which are now out-dated and has failed to include more than passing mention of the numerous advances which have been made since then

This is especially true in the consideration of the parathyroid adrenal cortex and anterior pituitary hormones

The chapter on obesity is fairly well handled

The presentation in general is quite sketchy and does not add much to the knowledge of the reader who is unacquainted with the subject M B Gorpon

OUR NEIGHBORS

COUNTY SOCIETY NEWS IN MISSISSIPPI

The May issue of the New Orleans Medical and Surgical Journal has a Mississippi section which contains a report of the Annual State meeting May 9-11, 1933, in Jackson. A feature of the account of the meeting is a report from each county society, 26 sending reports and 54 failing to reply.

The reports are unique and show both humor and sympathy. The editor from Granada

County writes:

"Only a line to answer 'roll call."

"Nothing of particular interest has happened since my last report. The health of our county is exceptionally good. The doctors are all at their posts; they and their families well, no changes in our personnel, no deaths or births or removals.

"We are looking forward to the state meeting next month and anticipating a good meeting.

"More anon."

The doctors of Issaquena County are doing their duty cheerfully, as the following letter proves:

"The horde of doctors in Issaquena have been living off the fat of the land since the R. F. C. began operations in our county. Those of us who heretofore have given both our services and our medicines free of charge to all comers are now being paid for our medicine by the R. F. C.

"In some instances we are receiving pay for our visits at the rate of \$1.33 per visit. For this we are thankful. True there are ups and downs to it. Some visits are far, and some are near. One doctor drove five miles in his car to the jumping off place. Then he put on his rubber boots and walked a mile farther to get to the patient. Another made a night trip out eight miles to attend a complicated case of labor, adherent placenta, and received the usual \$1.33 for it. Probably better than nothing. With their limited means the R. F. C. cannot afford to give any more.

"The country is flat broke. No money to pay nothing. But the country doctor has to go to these cases. He cannot turn them down because they have no money, and never will have any. He cannot tell them to get another doctor, because there ain't no other doctor. He cannot dodge the responsibility."

The Tate County editor writes:

"The Tate County Medical Society meets every first Wednesday night. However, we

have not been meeting regularly for some time. We hope to begin again at once. We always get lots of good out of our meetings even if only a few are present. Every member has something that will help the other members.

"There have been several people in the county bitten by rabid dogs during the past month, but all are taking treatment and doing fine, so hope there will be no further trouble; also several cases of diphtheria, but all exposed have been vaccinated, and the disease will soon be checked. There have been over 1,100 vaccinated against diphtheria during the past year in this county and we have only a part time health office; nearly 2,000 against typhoid and something over 1,500 against smallpox."

The editor from Montgomery County goes in for personals:

"We have very little to report. The doctors all seem to be fairly busy. Since our last report we have had only one new doctor added to our county, Dr. Oliver, of Dutch Hill. We wish him success in his new field of practice.

"Dr. and Mrs. James P. Ward are visiting in Winona.

"Mrs. Oscar Ringold of Dallas, Texas, is visiting in the home of her father and mother, Dr. and Mrs. J. O. Ringold. She will be here until Dr. Oscar Ringold returns in June.

"The doctors' collections seem to be a little short, but I guess things will soon be better."

The Pearl County editor says:

"There seems to be comparatively little sickness in the county other than appendicitis and other such surgical conditions. And lest we forget, the birth rate in this county has not decreased at all since so many people have become indigent, banks have closed and physicians can not collect their fees. A rather large number of acute surgical cases have developed since the banks have been closed. The incidence of acute communicable diseases is very low, however, much to the gratification of all concerned. And the county health department is making every effort to see that this shall obtain at all times.

—"The hospitals of the county are having their troubles just as do individuals. They are still operating but under many handicaps. That goes, however, for all such institutions I judge."

(Continued on page 1018-adv. xii)

There is Greater Margin of Safety

in Dextri-Maltose

The Dextri-Maltose Group

Dextri-Maltose No. 1 (with 2% sodium chloride), for normal babies Dextri-Maltose No 2 (plain, salt free), for salt modifications by the physician Dextri-Maltose No 3 (with 3% potassium bicarbonate), for constipated babies Dextri-Maltose With Vitamin B" for its appetite-and-growthstimulating properties and the prevention of nutritional anemia (also supplies 24 mg. iron and 0 57 mg. copper per oz.).

Samples on Request.

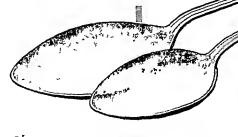

Tothing tells more graphically the story of greater safety—the freedom from nutritional disturbances in infant feeding that goes with the use of Dextri-Maltose, than the circumstances surrounding its introduction in England.

In England, as in America, it had been prescribed-for modifying cow's milk-by the level tablespoonful.

It was not until Dextri-Maltose had been used in England for over three years, that a prominent English pediatrist pointed out that the British tablespoon is twice the size of the American The English level tablespoon holds 1/2 ounce of Dextri-Maltose, the American, 1/4 ounce. Where 6 American tablespoonfuls had been prescribed in 24 hours, the infant was actually taking 12, or, in other words, instead of the usual 11/2 ounces per 24-hour period, the carbohydrate addi-

3 ounces. However,

Comparative Sizes of English and American Tablespoons

Despite the continued use of twice the usual amounts of Devtri-Maltose in England, nutritional disturbances were a rarity. It is doubtful if any other carbohydrate could have been used in such excessive quantities with equal immunity from serious results.

A Few Indications for

PHILLIPS' MILK OF MAGNESIA

EXCESS GASTRIC ACIDITY—

One or two Phillips' Milk of Magnesia Tablets (each equivalent to a teaspoonful of Genuine Phillips' Milk of Magnesia) is usually sufficient to bring about a marked reduction in the gastric juice acidity. Phillips' Milk of Magnesia in liquid form gives the same beneficial results.

A GENTLE LAXATIVE-

Phillips' Milk of Magnesia has for years been a standby in pediatric, obstetrical, and general practices, because of its mild yet efficient action, pleasant taste and absence of uncomfortable after-effects.

IN THE MOUTH—

Where the saliva is acid, Phillips' Milk of Magnesia may be used in any of three forms—liquid, tablet, and Dental Magnesia. All three tend to neutralize the acids formed by the pathogenic oral bacteria, and likewise prevent their growth.

PHILLIPS' MILK OF MAGNESIA

The doctors of Pontotoc County seem to be

having a good time.

"We are glad to welcome Dr. C. W. Patterson to our county. Dr. Patterson moved to Houlka, R. 3, from Reid.

"Dr. J. A. Donaldson, of Okolona, died at

his home one day last week.

"Very little sickness in the county now. Usually see three or four out-of-town doctors in town every day. Some of them have begun to get fishing in their bones. Quite a number report that they expect to attend the meeting of the State Medical Association in Jackson, next month. We hope to have a good crowd from Pontotoc County.

"Dr. J. M. Hood, of Houlka, was a visitor

in town one day last week.

"We have had a few rabid dogs in the county in the past two weeks, but fortunately have not had any one bitten so far.

"Will ring off for this time."

EMERGENCY RELIEF IN DELAWARE

The June number of the Delaware State Medical Journal contains the following official statement by the Relief Directors of the Temporary Emergency Relief Commission regarding fees to physicians:

"At a joint meeting of the Relief Directors of the Wilmington-New Castle County Area of the State of Delaware Temporary Emergency Relief Commission, and physicians representing the State and County Medical Societies, the following rules and charges were agreed upon and will go into effect immediately:

"1. It was agreed that the fee charged for the initial visit of a physician to one of our relief cases should be fifty cents, and thirty-five cents for each subsequent visit. (The 'fees' mentioned here are not regarded actually as fees, but as reinbursements for expenses incurred, chiefly in transportation. The word 'allowances' would be more descriptive.)

"2. The initial visit shall be construed to mean the first visit made by the physician on any one spell of sickness, and that two initial charges could not be made on the same sickness of any

one patient.

"3. Twenty-five cents was the amount agreed

upon as a fee for all office calls.

"4. In cases of pregnancy and miscarriage, the patients should be sent to a hospital. When it is impossible to admit them to a hospital, the charge for treating them at home should in no case exceed \$15.00, this charge including all supplies used in connection with the case such as bandages, etc.

"5. In cases of pneumonia, and long-time illnesses where the physician must make more than one call a day, in order to watch the disease, re-

CURITY

offers these

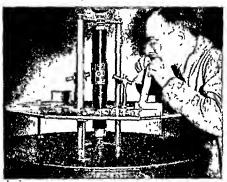

ADDITIONAL SAFEGUARDS to dependable absorption

Absorption — one of the most important requirements of a suture, is also a hidden characteristic. You can't see it, you can't feel it, you can't measure it. Curity does that for you by its development and use of safeguards that guarantee definite and measured suture absorption.

Chemical Digestion Test

As a final, extra cheek on absorption Curity Satures are tested by the chemical digestion process, developed in the Curity Laboratories. In the sbort space of twenty-four bours this test reveals the behavior of the suture as it would occur over the longer periods of time it would require to be absorbed by actual body tissues. The action of the suture is observed in a complex solution that simulates body fluids, and the results must cheek against the results obtained in the customary animal test . . . Curity suture absorption is measured and controlled!

X-Ray Diffraction Research

An X-Ray technique has recently been developed that now makes it possible to do basic research on catgut structure that is revealing hitherto unsuspected facts. Curity Snture Laboratories recognized the importance of this new research tool and use X-Ray Diffraction equipment for such study. While all catguts are essentially the same chemically, their structural make-up may be totally different. Two pieces of catgut may exhibit very different absorption characteristics. For the first time through the X-Ray, this difference can be definitely predicted.

imbursement will be made for each call made.

"6. Where more than one person is treated in a family at the same time no extra charge will be made, except the actual expense of bandages

or medical supplies used.

"7. When the physician is called in on a case, without the authority of the case worker, the physician should call the case worker and obtain authorization before making the call. The only exception to this rule being on Saturday afternoons and Sundays when our case workers are not on duty."

CANCER CONTROL IN KANSAS

How the Kansas Medical Society is dealing with the Cancer problem is told in the following editorial in the July number of the Journal

of the Society:

"The outlook for a practical program of cancer control rests upon an educational foundation. Present misconceptions in the public mind and a certain amount of pessimism in the professional mind must be replaced with constructive facts and a knowledge that cancer is being cured in an encouraging number of cases.

"The profession should realize that cancer is not a one man disease; its diagnosis and treatment require the services of the pathologist, radiologist and internist in addition to the surgeon who may be in charge of the case. Each of these specialists has a contribution to make to the diagnosis and treatment of the case. Special facilities are also necessary to care for cancer patients in keeping with our present knowledge of diagnosis and therapy of this disease. The interest and cooperation of hospitals, therefore, is essential to the rendering of an adequate service to cancer patients, and so a program of coordinated and cooperative effort is required for the development of a practical and effective program of cancer control in any community.

"The Kansas Medical Society has accepted the responsibility for the cancer work in this state, and has shown its interest in practical and constructive ways. A permanent committee of the Society has been formed to consider the various aspects of the problem. A symposium on cancer was presented at the last annual meeting. The papers of this symposium appear in this issue of the Journal and should

be read by all members.

"Perhaps the most significant evidence of the interest of this Society was the invitation extended to the American Society for the Control of Cancer to make a survey of the cancer problem in Kansas, reporting its findings with recommendations to the Society. This survey

(Continued on page 1021-adv. xv)

(Continued from page 1020-adv. xiv)

will be a fact finding undertaking and will bring together for the first time reliable data on facilities in the state for diagnosis and treatment of cancer, their distribution and how used; on the number of cancer patients hospitalized, and the distribution of cases and deaths throughout the state. The report of this survey, when submitted, should point the way to an improved service to sufferers from this disease and coming, as it will, from an impartial and unbiased source should commend itself to the thoughtful consideration of this Society. Similar surveys made in neighboring states, Colorado, Iowa, Minnesota and Wisconsin, have been accepted by the medical profession in those states and the recommended program put into effect as far as local conditions permitted."

APPENDICITIS DEATHS IN MASSACHUSETTS

The New England Journal of Medicine for May 11th contains the following account of a plan for encouraging the early diagnosis and treatment of appendicitis, thereby reducing the death rate from the disease:

'Massachusetts has shared in the increase in fatality of acute appendicitis which has become evident in the United States during the past twenty years. The plan for reducing this mortality which was successfully carried out by the Philadelphia County Medical Society in 1931, suggests that similar results might be obtained in Massachusetts. Representatives of the State Department of Health, the Boston Retail Druggists Association, the Massachusetts State Pharmaceutical Association and the Committee on Public Health of the Massachusetts Medical Society have conferred and decided to project a publicity week, similar to that organized by the Philadel-phia Society. The date fixed for this was the week of June 12.

"The wording to be used on posters and all other printed matter has been carefully edited by the Committee on Public Health with the aid of selected surgical consultants. It is hoped that a measurable reduction of the time lost between the onset of the pain and the seeking of medical advice will be observed here, as it was in Philadelphia where one hospital reported a reduction of twenty-five per cent in this lost time, together with a reduction of nearly fifty per cent in the mortality of acute appendicitis after the publicity period. Several of the larger hospitals are already cooperating with the State Department to secure controlled data from which the effects of this campaign may be judged at a later date.

"The Committee on Public Health plans to furnish to the Fellows of the Society, on request, 3x5 cards on which the following will be printed: (Continued on page 1022-adv. xvi)

Importance of milk in the adult diet

MILK is the one food for which there can be no effec-tive substitute. But many adulta dislike milk; often those who need it most soon tire of its taste and color.

However, Cocomalt mixed with milk produces a delicious, chocolate flavor drink which is tempting to children and grown-ups plike. Prepared as directed, it increases the caloric value of milk more than 70%-adding extra pro-

Not only in sickness and lactation, in gener for optimum well-being

recommended. Every glass, properly prepared, is equal in caloric value to almost two glasses of milk alone. Delicious HOT or COLD. In 1/2-lb. and 1-lb. cans at grocery and drug stores. Or in 5-lb. cans at a special price for hospital use.

Free to Physicians

We will be glad to send a trial-size can of Cocomalt to any physician requesting it. Mail coupon below.

For Summer Skin Affections

In most summer skin affections the first desideratum is prompt relief from the intolerable itching. Then follows in order, destruction of the toxins, reduction of the inflammation and toning of the integument. Hydrosal (Liquid or Ointment) serves these purposes admirably.

It offers the old "standby" Burow's Solution in its true colloidal form. Stable, uniform, free from all impurities. Hydrosal Ointment is designed for use where a prolonged action is desired. It contains 50% colloidal aluminum acetate in an anhydrous lanolin base.

MALPRACTICE INSURANCE IN COLORADO

The July number of Colorado Medicine has the following announcement regarding increased rates for malpractice insurance:

"The Ætna Life Insurance Company has been writing a large number of the members of the Colorado State Medical Society for the past eighteen years at a very low rate, but the matured results indicate the necessity for a material increase in the rate for this form of insurance at this time.

"Insurance executives tell us privately that, in the last analysis, doctors themselves must assume whatever responsibility for the increase is not directly traceable to the economic conditions of the times. Almost every malpractice claim, their records show, has had its inception in criticism of a doctor by one or more of his colleagues, criticism usually thoughtless or careless, but too often criticism born of personal animosity.

"Thus it develops that continuance of the new higher rates will depend very largely upon the attitude of our Colorado profession, both individually and collectively. Greater care on the part of physicians and individuals when discussing treatment of a patient by a colleague, greater care in avoiding the unjustified criticism that a patient uses as the basis of a suit, greater unity of organization and closer cooperation in defeating the many claims and suits that have no fair foundation and amount to little better than extortion—these may in the not too far distant future bring malpractice premium rates back down.

"In the meantime, while rates for members of the State Society have increased, those for non-members are still higher. The man who keeps himself in good standing in the Medical Society still gets his malpractice insurance cheaper than can anyone else. The reduction for all but the smallest policies amounts to more than the medical society dues."

COMPULSORY MEDICAL CARE IN NEBRASKA

The June issue of the Nebraska State Medical Journal contains the following report of the decision of a county judge that a county must furnish medical aid to the needy, as is the law of New York State under the present Welfare Law.

"It takes a judge to every now and then tell the county boards that physicians have rights in connection with the care of the paupers and indigents, that the boards are bound to respeet. Judge Blackledge of Adams county informed the county board of that area the other day that it has a responsibility with respeet to earing for the sick. It was a case wherein the board refused to provide hospitalization for a person who needed it. The court pointed out the plain duty of the local government, at the same time declaring it is the duty of the board to use discretion and judgment in its use of public money. The judge said the board was compelled by law to furnish medical treatment to persons, whether residents of the county or not, who had no means of procuring treatment and who were found to be in need of attention by a physician or surgeon."

conservatively. Cancer is usually secondary to a lesion in the breast or genito-urinary tract. In this connection should be emphasized the great relief afforded patients suffering from this very painful affection by adequate x-ray treatment or by sectioning the antero-lateral pain tracts in the spinal cord above the lesion—cordotomy, as suggested by Spiller and developed by Frazier and Spiller⁵ and by Peet, and others. Multiple myeloma may give rise to repeated fractures through the punched out rarified areas scattered throughout the skeleton. The blood may show high grade anemia or simulate lymphatic leucemia, and the urine may show Bence-Jones protein.

The commonest acute joint disease is rheumatic There has lately been some tendency to confuse this malady with the chronic arthritides, merging them in statistical studies designed to bring out information concerning the pathogenesis and nature of so-called "arthritis." I plead for a place for rheumatic fever as a distinct entity, differing essentially from every other type of arthritis? The distinctive tendency to rapidly rotating large joint involvement, the typical cardiac and central nervous system attack, and above all the characteristic architecture of the cellular pathology, as seen in the Ashoff body and subcutaneous nodules, seem to outline and define the disease as a distinct clinical entity. Do these same factors not further strongly suggest that the disease is caused by one specific organism and not by any one of a group of more or less related organisms, as has been lately suggested?

In such a brief review as this no attempt will be made to discuss the diagnosis, which is sometimes a bit tricky, but some points in treatment will be discussed.

Given an acute, febrile polyarthritis of the rheumatic type, the fashion, and a wise one I believe, is to turn to sodium salicylate as the most important therapeutic defense. There is an art in its use which is worth cultivating, as the drug is utterly useless in too small doses and is dangerous in excess. For the average adult twenty or thirty grains every three hours, with a like amount of sodium bicarbonate, will usually be required. In the absence of complications the temperature usually drops to about normal within two to four days, and the painful joints are controlled at the same time. True, both fever and arthritis are very apt to recurr, particularly if the dose of the drug is much reduced, but many times the attack once controlled in this manner, goes on to healing without interruption.

But suppose the disease is not controlled by three or four days of this dosage, what then? One should think of complications such as carditis, and recheck the original diagnosis. With rheumatic arthritis still as the challenger can the drug be further pushed? If the patient is tolerating it well, a slight increase may be cautiously tried but over 200 grains a day is definitely over

into the danger zone. Fatalities have been reported from 75 to 180 grains (Sollman). The dangerous symptoms of salicylates are the cerebral symptoms, delirium or unconsciousness, and dyspnea. Much less serious and much more common are the gastric symptoms. With an irritable stomach one may well turn to rectal injections. A teaspoonful of sodium salicylate in 4 oz. of starch water per rectum is often quite effective. This may be used twice a day, and it is well to add 15 to 20 drops of laudanum to each dose.

Where salicylates are badly tolerated pyramidon (amidopyrin) in 10 gr. doses every three hours sometimes acts very well. An obstinate rheumatic arthritis can often be promptly terminated by a few doses of typhoid vaccine intravenously. The initial dose should not be over 10 million organisms. During convalescence from rheumatic fever iron in large doses is nearly always needed.

May I remark in passing that I have never seen salicylates have any effect upon rheumatism of the heart?

Another form of acute arthritis is Schönlein's disease, or rheumatic purpura, in which a typical purpuric eruption, often combined with urticarial lesions, is associated with a rather mild polyarthritis, the heart being entirely unaffected. True rheumatic fever may begin with urticaria so that the distinction is not always easy. The tendency for rheumatism to migrate from one large joint to another and to involve the heart, and the absence of hemorrhagic lesions will usually differentiate the two conditions. Arthritic purpura is now known to be an allergic disease and treatment on this basis brings much more satisfactory results. Sometimes the offending antigen can be discovered through history or skin tests. I have found the intravenous injection of 1 or 2 c.c. of a 5 per cent peptone solution every 3 or 4 days to be very helpful in this notoriously obstinate dis-

care. Chronic arthritis is usually divided into the atrophic and the hypertrophic types, and in their pure forms these conditions are quite distinct. The atrophic arthritis tends to occur in younger individuals, sometimes exhibits acute febrile exacerbations, is usually characterized by a rapid pulse, a tendency to sweat and various vasomotor faults, and leads to marked wastings and deformities but not to bony ankylosis. The hypertropic form lacks most of these clinical characteristics, occurring typically in older and stouter people and probably nearly always bearing a definite and probably nearly always bearing a definite relationship to trauma or strain of some sort. Pure types are probably rarer than those which present some characteristics of both, which is important from the standpoint of etiology, pathology and treatment. Infection no doubt plays some part in every case of atrophic arthritis and we always search for and remove all possible foci. Even with the hypertrophic form this should not be omitted. Descusitizing vaccines and immunizing protein shocks are often valuable when infection plays a part. Personally I have got most help from very small doses of mixed strains of Streptococci all of which were recovered from arthritic patients, as worked out by Burbank, and from colloidal sulphur used intravenously. Neither should cause any systemic reaction. General measures, carefully individualized, are of the greatest importance. Rest for the tired, reducing for the overweight, iron and arsenic for the anemic, digestive survey and correction. orthopaedic assistance, particularly for the feet, which affect so vitally all the structures of balance, carefully checked physiotherapy with particular emphasis upon exercises, active and against resistance to reduce muscle spasm, and finally optimistic moral support and everlasting perseverance are all indispensable.

Gout can have but little space this afternoon, but we should not forget its existence. It is commoner than we give it credit for. There is a very striking case on my service at Long Island as I write. Gout can usually be promptly identified by its trade mark, the tophus. If you can have your way with a patient about diet, exercise and

fresh air you can do a great deal if the diseasc is not too far advanced. The older patients with ehronic ehanges are more difficult.

Syphilis practically never causes a polyarthritis except with the dactylitis of early hereditary syphilis or the very mild joint swellings that sometimes come with the secondary roseola. An obstinate monarticular syphilitic arthritis, resembling tuberculosis occurs in hereditary syphilis.

Tabes dorsalis or syringomyelia may cause the curious trophic changes in one or more joints which we know as Charcot's joints. These are painless swollen joints with considerable destruction and a rather characteristic hypermobility, giving almost a flail like effect. They may require mechanical support and protection.

THE DIAGNOSIS OF DISEASES OF BONES AND JOINTS And a Few Remarks Concerning the Diagnosis of Fractures

By FRANK S. CHILD, M.D., PORT JEFFERSON, N. Y.

Read hefore the Second District Branch of the Medical Society of the State of New York, in Garden City, Long Island, on Nov. 17, 1932, in a symposium of six papers on "Diseases of the Bones and Joints" presented by Long Island physicians

ANY of the deformities which the orthopedic surgeon is called upon to treat are caused by infections of the bones and joints. Prevention of these deformities begins with early diagnosis. By this it should not be understood that every deformity can be prevented but early diagnosis followed by properly instituted treatment will ameliorate or prevent deformity in many cases.

Acute Infectious Osteomyelitis

Acute infectious osteomyelitis is the commonest destructive process in the bones of children. Staphylococcus aureus is the organism most frequently causing this disease. The infection is usually blood stream, commonly arising from some distant focus as infected tonsils, middle ear, furuncle, etc. A preceding injury is a frequent contributing cause.

It is a characteristic of this disease, in children, that the infection practically always begins in the growing end of the bone, except of course in those cases in which there is a direct infection. Thus the disease begins in close proximity to, but not in, the joint.

The onset is sudden and severe, usually with a chill, sometimes with a convulsion. The symptoms are those of a severe septic infection. Death may ensue before local symp-

toms become pronounced.

In making the diagnosis careful palpation is most important, for in the early stages localized tenderness is frequently the only clue. Other signs as swelling, local heat and redness may not appear until a few days later when the disease is well developed in the bone. The patient may be delirious, or too sick otherwise to complain of any localized pain, and to elicit local tenderness every long bone should be carefully palpated. Increased pressure at the point of local tenderness will cause exquisite pain.

The X-ray is of value only for its negative findings, for bone changes cannot be demonstrated in the early stages.

The blood culture, taken early, is positive in a large majority of eases,

Important diagnostic signs are:

- 1. Sudden onset and high fever
- 2. Generalized sepsis 3. High leucocytosis

4. Intra-osseous pain without swelling

5. Exquisite pain on pressure at point of local tenderness

6. Swelling absent early, present after few days

Sometimes it happens that the physician does not see the disease until it is well ad-Then the picture is different. The high fever and delirium may suggest typhoid fever. The swelling near the joints may suggest rheumatic fever or primary cellulitis. A milder fever and swelling may be suggestive of tuberculosis of the joint.

In this stage bone destruction has occurred and the X-ray will easily differentiate from typhoid and rheumatic fevers, but not so easily from tuberculosis. Cellulitis is a late develop-

ment of osteomyelitis.

Chronic osteomyelitis must be differentiated from syphilis and sarcoma.

Acute Infectious Arthritis

Acute infectious arthritis may begin as an infection of the synovial membrane or it may be secondary to osteomyelitis, a complication occurring in the hip joint. In primary form it is a blood stream infection arising from infection in the tonsils, teeth, accessory sinuses of nose, furuncles, etc. It may also follow as a complication of measles, scarlatina, pneumonia, meningitis or smallpox.

The onset is sudden with high fever and symptoms of severe sepsis. The joint involved is very tender and there is fluctuation.

local heat and redness.

X-ray findings are negative in the early stage but after the disease has continued several weeks bone changes will be evident.

The acute stage of infectious arthritis may be confused with osteomyelitis, bursitis, teno-

synovitis and inguinal adenitis.

The subacute stage may simulate a low grade infectious arthritis and be mistaken for tuberculosis. Aspiration of the joint fluid and laboratory examination will aid in the tuberculosis. differentiation.

The bone changes appearing in the subacute stage, as seen by X-ray, begin as erosion on the superficial surface of the cartilage. This differs from tuberculosis as in this disease the erosion begins on the under surface of the cartilage.

Important signs are:

1. Sudden onset and high fever

2. Generalized sepsis 3. High leucocytosis

4. Severe pain on motion of joint

5. Swelling, fluctuation, redness, local

6. Purulent fluid in joint as shown by aspiration

Now there are some low grade infections of the bones and joints which have some characteristics common to the chronic or subacute stage of the acute infections. The most important of these is tuberculosis, sometimes called caries, white swelling.

Tuberculosis of Bones and Joints

Bone tuberculosis is a blood stream infection from a focus usually in the bronchial nodes. possibly also from the intestinal tract. Mild trauma is a predisposing factor, but severe trauma is never followed by tuberculosis. The infection may occur at any time of life but is most frequent between the ages of three and ten. The spine is most commonly affected and next in frequency the hip, knee and ankle, respectivley.

The onset is gradual and usually monarticular. Pain is an early symptom, and is peculiar in that in the hip and shoulder it is referred to a more distant point, as the knee or elbow, while in the distal joints the pain is in the joint involved. Pain causes the patient

to cry out at night during sleep.

Muscular spasm is common in children and less pronounced in adults. There is an elevation of evening temperature but it varies with the joint affected, being higher when the disease is in the ankle than when it is in the spine. The fever is also lower in adults than children.

There is some swelling of the joint, with without apparent increase in synovial There is muscular atrophy on both sides of the affected joint and there is also increased local heat. The tuberculin test is of value in young children.

No bone changes can be demonstrated by X-ray until several months after onset. Bone atrophy is the earliest change noted.

Important diagnostic signs are:

1. Gradual onset

2. Pain on motion of joint involved

3. Muscular spasm

4. Limitation of motion

5. Swelling of joint, moderate

6. Fluctuation usually absent

7. Increased heat about joint

8. Evening fever

9. Disease usually confined to one joint

Low Grade Infectious Arthritis

Low grade infectious arthritis is generally caused by a focal infection in the tonsils, teeth, sinuses, genito-urinary tract or gall bladder. There are two types, one synovial, in which there is proliferation of synovial villi, thickening of capsule and some increase in fluid. The other is the osseous type, in which there may be erosion of the articular surfaces and even actual bone destruction.

This disease is usually confined to one joint and the onset may be sudden or slow, but without severe constitutional symptoms. The

knee is most frequently involved.

In the synovial type there is increased fluid and slight limitation of motion. Pain occurs after excessive or sometimes after normal use of the joint. In this type there is also a condition known as intermittent hydrops in which there is excessive fluid in the joint, remaining a few days and then subsiding.

In the osseous type the pain may be slight or severe and there is some limitation of motion. The swelling is slight. The X-ray may show erosion on the articular surface.

The disease is milder in its course than tuberculosis and continued observation is sometimes necessary before one can be sure of the diagnosis. The Wassermann differentiates it from syphilis.

Important diagnostie signs are:

1. Gradual onset

2. Pain after use of joint

- 3. Motion in joint slightly limited or not at all
- 4. Swelling slight or absent
- 5. Fluetuation usually absent
- 6. Local tenderness slight or absent

Fractures

A few words concerning the diagnosis of fractures.

Not all fractures have the classical signs of erepitus and false point of motion. The diagnosis of some fractures, particularly in children, is impossible without the X-ray. And it goes without saying that every suspected fracture should have an X-ray examination. Incomplete fractures are so common in growing bones that no diagnosis of a joint injury should be considered complete without an X-ray examination.

For example: a girl fifteen years of age was thrown from a horse. The only injury appeared to be a contusion about the right

shoulder. The disability was slight, passive motion free in all directions, active motion somewhat limited by pain. Examined under fluoroscope the bones appeared normal. However, an X-ray film showed an oblique fissure fracture extending from the epiphyseal line downward into the shaft of the humerus. Also there was another fissure fracture in the scapula.

The diagnosis of fracture about the elbow joint in children is difficult by X-ray due to the lack of osseous tissuc. Because of eartifuginous tissue the crepitus is usually soft. Soft crepitus, abnormal motion, and deformity

are signs indicative of fracture.

Fractures of the bodics of the vertebrae are easily missed unless an X-ray is made in two planes. Localized pain and tenderness over the spine, following an injury, should make one suspicious of fracture. Deformity

is frequently absent.

For example: A boy, seventeen years of age was riding in the back seat of an automobile when it collided with another car. The sudden stopping of the car threw him forward but did not throw him from the scat. He complained of pain in the back over the spine. An anterior-posterior film did not show any abnormality, a film taken in the lateral plane showed a compression fracture in the middorsal region

In examining bones by the X-ray for fracture, films should always be made in two planes, first because in one plane there may be no evidence of fracture, and second because one plane may not show the amount of displacement of the fragments. In certain cases stereoscopic films are more satisfactory than

films in two planes.

The fluoroscope should never be used for the diagnosis of fractures except in emergency, in which ease films should be made before instituting treatment. There is always the possibility that the film will be required for legal evidence

FIRST AID IN THE TREATMENT OF FRACTURES

By OTHO C. HUDSON, M.D., HEMPSTEAD, N. Y.

Read before the Second District Branch of the Medical Society of the State of New York, in Garden City, Long Island, on Nov 17, 1932, in a symposium of six papers on "Diseases of the Bones and Joints" presented by Long Island physicians

A^S the most common bone and joint lesion is probably a fracture I am going to use the time at my disposal to emphasize some of the points you already know.

What First-Aid Is: The first-aid treatment of fractures begins immediately following the accident, and must be maintained until the patient has been transported to his home or a hospital and the permanent treatment instituted. The

ambulance of every hospital should be fitted with an emergency fracture outfit consisting of basswood splints, a half-ring Thomas splint for the lower extremity, ring Thomas splint for the upper extremity, and the necessary bandages, slings, sheet cotton, and paper elips for applying emergency traction Without immobilization most fractures of the femur or humerus arrive at the hospital with marked shortening and angula-

tion; but when these same fractures are splinted and transported they arrive at the hospital with little or no shortening and angulation. Adequate first-aid when it is carried out as soon after the injury as possible simplifies the final treatment. Delayed or absence of the initial treatment of the fracture by immobilization often leads to serious complications, delays the permanent reduction, and increases the shock and pain to the patient. In our treatment we must consider the condition of the patient first; and then direct our local treatment of the fracture so as to shorten the period of disability to a minimum and restore function of the part to a maximum.

General Treatment of the Patient: The general condition of the patient must be evaluated. The young robust adult can withstand severe trauma much more easily than the young or elderly patients. In the elderly other complications from pulmonary, cardiac, or renal origin may occur and we must prevent their development if possible. If the patient is unconscious many serious injuries as multiple fractures of the spine, pelvis, or extremities must not be overlooked. The pain of the injury must be relieved by giving morphine sulphate or Majendie's solution hypodermatically immediately. The dose should be large enough to accomplish its purpose. Relieving pain also lessens the associated shock. The shock is treated by protection from exposure, by covering the patient well with blankets, and by bandaging the extremities from the toes to the groin. The extremities from the toes to the groin. medication of value in shock is caffeine sodium benzoate and adrenaline chloride hypodermatically. These drugs may be repeated as necessary.

Examination: The patient must be examined quickly and without increasing his discomfort. All rough manipulation and attempts to elicit crepitus are contraindicated. During examination all unnecessary exposure is avoided. When there is a question of fracture, treat as such until proven otherwise. Gross deformity of an extremity is readily seen. Have some one maintain firm, steady, continuous, and strong traction on any fractured extremity during your examination. If this is done with the extremity in its normal line; your procedures of examination and dressings are made easier. The traction also prevents muscle spasm, relieves pain, and prevents further soft tissue damage. Injuries to the skin as abrasions, lacerations, or protrusion of bony fragments are noted. Nerve injury should be tested for by having the patient move the fingers or toes.

Simple and Compound Fractures: Simple and compound fractures are treated alike except for the wounds present. As every compound fractise potentially infected, no cleaning or debridance be attempted in the first-aid dressing. So or large wounds should be covered with a so dressing after painting the edges of the wo

with tincture of iodine. In doing this begin at the lacerated edge and paint away from it so as not to further contaminate the wound. Under no circumstances should any probing, picking, or attempt at cleaning of the wound be done until the patient is hospitalized and anesthetized.

If large blood vessels are cut, a tourniquet may be needed. When it is applied place it above the knee in the lower extremity and above the elbow in the upper extremity. Use a broad tourniquet instead of a thin narrow one and protect the skin with a towel. The ordinary blood pressure cuff makes a very effective one if distended with air. The tourniquet must not be left on the extremity indefinitely for fear of gangrene in all ready devitalized tissue. It should be loosened from time to time to allow bleeding to occur. Oozing from any wound is best controlled by firm pressure but it is also helpful in cleaning the tissues of foreign materials.

The Fracture Should Be Splinted Not Manipulated: The splintage or local treatment of the fracture varies with the bone involved. During the World War the slogan in fractures was, "Splint'em Where They Lie," and that statement is equally true today in civil practice as on the Splint them immediately. battlefield. itial trauma may have left the bone ends in apposition and we would not want to displace them. Manipulation, if done may displace the fractured fragments, or may cause the sharp bony ends to do considerable damage to the surrounding soft tissues. Certainly every movement of a fracture increases the hemorrhage, swelling, and inflammatory products thrown out by nature. A large blood vessel or nerve may be damaged with disasterous results. A more serious condition is the conversion of a simple fracture into a compound one with manipulation by puncture of the skin thus opening the way for sepsis with its prolonged convalescence or loss of life and limb. When gross deformity is present it may be better to apply the temporary splint in line with the deformity without correction. Do not make any vigorous attempts at reduction until they can be done painlessly as they are not needed in the first dressing.

Requirements of a Splint: The requirements of a good splint are that it is long enough to immobilize the part and that usually requires the immobilize in the immobility of th

e or

stretcher is obtainable, take the door off the hinges and use this to transport the patient.

In fracture of the clavicle, immobilize the arm at the side of the body by means of a bandage

with a towel in the axilla.

In fracture of the humerus, the best immobilization is by means of the Thomas hinged arm splint in which traction from the padded wrist can be maintained by a Spanish windlass. The extremity is slung in the splint by means of slings, and then bandaged to the splint to prevent motion. As one does not usually carry this apparatus in his automobile, the use of an axillary pad of towels and bandaging the arm to the chest with a sling about the wrist and neck is satisfactory.

In fractures of the elbow, it is best to splint them in the position that the patient holds the extremity. If the elbow is extended, use a padded piece of wood from the finger tips to the axilla and bind the arm to it. If the elbow is flexed, the axillary pad and binding to the chest wall is

useful method.

In fractures of the hand, wrist, or bones of the forearm a long padded piece of wood, magazines, or tightly rolled newspapers extending from the finger tips to the mid-arm serve as a good tem-

porary splint.

In any fractures of the femur, or tibia and fibula, the Thomas leg splint is again the ideal method of immobilization. The splint may be quickly applied and traction on the extremity maintained from the ankle. Cutting the trousers leg and folding over the side bars of the splint give excellent slings.

In fractures of the shaft of the femur, tying one lower extremity to its mate affords some immobilization. In fractures about the neck of the femur and intertrochanteric region, the only sure way of holding the position is by using a long splint extending from the axilla to the heel. The best one is probably the old fashioned bedslat padded and bandaged to the extremity. Garden tools with long handles made good splints.

In fractures of the tibia and fibula, and about the ankle, the use of a pillow splint with three boards placed beneath the pillow case (one posterior and one on each side) extending from the toes to the mid-thigh and tied securely about the leg and pinned about the foot to prevent twisting is the quickest splint to make.

In fractures of the patella, a long padded board from the ankle to the groin is all that is needed.

Summary

The important points in first-aid treatment are:

1. Relieve the pain by morphine sulphate hypodermatically.

2. Treat the shock by warm blankets and un-

due exposure.

3. Prevent further injury to the damaged extremity by unnecessary movement.

4. Splint the fracture securely using a splint long enough to produce immobilization of the joint above and below the site of injury.

5. Cover all compound wounds with sterile dressings immediately and swab the skin edges with tincture of iodine. Control severe hemorrhare.

6. Transport the patient to a hospital as quickly as possible where the permanent treatment can be carried out and roentgenograms can be taken.

7. Do not perform painful operations or manipulation until the patient is anesthetized and you are ready to carry out further treatment.

COMMON DISEASES OF THE BONES AND JOINTS IN CHILDREN By WALTER C. A. STEFFEN, M.D., FLUSHING, N. Y.

Read before the Second District Branch of the Medical Society of the State of New York, in Garden City, Long Island, on Nov. 17, 1932, in a symposium of six papers on "Diseases of the Bones and Joints" presented by Long Island physicians.

WHEN one considers diseases of the bones and joints in children, there are certain rather elementary fundamentals with which we are all familiar but which should be constantly borne in mind.

The Growth Factor—The most important factor is involved in the phenomenon of growth. The adult bone and joint is static in this respect. Growth brings with it an extremely active metabolism and a much greater vascularity. The growth centers are either involved in or adjacent to seats of many of the common pathological processes affecting the bones and joints of children. Interference with growth may produce deformity by shortening, even though function may be

otherwise restored. However, the more active metabolic processes of a child also aid in the more rapid restoration of function and allow a far better prognosis than is often possible in a similar condition in an adult.

For reasons perhaps not altogether clear these tissues in children appear to be more vulnerable. The bones and joints are more frequently attacked by acute diseases, and when attacked the destructive process advances rapidly, because the child's defense mechanism is not so well organized, but when the tide turns repair proceeds with greater celerity than in the adult.

Although the osseous and joint system of the child seems to be more susceptible to acute conditions luckily, with a few exceptions, it is spared the chronic forms of arthritis and bone disease.

The Diet Factor—Another factor of the utmost importance in the prevention and treatment of bone and joint diseases in children is intelligent supervision of the diet and accessory factors. Fortunately the empiric era is passing and we are coming to a more scientific basis for our diets. However, much is still unknown and we have to combat a great deal of pseudo-science in dietetics.

The preventive action of orange juice due to its vitamin C content, in scurvy and the almost miraculous cure of the same condition by this agent need only to be mentioned. In addition some recent work seems to show that vitamin C plays a part both in dentition and ossification. In the same category the use of vitamin D or sunshine in rickets is of equal importance.

The diet of the child calculated to build sound bone should be well balanced and furnish abundant mineral salts and vitamins. The best sources of mineral salts are milk and vegetables. Such a diet also furnishes all the necessary vitamins except D. This is best administered in the form of cod liver oil. Viosterol furnishes an ample source of this vitamin but it is not as well utilized as when cod liver oil is given. The combination of viosterol and cod liver oil seems to furnish an optimum way, when large amounts of vitamin D must be administered. Up to the present time I have found a proper diet an adequate source of all the other vitamins and do not feel it necessary to use the various vitamin preparations.

Rickets—The use of sunlight, particularly the ultra-violet radiation, in the therapy and prophylaxis of bone and joint diseases owes much to the orthopedist, who pioneered this form of treatment. Vitamin D internally and ultra-violet radiation, artificial or natural, are in a large measure interchangeable or may be used to supplement one another.

When an infant receives insufficient ultraviolet radiation or an inadequate amount of vitamin D internally, rickets may result. What constitutes a sufficient quantity of these agencies for prophylaxis or treatment is a factor that varies greatly with the individual child. Race and heredity are also etiological factors in the development of rickets.

For the purposes of this discussion the bony pathology of rickets may be summed up briefly as a deranged ossification, manifesting itself in hyperplasia, delay and rarifaction. All these changes may be present at one time. The bones are readily distorted and fractured. The fractures may be multiple.

In the bones of the skull we find the rarifaction resulting in cranio-tabes, also the hyperplasia, at a somewhat later date, giving us the parietal and frontal bosses. It should be mentioned that cranio-tabes is not always a ricketic manifestation. The beading of the ribs, one of the early and easily recognizable evidences of rickets, is known to every one. The later appearing deformity of the lower chest wall resulting in Harrison's groove is of considerable importance for the possible interference with respiration. The deformities of the pelvis may be of grave import in girls.

Probably the commonest orthopedic disabilities arise from the changes that rickets produces in the lower extremities. A good many cases of knock knees and most cases of bow legs are due to rickets. We also find a relaxation of the joints which augments the deformities just mentioned and predisposes to weak and flat feet and the pronation of the feet so often seen in children.

Attention should be called at this point to the importance of the early recognition of these symptoms, the adequate treatment of the ricketic condition by methods already alluded to and the prompt institution of proper orthopedic measures when indicated.

It might be mentioned that in early cases the x-ray will show characteristic changes in the bones before they are manifest clinically.

Scurvy—Although scurvy is becoming a comparatively rare disease it is well to remember that any artificially fed infant who cries when handled and whose joints appear tender and at times swollen should be suspected of having scurvy. When this is associated with hemorrhages into the gums the diagnosis is certain. In any event the therapeutic test of orange juice for a few days or the x-ray finding of the characteristic white line at the diaphyseal end of the long bones will confirm the diagnosis. Occasionally an epiphyseal separation due to hemorrhage may also be found

Rheumatism — Rheumatic fever is not usually considered in the discussion of diseases of the bones and joints, yet because of the errors that often arise in the diagnosis of this condition it seems wise to consider some of the manifestations of rheumatic infection in children. Rheumatic fever is a disease of childhood, not of infancy. It may occur without fever, simply as vague fleeting pains usually in the lower extremities, sometimes in the fingers, the so-called growing pains. A name that had better be discarded. These pains when they occur in the legs may, how-

ever, be due entirely to weak or flat feet. The best known manner of onset is with fever, sometimes a hyperpyrexia. The joint involvement may precede or accompany the elevation of temperature. The involvement in rheumatic fever is always poly-articular in contradistinction to acute arthritis and other conditions to be discussed later. Joints are involved successively and clear up completely upon recovery.

The greater frequency of cardiac involvement in children with rheumatic infection deserves mention, because it necessitates care

long after the joints have subsided.

The treatment of rheumatic infection offers nothing new. Rest and salicylates are still the best therapy. Salicylates apparently relieve the pain and act as anti-pyretics but do not affect the course of the disease.

Arthritis-There is confusion as to the character and nomenclature of chronic arthritis in children. Fortunately this group of diseases is uncommon. One type, an atrophic arthritis is known as Still's Disease. describes the onset of chronic arthritis as sudden with fever and multiple joint involvement, or with persistant fever sometimes for weeks before the joints are affected. In another type the joints may be involved with little or no elevation of temperature. Later the lymph glands and the spleen may be enlarged. The disease frequently begins in children before three years of age, is chronic in its course and often results in joint deformity. McRae2 believes that chronic arthritis in children is a form of arthritis deformans. He is also of the opinion that some adult arthritis deformans may be based on these childhood infections. Chronic arthritis may follow scarlet fever, measles and suppurative processes in the pleura, bones, accessory sinuses, teeth and On the other hand, I have seen arthritis follow scarlet fever a number of times, but complete resolution always occurred and no chronicity was observed.

The treatment of chronic arthritis is symptomatic. Infected foci should be eradicated. The joints require physio-therapy and at times

orthopedic care.

Acute suppurative arthritis and acute osteomyelitis are principally diseases of young children. Both processes are often found associated. The organisms usually recovered are streptococci, pneumococci, staphylococci, or gonococci.

Various modes of onset have been noted. After a pneumonia a septic type of temperature may persist and the involvement of a large joint may be found. The local process develops rapidly and fluctuation often appears

in a few days. Or subsequent to an acute upper respiratory infection, pain and swelling of the knee or another joint appears. The inflammation may also involve the peri-articular structures. Again the disease advances rapidly, so that evidences of suppuration can be detected early. In other cases the onset may be sudden without any apparent previous disease. These cases often have a high temperature. The tenderness and slight swelling are at times overlooked due to the extreme prostration. Pneumonia may be suspected as the cause of the illness. Yet a careful examination will usually reveal a tenderness over one of the long bones or the swelling of a joint. Involvement of the hip presents considerable difficulty from a diagnostic standpoint.

Usually one or a few joints are involved, hip, knee and shoulder in order of frequency, except in gonococcus arthritis, which may be multiplied and often attacks the small joints. In the gonorrheal form the disease is usually less severc. The presence of a vaginitis or an ophthalmia and the fixation test are valuable

aids in diagnosis.

Blood cultures except in the gonococcus infection are often positive.

Osteomyelitis and suppurative arthritis require early surgical intervention. The aspiration of a suspected joint for diagnosis frequently allows earlier interference. The destructive process in these conditions is usually extensive. A fatal issue from septicæmia or meningitis, the latter particularly after pneumoccic infection, is not uncommon.

Care should be taken to differentiate the rarer gonococcus arthritis, as this usually goes on to complete resolution. The use of vaccine in gonococcus infection is advocated.

Acute suppurative disease of the bones and joints differs from rheumatic infection in that it is largely mono-articular, the local signs are greater, and, most important, its principal occurrence is before two years of age. Let it be repeated that rheumatic fever is rare before three years.

In my experience the x-ray has been of little value in the early diagnosis of acute arthritis and osteomyelitis. Later when there is much fluid in the joint or bone destruction has taken place the x-ray findings are characteristic.

Tuberculosis of the bones and joints is essentially an orthopedic problem and will be covered so much more authoritatively in this symposium from that standpoint that I will touch upon the subject but briefly.

It is generally conceded that most of the bone and joint tuberculosis is of bovine origin. The tuberculin testing of cows, the pasteurization of milk and the more careful control of human cases all have played a part in making bone and joint tuberculosis in children a much rarer disease than it was twenty years ago.

In spite of the safeguards thrown around our milk supply, raw milk should not be fed to infants or children, because there is still a possibility of infected milk reaching the public. The milk should be boiled or pasteurized. Parents should be especially cautioned about this when away on vacation or in traveling. Boiled or pasteurized milk will prevent the bovine type of infection and incidentally septic sore throat and diarrheal diseases.

It seems hardly necessary to mention it, but the diagnosis of growing pains is still made in the child with a slight limp and perhaps a slight stiffness of the hip. The physician should be ever on his guard lest he miss those early, slight and often indefinite symptoms of beginning bone and joint tuberculosis and deprive the child of that adequate orthopedic therapy which at this time means so much.

Syphilitic osteo-periostitis is another disease which is becaming rather infrequent. Due no doubt to the active and intensive efforts to prevent and cure the disease in the mother.

As inferred in the previous statement osteoperiostitis is seen in hereditary syphilis. It affets chiefly the long bones and may be associated with an acute epiphysitis, the latter often producing symptoms of a pseudo-paralysis. X-ray and the serum reaction of mother and child are important aids in diagnosis. Time does not permit a discussion of antisyphilitic treatment in infants, but the value of sulpharsphenamine for this purpose because of the relatively safe and easy intramuscular means of administration deserves mention.

The occasional involvement of joints in purpuric diseases and the massive joint hemorrhages in hemophilia can only be brought to mind in a review of this type.

One further condition might be mentioned, namely, the occurrence in serum sickness of a transient polyarthritis simulating a rheumatic infection and at times requiring differentiation from a true arthritis, particularly when it is seen in scarlet fever.

DISEASES OF BONES AND JOINTS—PROCEDURES IN PHYSICAL THERAPY By JEROME WEISS, M.D., BROOKLYN, N. Y.

Read before the Second District Branch of the Medical Society of the State of New York, in Garden City, Long Island, on Nov. 17, 1932, in a symposium of six papers on "Diseases of the Bones and Joints" presented by Long Island physicians.

PHYSICAL therapy in the treatment of diseases of the bones and joints is not new, in fact it probably preceded all other methods of treatment. Exposure of an ailing member to the sun, steeping it in hot or cold water, manipulation of a stiffening joint,—just to mention a few of our "modern" methods which have come down from antiquity.

The object of all physical therapy treatment of a bone or joint is to produce in that part some beneficial change which is difficult to obtain by any other means. Physical measures have their distinct indications, and when these observed and the proper modalities selected and applied, satisfactory results may be expected. The armamentarium of the physical therapist has been greatly broadened in recent years, until now it has assumed rather formidable proportions. Fashions change in physical therapy measures as in other things, certain modalities pass in and out of favor repeatedly, always with reasons which at the time seem quite logical.

In our limited time it will not be possible to present a complete detail of the subject, so I will attempt to describe a few of the out-

standing advantages of physical methods and also some of their contraindications.

In medicine we have altogether too few true specific treatments. In the treatment of tuberculosis of the bones and joints we find a true specific in ultra-violet light. The work of Rollier at Leysin has left no question of the efficacy of the treatment. In rickets ultra-violet light is also a specific either applied directly to the body or obtained second-hand through natural or artificial sources of vitamin D. Many other conditions of the osseous structure respond well to ultra-violet therapy, but specific action is not noted.

Diathermy is another valuable remedial agent which has been developed in recent years. It is particularly adapted to treatment of the bones and joints, but here the method of application and consideration of the indications are of the greatest importance. The response of a Neisserian joint infection to diathermy treatment is, in the opinion of many, another instance of rare specific action. The acute gonorrheal joint is extremely tender, and application of electrodes is difficult. Development of short wave technique, which

requires no application of electrodes, may in the future obviate this difficulty. With our present equipment experience has taught several novel methods of application, particularly the use of saline tubs, which make the treatment possible and effective

In order to treat any part with diathermy the bulk of the current must pass through the Failure to accomplish this will area desired give but poor result, which will usually be ascribed to the modality rather than to its ap The after treatment of fractures with diathermy is familiar to all, and its value is now conceded. In the injured joint with limited motion not due to bone block we can expect much benefit from the use of diathermy Correct and gentle application of the treatment will quickly dispose of extravasated blood and lessen thickening of the joint cap sule which otherwise so often occurs these cases the decongestive action of the static effluve and induced sparks will also be of value

The effect of diathermy is to produce deepseated heat by the passage of a high frequency oscillating current through the tissues temperature attained is rarely sufficiently high to be bactericidal per se But the increased temperature produces an active hyperemia, with all the blood vessels widely distended An increased supply of blood is brought to the parts under treatment, with fresh antibodies, phagocytes and repair materials, and the better to carry away detritus. With the above in mind we can readily note several contraindications to the treatment. Acute infection in a bone will rapidly develop pressure under diathermy treatment unless free drain age is provided. In the case of an arthritic joint where the distant primary infection is still active and the blood stream is loaded with toxins, bringing more blood to the part may only serve to aggravate the condition In an acute pyogenic infection production of an active hyperemia in the immediate area may lead to dissemination and septicemia same is true of a Koch infection of a bone or joint Danger is also apparent in any hemor rhagic condition, where production of active hyperemia is likely to cause further bleeding In the presence of a malignancy there is to be expected increased danger of metastasis if the application of diathermy is attempted

Baking and massage have been extensively used in arthritic and other conditions, too often for want of any better mode of treatment. The results are seldom those desired Despite the extensive use of massage and the great number of operators who apply it, there are few who ever acquire the necessary degree of skill to correctly treat all cases which

may be encountered. Were this not true we could expect far better results than are usually obtained

Cataphoresis or ionization is another modality worthy of mention which has had its The posphases of popularity and disrepute sibilities of the treatment are attractive, but a clear conception of its application and limitations is essential if any benefits are to be expected The majority of the active substances used in cataphoresis treatment to the joints are amons, which necessitates their application to the negative pole as the active one is under the negative pole, the alkali former, that galvanic burns are most likely to occur Moreover, these are particularly likely to occur when a pad of moistened lint is used rather than immersion of the part in a solu tion of the desired material Thus we can readily see that for the best application of cataphoresis we are limited to the distal portion of the extreinities, which are easily treated by immersion in the solution of chronic arthritis of the fingers and toes, and metatarsalgias, so often resistant to medication and other forms of treatment frequently respond in a most gratifying manner to the use of sodium salieylate by cataphoresis Many authorities claim that the benefits derived are brought about only by the galvanic current used, and that the ionic medication plays no part They point out that the ions move very slowly, and cannot penetrate deep layers of tissue in the time allotted to each treatment Moreover, the active circulation of the blood will carry away the molecule or atom which appears when the ion gives up its specific electrical charge All of these objections lose part of their significance when the distal ends of the extremities are considered, which possibly is another factor in the successful treatment of these parts by the

Manipulation of a diseased bone or joint must be carried out with the greatest caution Pathological fractures have resulted from the slightest stress applied where rest was indi-In the stiffened joint following injury or disease a gratifying immediate result can be obtained by forcible manipulation under anesthesia But too often the period of unprovement is brief. In breaking up of the organized tissues homorrhage has occurred, much blood is extravasated, and more massive organization than before is the result In many of these cases persistent use of diathermy would produce far better end results without any manipulation whatever

Other Measures—In the treatment of certain beingn and malignant tumors of the

bones x-ray and radium play an important part, but these methods are not usually included in the general classification of physical

therapy.

In closing we must not omit reference to hydrotherapy and its allied forms of treatment, such as the mud bath, paraffin bath, and hot air bath or blast. Occasionally these are combined with one or more of the modalities previously mentioned, often with the most desirable results.

Physical therapy has greatly added to the successful treatment of diseases of the bones and joints, and we can look forward to still further development along the lines described and possibly others as yet unthought of.

THE TREATMENT OF CHRONIC MULTIPLE ARTHRITIS

By GEORGE E. ANDERSON, M.D., BROOKLYN, N. Y.

Read before the Second District Branch of the Medical Society of the State of New York, in Garden City, Long Island, on Nov. 17, 1932, in a symposium of six papers on "Diseases of the Bones and Joints" presented by Long Island physicians.

As in all chronic disease processes, the etiology of which is obscure, the therapy of chronic multiple arthritis is far from resting on a completely sound basis. Until we fully understand not merely the pathological anatomy of this protean group of diseases but, more important, the exact mechanism of physiology involved in its production, we shall be obliged to grope in darkness for adequate therapy. At present we designate one phase of the disease with its pannus, cartilage destruction, muscle atrophy, ultimate joint annihilation, and deformity as "atrophic" and on the basis of presumptive evidence call it "infectious" in origin.

The far less virulent disease occurring more usually in senescence and presenting a different joint picture of fibrillary degeneration of cartilage leaving eburnated bald areas of joint surface and bony overgrowth at joint margins without any tendency to ankylosis, we call "hypertrophic" and arbitrarily relegate it to "degeneration." In truth we are in the same controvertible position as our clinical predecessors when they classified nephritis—a beautiful anatomical classification

unyielding to physiological proof.

No one will deny that infection, restricted capillary beds, faulty metabolism, and degeneration all play important parts, but the stumbling block is "how and why?" We do not know the mechanism—our large array of treatments attests to this fact. One patient is virtually torn asunder in the search for focal infection; another is subjected to the metabolism expert who may deplete him from the standpoint of calories, carbohydrates, proteins, or purins, emphasize vitamine deficiency, alkaline-ash diet, or uncover food allergy; the physio-therapeutist ranges his wares from elaborate electrical therapy to needle baths, colonics and body massage; the endocrinologist finds therapy in substitutional methods; the immunologist delves into specific vaccine methods or non-specific protein-shock therapy; the allergist pushes desensitization to bacterial proteins, toxins, and filtrates; and so ad infinitum.

All these principles have their important

places and with selection are justifiable—the real disease, after all, will usually remain, possibly improved, possibly made worse. A natural remission will often be heralded as the remarkable result of a specific therapy. Actually, there is no "cure-When one reports a large percentage of cures, he has under scrutiny not the same disease but usually an acute or subacute arthritis which is so commonly self-limited with proper methods of physiological rest. In the present state of our knowledge the only specific is individualization of the case in question—therapy must of needs be by induction—we have as yet no great truth from which to deduce rational treatment. The clinician who treats one disease entity in all patients must surely fail. With selective therapy, studying the patient as a whole, we may expect clinical improvement in about 50% of atrophic cases and 75% of hypertrophics. The rest will be unimproved and in a small percentage obviously made worse.

Types of Cases: Let us consider typical problems. We are presented with the obese plethoric female of the climacteric who complains of pain limited to the knees and objectively shows crepitating exostosed knee-joints without muscle atrophy or tendency to ankylosis-in addition, weak feet and Heberden's nodes. Aside from her local disability, the patient has no complaints In common terminology her disease is classified as "degenerative arthritis." She is a problem for both the orthopedist and the internist. The former's function is to build up the feet through support and selective exercises so that weight-bearing on the affected joint surfaces of the knee is equally distributed. The internist will also play a part in minimizing trauma to the knees and feet by reducing weight by rational diet which includes adequate protein, calcium and vitamine content but emphasizes low caloric ingestion. He must know whether this patient's cardio-vascular system will make restriction hazardous and accordingly regulate carbohydrate. He will probably expose the patient to generalized body massage for improvement of peripheral circulation

He may use dessicated thyroid to stir iip a sluggish patient. Strange as it seems in this type of case, stock streptococcus vaccine subcutaneously at weekly intervals frequently helps these patients—probably through non-specific protein effect.

In contradistinction to this patient, let us visualize the true chronic atrophic arthritic-a sallow, frequently poorly nourished individual with rapid pulse, low blood pressure, cold clammy hands, fusiform finger-joints, cold dusky lower extremities, appearance of anemia usually out of proportion to its actual degree (because of unfilled peripheral capillary beds) This patient is ill and should obviously not be depleted by restricted diet but rather coddled as one would a tuberculous case Most dramatic is often the improvement of such a patient when a previous regimen of caloric, protein, or purin starvation is supplanted by a well rounded-out adequate diet Nor would one in such a patient be inclined to "rip out" even obvious focal infection without considerable rejuctance Probably most of the real damage from the primary focal infection in question has long since been done, secondary foci having been established and the patient already been completely sensitized by repeated insults over months or years If the suspected focus is actually the guilty one, the immediate extirpation in such a patient may prove as disastrous as would an excessive dose of a highly specific vaccineprecipitating the patient on a downward course

Vaccines Let us assume as is generally accepted and on good evidence that infection with the streptococcus in one of its many families is responsible for this patient's disease and that infection has entered through diseased tonsils as a It is the practice in the Arthritis Clinic of The Brooklyn Hospital to treat such patients with a preliminary course of autogenous vaccine made from the tonsils in question-in accordance with the technique recommended by Dr Reginald Burbank 1 On theoretical grounds, we search for other points which may harbor streptococci, especially stools, gingivae, nasal passages, prostate, chronic discharging ears, gall bladder bile Streptococci found are incorporated into the vaccine, which is injected subcutaneously at weekly inter-Initial doses are very minute, occasionally as low as 100,000 organisms, increasing cautiously, aiming all the while to keep within the dose of tolerance as evidenced by absence of systemic reactions, failing blood pressure, or marked focal reactions in the joints. Recently we have used the intradernial route in view of the concept of the role of the reticulo endothelial system in mmunity reactions. We believe the latter route has definite advantages but are not prepared at this time to give relative statistics

Having carried on such therapy for three or more months we review the case from the stand point of tonsillectomy, performing the latter only

when the patient begins to show evidence of general physical betterment as increased blood pressure and subjective improvement. Tonsilections seems then in order, and in our experience is much less fraught with danger of harmful reaction.

We do not consider abscessed teeth in the same category with diseased tonsils but practice early removal, one or two at a time. Several considerations make this seem feasible. 1—the tonsils and lymphatic ring are frequently fed infection from diseased teeth. 2—Autogenous vaccine has little beneficial effect when administered in the present locked up infection. The teeth represent locked up infection from a drainage stand-point—the tonsils are more susceptible of untural free drainage. 3—The tooth root may furnish us with organisms of value for vaccination. 4—Extraction piecemeal rarely produces undesirable reactions.

Such vaccine therapy is continued with gradnally increased doses—usually in increments of one to five million organisms until maximum and stationary improvement is obtained as evidenced by absence of further progress over a six or eight month period. This final stage may be one with out symptoms but more often is one of definite amelioration of symptoms, rather than "cure"

All patients who are to receive any autogenous vaccine treatment go through a preliminary bac teriological study and in addition have their native serum complement titrated in a hemolytic sys-It is thought that low titres contraindicate vaccine therapy We no longer carry through routine complement fixation tests against fixed streptococcus^a antigens as originally recoinmended by Dr Burbank considering that the results of these while showing the presence of immune bodies developed in response to infection, do not posit the time when such infection was active One has no means of stating that the im mune response did not occur to an infection long since mactive or irrelevant. Most any normal individual has at some period of his life been ob liged to develop antibodies against the strepto coccus. It is interesting to note that cases termed as infectious frequently have a long list of positive complement fixations in high dilution to a variety of streptococci Presumably all of these streptococci are not simultaneously active. Such reactions may represent sensitivity to the strepto coccus in a "group" sense rather than strain-specificity Certainly, they help to malign the streptococcus as playing a part in this disease The maze of steps between focal infection with streptococcus and joint pathology is liowever, still unravelled. The mere casual finding of a streptococcus in the blood stream or joint is not necessarily significant of a local infectious process in the joint Transient bacternemia may occur even in normal individuals and may be the very means by which protective antibodies are estab

lished. The entrance of such organisms into the blood stream would form a classical means of sensitizing the host from an allergic standpoint to the bacterial proteins and toxins. Such hypersusceptibility might be expressed in various ways from vasomotor rhinitis, hives and asthma to a far less obvious influence on the capillary beds and synovial membranes of joints. Freiberg⁴ has experimentally produced in rabbits typical human atrophic arthritis by establishing hypersusceptibility to bacterial filtrates alone.

The extreme sensitivity of a few of our pa-

to leg-length of patient.

tients to vaccine and bacterial products tempts one to consider an allergic side to the disease. Several of them developed asthma and hives together with increased joint manifestations coincidental with autogenous vaccine injections. In such patients we can reproduce this syndrome at will. The sharp flare-up and defervescence of their joints is somewhat analogous to the joint response to a heterologous serum. The caution with which a truly specific vaccine must be administered to avoid marked focal manifestations in joints is quite analogous to the focal response of an asthmatic to an excessive dose of pollen-

antigen. In man, the injection of an overdose of autogenous vaccine sufficient to produce systemic reaction is accompanied by a diminution of blood complement. Friedberger and Hartock have shown that in animals with the occurrence of anaphylactic symptoms there is also a reduction of complement.

Allergy: Experimental work of others in relation to allergy in arthritis led us to skin-test our patients to their vaccines. The results were very disappointing. We inconsistently obtained positive skin-tests immediate or delayed. Recently, Doctors Arthur Lamb and Louis Nerb of The Brooklyn Hospital have been making observations on these same patients with bacterial filtrates—using some fourteen virulent strains of streptococci Patients originally negative on skin-test to their own vaccine and who did not respond to vaccine therapy were skin-tested to the filtrate. A number of these showed strongly positive reactions both in skin⁵ and locally in joints. When treated intradermally by graded doses of the filtrate, not only did the skin-tests become less marked but joint symptoms improved. Encouraged by their findings, they have been applying autogenous filtrates in a similar manner. We hope for larger favorable response than to autogenous vaccine, which in our experience is extremely limited in its application. The filtrate should present a more effective therapy by desensitizing the patient to the bacterial products rather than to the organisms themselves.

General Treatment: Whatever be the argument for or against vaccine and filtrates, we may not forget that the host is a patient with a general systemic disease of which the joints are but one Failure to consider secondary manifestation. anemia, low blood pressure, malnutrition, faulty bowel function, and the mental depressive state so characteristic of most of these sufferers, may When possible, preclude satisfactory results. systematic general body massage should be practised for its tonic effect on peripheral circulation Contrast baths to hands and legs are helpful-the glove bath which I have recently seen described gives symptomatic relief to painful fingerjoints. Elaborate physiotherapeutic apparatus is rarely necessary. It may be interesting to note here that the use of diathermia in our group was disappointing.

In the atrophic type with radiolucent bones, one may find calcium and viosterol of value. In this connection, it is well to adjust diet and to avoid fruits and vegetables of high oxalic acid content (as strawberries and tomatoes) because of the drain on body calcium in the excretion of

It is unwise to keep these patients in bed for any length of time, a week or two being the maximum during any acute exacerbation. Time spent in explaining the necessity for maintaining straight knee-joints by avoiding pillows under

the knees may mean the difference between an ambiliatory and a chair-ridden future (in atrophic

cases)

Muscle atrophy in this disease should be vig orously fought by massage and judicious exercise. In this connection, of considerable help is the "walking chair," ⁶ (Figure 1) whereby a patient may make use of thigh and leg muscles to get about, at the same time obviating the trauma of body weight on pathological knee-joints

To summarize Chronic multiple arthritis is a protean group of diseases, the etiology of which is still obscure Principally for this reason, treatment is uncertain and frequently empiric disease does not readily lend itself to "cure," but by individualization of the patient a majority of these sufferers are considerably helped. The hypertrophic type of the disease is less virulent and yields more easily to therapy than does the

atropluc form Indiscriminate eradication of focal infection is meddlesome therapy and is frequently more damaging than constructive moval of obvious gross focal infection should when possible be preceded by preliminary desensitization with autogenous vaccine therapy is not a "cure all" but merely one weapon in selective cases. It may do more harm than good if injudiciously applied From the stand point of therapy, the allergic concept of the disease with joint pathology an expression of hypersusceptibility to bacterial products bears more promise than does the theory of localized infection in involved joints The finding of organisms in the joints or blood stream does not vitiate the theory of the allergic mechanism. The ultimate treatment is a challenge to the laboratory researcher, to the internist, and to physicians gen erally

POLYCYTHEMIA VERA

Report of Ten Cases Treated With Phenylhydrazine

By KENNETH R McALPIN, M D, and KATHARINE S EDSALL, B S, NEW YORK, N Y

From the Department of Medicine College of Physicians and Surgeons Columbia University, and the Presbyterian Hospital New York City

POLYCYTHEMIA VERA (Erythremia, Splenoinegalic polycythemia, Vaquez's Disease, Osler's disease), is a chronic disease characterized by an increase in the number of the red blood cells. The spleen is usually enlarged, sometimes tremendously Minot says the disease is a new growth of the red blood cells.

The ctiology is unknown. The onset is extremely gradual, and the condition may go innoted for years. There is no known cure, but the progress of the disease is so slow that death is often due to other causes. Patients frequently reach an advanced age. They are poor surgical risks and have but little resistance to any infection.

In 1918 Eppinger and Kloss¹ first treated erythremia with phenylhydrazine Seven years later, in this country, Owen² followed their comple and was enthusiastic about his results Brown and Giffin⁴, Altnow and Carey⁵, Stealy⁶ and Cabot² were among those to report cases benefited by the drug In 1927 Bryan⁵ reported unsatisfactory results in one case and two years later Giffin and Conner⁶ called attention to the danger of giving the

driig to those who were bed-ridden, over 60 years old, who suffered from arteriosclerosis or gave "evidence of advanced visceral injury"

McNamara and Sansum¹¹ reported a case of poisoning from phenyllydrazine in a woman who had been given large doses by an osteo path. This case is particularly interesting because in all probability the patient did not have the disease

Harrop's article is a very comprehensive survey of the whole subject of polycythemia. He discusses the effect of the drug, but does not think there is any definite proof that a normal liver is injured by its continuous use. Owen feared this, as have other observers. Cirrhosis is of course a not unusual complication of erythremia.

In treating such a slowly progressing disease as this, is it justifiable to use such a dangerous drug? Is the benefit sufficient and improvement enduring enough to warrant the risk. After studying ten cases in the Presby terian Hospital and Vanderbilt Clinic, we think that the drug is indicated and to some patients may offer at least as much as any other form of therapy

N. Y. State J. M.

September 1, 1933

Certain individuals are undoubtedly susceptible and respond readily to small doses. So all patients should be watched very carefully when the drug is first given. We usually give 0.1 grams of phenylhydrazine hydrochloride in capsules by mouth, as a starting dose. In patients with only a moderate increase in red cells and hæmogloben, a satisfactory drop in the red cells may be obtained by only one or two capsules a week. In the more severe cases, 0.2 grams may with safety be given daily for five days. After five days, it is well to wait for two or three days to avoid the possibility of an accumulative effect. schedule should be repeated at least twice before increasing the amount. A slight drop in red cells and hæmoglobin may be regarded as a good sign and the same regime continued as long as results are favorable. A sudden drop in red cells contraindicates the drug, for at least a week.

Jaundice is not only an annoying symptom, but may be a danger signal. Hurwitz and Leviten¹² say it is easily avoided but in this series it appeared in four out of ten patients and in only one of these was the patient receiving large doses. Jaundice certainly indicates excessive dosage and should be regarded as a warning in future therapy, if the red cells and hæmoglobin again return to above normal.

There is sometimes a great increase in the number of white cells. Owen³ was very much interested in this and thought it might reveal the tolerance of the individual for the drug. Our patient No. 10 (who without our knowledge was given large doses of the drug when the red cells were going down), did have a leucocytosis of 52,000. In this instance, the rise in white cells undoubtedly was significant and was probably due to the drug, but it is well to remember that in the late stages of erythremia not only leucocytosis, but the picture of myeloid leukemia may appear, even without therapy. (Harrop¹⁰, Minot and Buchman¹³, Klumpp and Hertig¹⁵, McAlpin¹⁴.)

As far as possible and practical, the blood counts were done by the same observer. The Sahli Hæmoglobinometer (16 mg. Hæmoglobin=100 per cent) was used. The pipettes and counting chambers were all standardized. Two pipettes and two counting chambers were used for counting the red cells.

The accurate estimation of hæmoglobin has long been a bugbear for the clinician. We readily admit that the perfect method has yet to appear. At the same time, we believe that with reasonable care the Sahli gives excellent results. Absolute accuracy may not be possible, but with a trained observer working with the same instruments under the same

conditions, the variable element will be reduced to a minimum, and the final results will be more satisfactory than those obtained by the most skillful technicians all using different instruments, be they ever so delicate.

Case No. 1. C. B. No. 84433. An American woman of 47 years. In 1926 this patient had her gall bladder drained, the result was satisfactory for over two years. Then in July, 1929, after more trouble, she had her gall bladder removed, and made an uneventful recovery. Nine months after the second operation (April 25, 1930), she came in complaining of fatigue, backache and some dizziness. Spleen was palpable 6 c.m. below the costal margin. Blood count was as follows: hæmoglobin 138 per cent; red blood cells 7,800,000; white blood cells, 9,000; neutrophiles 70.5 per cent; cosinophiles 3 per cent; basophiles 2.5 per cent; lymphocytes 22:5 per cent; monocytes 1.5 per cent; platelets 675,000. (See Chart I).

There was nothing in her history to suggest polycythemia vera before this, but with such a blood picture and large spleen we made the diagnosis. She was given 0.1 gm. phenylhydrazine twice a day for five days, allowed a two-day rest, then the same dose was repeated for two days and she was allowed a five-day rest. After this little course of treatment (1.4 grams in two weeks), she became slightly jaundiced for four or five days. As the red cells had come down to 5,000,000 and the hamoglobin to 100 per cent, the drug was stopped for two months, then begun again, but in very small amounts.

nionths, then begun again, but in very small amounts.

At present she is able to do her secretarial work without difficulty and has few complaints. She takes 0.1 grams of the drug every week or two and seems better for it.

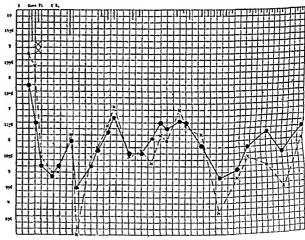

CHART I. CASE No. 1. C. B. See Explanation, page 1045.

Case No. 2. H. Z. No. 219974. A Jew of 22 with a schizoid personality. He complained of pains in joints and ringing in his ears. His face was red but this was partly due to recent exposure to the sun. He did not look ill. The spleen was felt at the costal margin; hæmoglobin was 108 per cent, with 5,500,000 red blood cells. With these findings, a diagnosis of polycythemia

vera in its early stages appeared justified.

He had had two small courses of phenylhydrazine (0.3 grams in three days, then 1.0 gram in two weeks), which had a marked effect on his blood count. The hæmoglobin dropped to 68 per cent and red cells to 3,000,000 in two weeks. Both returned to normal in another fortnight. There was some jaundice for a few days when red cells were down. His complaints remain unchanged.

Because of his peculiar personality, he was a most unsatisfactory person to deal with and is almost a psychiatric problem. Usually we do not treat patients with so moderate an increase in hæmoglobin and red eells; we did so in this instance because of the multiplicity of complaints. Although he received in all only 1.3 gm. of drug in three weeks, it was too much.

Case No. 3. H. K. No. 79946. March 4, 1929. A Jew of 44 came in because of dizziness for two years. His spleen was not felt, but a diagnosis was made from the blood count. Hamoglobin 120 per cent; red blood cells 6,800,000; white blood cells 14,500; neutrophiles 5 per cent; eosinophiles 1 per cent; monocytes 4.5 per cent; lymphocytes 3.4.5 per cent; monocytes 4.5 per cent; unclassified 1.5 per eent; platelets 190,000.

He was given 0.6 grams phenylhydrazine within three

days with no effect.

While in the hospital he developed a sub-acute Glaucoma and was considerably helped by operation (simple iridectomy).

Since then his count has varied little, and he has been given no more phenythydrazine. His spleen has never

been felt and his platelets have remained low.

The last blood count was: haemoglobin 120 per cent; red blood cells, 5,900,000; platelets 190,000. He holds his weight; is happy and active. So here is a patient who after two and a half years gets along very nicely without the drug. Under these circumstances, we doubt the advisability of phenylhydrazine. Should he have symptoms, we would consider the drug indicated.

Case No. 4. L. H. No. 275805. A woman of 59 who had been treated for polycythemia for three years. She had complained of severe headaches, vertigo, loss of memory and transient motor nerve weakness. She had been treated with radiotherapy, phenylhydrazine and nu-

merous blood lettings, with some benefit.

On admission in December 1930 her face and mucous membrancs were congested and spicen was felt 5 c.m. below the costal margin. Her blood count showed: hæmoglobin 102 per cent; red blood cells 7,300,000; white blood cells 12,300; platelets 930,000; neutrophiles 89 per cent; eosinophiles 1 per cent; basophiles 1 per cent; bymploet to 7 per cent; monocytes 1 per cent; unclassified 1 per cent.

Although blood pressure, urine and blood urea were normal, renal function test (phenolsulphonephthalein) showed an exerction of only 30 per cent, so it is safe to say that damaged kidneys might account for some of

the numerous symptoms

The blood responded fairly well to phenylliydrazine but the reduction in red cells was not accompanied by a similar improvement in symptoms, and it was thought best to discontinue the drug, especially as the color in-

dex was getting alarmingly low.

The patient complained that her headaches and pains in the extremities were so severe at times as to be almost unbearable and sedatives were necessary. The platelets have always been abnormally high and we think this may have a bearing on her numerous symptoms. Physio-therapy, in the shape of electricity, was tried, and afforded some relief.

With the relative anæmia and possibility of nephritis, the prognosis is, of course, very dubious and the possible benefit from phenylhydrazine questionable.

Case No. 5. M. E. No. 268890. A Jewish man of 59 who was told four years ago that he had polycythemia. He also had arteriosclerosis diabetes mellitus cardiac hypertrophy and insufficiency

When first seen (September 10, 1930) he was not acutely ill but his face was very red and the edge of spleen was felt 17 c.m. helow costal margin; hæmoglobin was 128 per cent and red cells 6,700,000. He had four short courses of phenylhydrazine, the first 0.1 gram daily for five days, and the last three 0.1 gram daily for two

days (a total of 1,1 grains). His hæmoglobin went down to 107 per cent and his red eclls to 5,900,000 and he felt better.

He continued to feel well and had no more plienylhydrazine. Because of his numerous ailments, it seemed wiser not to give him any more of the drug. He was being cared for in the diabetic clinic.

Case No. 6. I. B. No. 296983. In 1922 a Jewish exbartender came to this clinie, complaining of pain around the heart for seven weeks. The pain usually lasted a few minutes and was never excruciating, nor was he alarmed by it.

His face and mueous membrane were eongested, but he did not appear acutely ill. The heart was enlarged, but otherwise appeared to be normal. The spleen reached Blood Wassermann and uring were negative.

Blood count; hæmoglobin 140 per cent; red blood cells 6,300,000; white blood cells 7,900; platelets 440,000; differential not significant.

X-ray showed heart enlarged and electrocardiogram was "yery suggestive of myocardial damage."

A diagnosis of polycythemia vera was made and the possibility of coronary selerosis was considered. He was given radiotherapy, a single exposure covering half of anterior, or posterior aspect of the trunk, or the long bones. In nine months he was treated fifteen times, The hæmoglobin dropped to 84 per cent and red cells to 3,300,000.

He gained weight and the attacks of pain were less severe. In addition to radiotherapy he was also given nitrites.

His visits were not regular, but in October 1926 (four years after first visit) he was admitted to the ward with some pain in left upper quadrant of abdomen, which was thought to be due to splenic infaret. Pain lasted only a few days and he left the hospital much better.

After an absence of one year (i.e., five years after first visit), he reappeared with pain in the back and bloody urine. This was followed in a few months by an attack of phlebitis in left lcg.

In April 1929 his hiemoglobin was 132 per cent, red cells 9,700,000, and white blood cells 13,000. He was given three short courses of phenylhydrazine, after which the hæmoglobin dropped to 100 per cent. he did not like the drug and we did not urge him to take it. When last seen in June, 1931 (nine years after first visit) he had no complaints, spleen was 12 c.m. below costal margin and hæmoglobin was 121 per eent, red blood cells 9,800,000.

Here is a man who can get along pretty well and al-though his red cells and hemoglobin are far too high, he had no symptoms referable to polycythemia and so we stopped giving him the drug. The explanation of the cardiac pain remains in doubt, although apparently better, the possibility of a damaged myocardium remains.

It is interesting to speculate on the possible relationship between the cardiac pain and the abnormal blood. There is, of course, no gainsaying the evidence of the electrocardiogram but the observations in 1926 and 1930 both show definite improvement over the first taken in 1922. But at the time of these observations the hemo-clobin was between 120 and 125, while the red cells were between 8,000,000 and 8,500,000. Now, to add to the confusion, the red cells were not so high when he was having his pain. It is quite possible that the damage to the licart was not great and the pain was part of the discomfort so usual with these patients. It is worthy of note that one of Owen's patients complained of cardiac pain,

Case No. 7. R. W. No. 83446. In May 1929 a Russtan Jewess of 60 years came into the hospital with a great many complaints. Among the most annoying were headache, dizziness, and pain around the heart. The last was not severe enough to cause her much concern.

She had been feeling bad for three years but thought that her face had been noticeably red for five years. Her blood pressure had been high for approximately the

same length of time.

When first seen by us, the patient was an elderly woman with red face and purplish mucous membrane, not particularly uncomfortable and certainly not acutely ill. The most important finding on physical examination, at least from our standpoint, was a spleen just palpable at the costal margin. The blood pressure was 165/85. Hæmoglobin 160 per cent; red blood cells 8,500,000; white blood cells 14,700; nothing abnormal seen in the smear. The blood Wassermann was positive, Kahn—4. Kidney function test showed excretion to be only 50 per cent. Seven urinalyses revealed neither sugar, albumin nor casts.

Electrocardiographic report was as follows: "The low voltage in all leads indicates a moderate degree of myo-

cardial fibrosis."

X-rays of knees and right foot showed "mild arthritic

changes."

She complained bitterly of headache and was helped but little by sedatives, nitrites or phlebotomy (500 mils). The last had only slight effect on the red blood cells and hæmoglobin.

Splenic extract (83 grams in thirteen days) also proved futile. Her complaints continued to be numerous and varied. The problem was all the more difficult because in addition to being neurotic, the woman was really ill.

The advanced age, hypertension, myocarditis and possible renal involvement made her anything but a desirable patient for phenylhydrazine. However, we decided to try small doses and she was given 0.5 grams in five days, with little change in the blood pieture and no untoward symptoms.

After a visit of two months, she left the hospital slightly improved, to be cared for in the Clinic. Here she was treated for syphilis, her blood Wassermann became normal and for a time at least she was better. This improvement was not lasting and she was readmitted with the same old story on October 27, 1931.

Her condition was practically unchanged, except that blood pressure was up a little (208/100). No change in size of the spleen. The various therapeutic measures had improved the blood pieture but little. Hæmoglobin 140 per eent; red blood eells 7,700,000; white blood eells 11,700.

Two phlebotomies gave little relief and phenylhydrazine was tried again (1.2 grams in sixteen days). Two days after the last dos was 131 per eent and red eells were inical improvement was negligible, but the decrease in red cells continued and in a month the hæmoglobin was 102 per cent

and red eells 5,300,000.

This is a good example of a patient with polyeythemia vera for whom therapy offers little. In addition to the erythremia the patient had definite cardiovaseular disease, some renal involvement and chronic multiple arthritis. Her heart pain did not appear to trouble her much. Splenic extract and phlebotomy did little good. Not at all the type of case we would choose for phenylhydrazine, but the last blood count showed a favorable change and seemed to indicate that the drug was the most effective of any of the therapeutic measures tried.

Case No. 8. M. W. G. No. 224387. A well nourished, heavily built man of 47, with congested skin and mucous membrane. He eame to the hospital first in October, 1929, complaining of headaehes, dizziness and pains in his back, the last so severe that he could not work. His spleen was felt three or four e.m. below the costal margin. Blood count: hæmoglobin 160 per cent; red blood cells 10,600,000; white blood cells 9,800; neutrophiles 77 per cent; lymphocytes 23 per cent; platelets 327,000.

His first symptoms were noticed twelve years prior to admission. He had been treated at different places with radio-therapy and drugs (probably phenylhydrazine) but treatment had been neither regular nor helpful.

He had taken phenylhydrazine for over two and a half years and his blood observed regularly. (See Chart II.) He held his weight, complained of very little discomfort and was able to work steadily.

eomfort and was able to work steadily.

Six months ago (May 7, 1931) he suddenly became very yellow. After receiving 1.7 grams of phenylhydra-

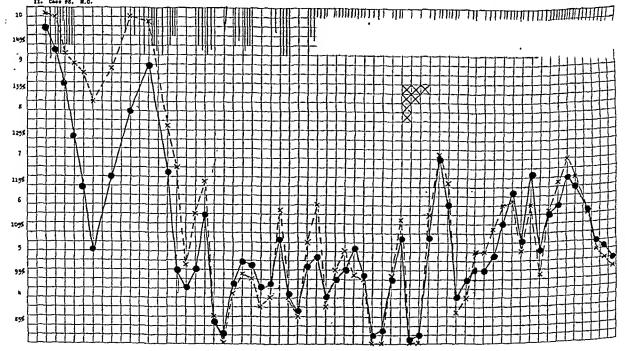

CHART II. CASE No. 8. M. W. G. Sec Explanation, page 1045.

zine in two weeks (09 grams in week immediately pre ceding attack plus 08 grams during week before that) It is interesting to observe that the red cells had tend ed to go up just before he became jaundiced and the dose was mereased from 08 to 09 grams a week For one who had been as resistant to the drug as this man this was not a large dose, he had taken more in a simi lar period. We are inclined to think this was an accu mulative effect and try to guard against it by giving the drug in relatively larger doses over a shorter time, with several days between For example the patient sible, after the 'rest days' The patient is seen, if pos This man of control of the patient is seen, if pos takes his capsules for three or four days and then is allowed three 'rest days' The patient is seen, if pos

This man at present shows no ill effects of what may be considered rather strenuous treatment, and a glance at Chart II will show that the red cells are kept in reasonable limits with less of the drug than was for

merly necessary

Case No 9 R F F No 230091 A college profes sor of 46 years who had been unable to "carry on" be cause of his numerous cerebral symptoms

In 1918 his first blood count showed a hæmoglobin of 115 per cent, with 5,900 000 red blood cells. This was considered a 'slight polycythemia rubra' but no treat ment was given

Disturbing symptoms began in June, 1923 Since that time he has had vertigo, transient paræsthesia, muscle aches, pun in joints, diplople, aphasia amnesia and fre quent nosebleeds. In 1924 he felt so badly that he again consulted a physician who found 12,000,000 red blood cells

He has been treated extensively, both in this country Phenylhy drazine was given first but in So used it had little effect. He was also and abroad bled and given radiotherapy, philebotom, usually afford ing immediate but only temporary relief and radio therapy little if any He also spent about a week in an oxygen chamber without benefit He was first seen at Presbyterian Hospital in October, 1929 At that time his spleen was felt 8 cm be

low the costal margin Radiotherapy was tried again and in eight months the long bones were treated twenty

eight times, without much success. He was then started on phenylhydrazine, and his been taking it pretty regu larly ever since (See Chart III) An endeavor has been made to make him comfortable, rather than keep red cells within normal limits. His symptoms are much less marked and he can lead a more nearly normal life When he is taking more strennous exercise he seems to need more of the drug but feels better, none the less

We think he illustrates the fact that phenythydrazine may be helpful when the Roentgen ray fails How long we can help is, of course problematical, but he cer talmly is better when taking the drug Like patient No 8, he requires less of the drug than he formerly

Case No 10 S A No 238861 On September 11, 1931, a Turkish man of 57 came in because his feet were painful and swollen. He had noticed that his face was red for four or five years. Physical examination showed the liver edge easily pulpable four em below the costal margin. The spleen was felt as a freely movable rounded mass, extending six cm into the right upper quadrant Blood count was hemoglobin 125 per cent red cells 8 500,000, white cells 15 900, neutrophiles 88 per cent, cosmophiles 3 per cent, lymphocytes 9 per cent A diagnosis of polycythemia was made and he was ad mitted to the hospital

He received 35 grams of plienyllis drazine over a perlod of nineteen days. His blood count was followed carefully, but unfortunitely, no allowance was made for a cumilitive effect and four days after the drug was discontinued, his hemoglobin went down to 43 per cent, with 2 400,000 red ecils (October 12, 1931) The white cells were up to \$2000 and reticulocytes were 172 per cent. He was markedly jaundiced

This shows what can happen when the patient's toleration for phenylliydrazine is unknown and an overdose is given. However, in this instance no harm was done, the patient returned for "follow up two weeks after discharge. His hæmoglobin then was 85 per cent red eells 5,100 000, white cells 19 000 He said he had not

felt better for years

On December 12 1931 hæmoglobin was 116 per cent ntd red cells were 6 300 000 He was given 06 of

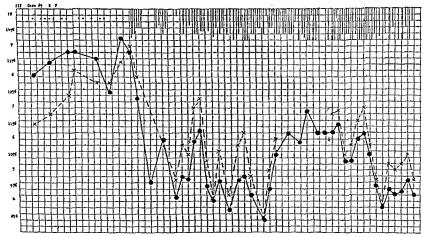

CHART III CASE NO 9 See Extlaration tage 1045

phenylhydrazine in one week which brought the hæmoglobin down to 86 per cent and erythrocytes to 4,800,000. Again he was slightly jaundiced. The color lasted for about two weeks. On January 13, 1932, the

hæmoglobin was 95 per cent and the red cells were 4,400,000; no other ill effects were noted.

Evidently this man must be very susceptible to the

drug, and may do well with smaller doses.

The primary object of this paper is to call attention to the use of phenylhydrazine in treating erythremia. No claim of originality is made; rather is the work of others confirmed. Several of the cases studied have been followed for years and two have received the drug almost continously, one for two and one for two and a half years (Patients No. 9 and No. 8). For the sake of brevity, the histories have been cut down as much as possible. There are, however, a few details worthy of special mention.

The first two patients (No. 1 and No. 2) may be classified as early. Both of these patients became jaundiced after comparatively small doses of the drug. Mrs. C. B. (No. 1) is apparently helped by small doses. Mr. H. Z. (No. 2), on the other hand, feels no better when the red cells are lower. So, for the present at least, there is nothing to be gained by this form of therapy in his case. This man is something of a problem; the psychiatrists call him a "schizoid personality," but he is not definitely psychotic. Levin¹⁶ found nine cases of psychosis in erythremia in the literature, and reported one of his own. Although, as he says, mental disorders may be rare in polycythemia vera, at the same time one is often impressed with the multiplicity of complaints that some of these patients have. this group at least two more may be said to be neurotic and inclined to find new symptoms (No. 4 and No. 7).

Much as we should like to be able to advocate phenylhydrazine in all cases, it does not seem to be necessary for patient No. 3, nor advisable for patients No. 4 or No. 5.

Mr. I. B. (No. 6) might have been helped by the drug, but he refused to take it and so that settled the question.

Although Mrs. W. (No. 7) is a good example of the type of individual who should *not* take phenylhydrazine, it was given her, more or less in desperation, as a last resort, and instead of being harmful, has been beneficial.

Mr. M. G. (No. 8) and Prof. F. (No. 9) both seem definitely better after taking the drug constantly for long periods. This is particularly interesting in the case of Prof. F, as various other forms of treatment had not been successful.

The last patient (No. 10) is probably susceptible to the drug, and twice has been jaundiced, once after too much of the drug, and again after comparatively small doses.

Notwithstanding this, he is much improved clinically and says that he feels "one hundred per cent better."

Of these ten cases, all of whom have been given phenylhydrazine three have been markedly jaundiced and one very slightly, but as far as we can see, in no case has there been anything but temporary inconvenience and there has been no indication of permanent damage. The symptom is certainly an indication of too much of the drug and should be avoided if possible. Sometimes it will appear most unexpectedly after small doses, as in patients No. 1 and No. 2, and sometimes when the tolerance of the patient is apparently known (No. 8).

It is too much to say that phenylhydrazine is the best method of treating erythremia, but it certainly has some advantages, not the least of which are convenience and moderate cost. In a chronic disease, these considerations are of real significance. In patient No. 9 it was helpful when radiotherapy had failed.

It may be advisable to use phenylhydrazine in combination with radiotherapy, but in this series, as far as possible, we have attempted to study the effect of the drug alone.

Of the ten patients treated, seven were male and three female; six were Jews; three were Americans, one was a Turk. All save one had palpable spleens (two were just felt at costal margin, four from 4 to 5 cm., one was 8 cm., one 10 cm., and one 17 cm. below the costal margin). There is, of course, usually some decrease in size of the spleen after treatment, but this is not always constant.

Mrs. H. (No. 4) had a very high platelet count (930,000). Although these patients are said to have high platelet counts, such an increase as this is, we think, rather unusual. Incidentally, she has been a difficult patient to treat. Her symptoms seemed to be out of all proportion to the blood picture.

In this series of ten patients, five seem to have been benefited by phenylhydrazine (patients No. 1, No. 7, No. 8, No. 9, No. 10). Of these, two are outstanding and the improvement is sufficiently marked and has endured long enough to be significant (patients No. 8 and No. 9). These two patients have been followed long enough to exclude the possibility of normal remissions. These results may not be considered noteworthy, but it must be recalled that this is a chronic condition and not easy to arrest. Taschenberg¹⁷ thought there

was danger of the drug losing its efficacy after long usage. The opposite would seem to be true with these two patients.

The drug, although not fool-proof, has its value and is often indicated, especially in the earlier cases. Unfortunately, it is not possible

to say what may be considered a safe maintaining dose. This must be worked out for each patient individually, and even when this is done, every patient that is under treatment should have blood examinations at frequent intervals.

Conclusions

1. Five out of ten patients were apparently benefited by phenylhydrazine. For various reasons, the others did not take the drug long enough to afford any satisfactory evidence. Except for jaundice, no ill effects were observed. The drug is dangerous and its use is not always advisable. Careful observation and the adjustment of the doses probably reduce the danger considerably.

2 Each patient is a "law unto himself" and

a high blood count does not necessarily indicate phenylhydrazine.

3. Phenylhydrazine should never be given unless the patient can be kept under close observation and the blood count noted every week or two.

4 Though phenyllydrazine cannot cure polycythemia vera, it often refieves symptoms and makes life happier, with but little loss of time for the patient.

EXPLANATION OF CHARTS

The unbroken line represents the red blood cell count, ond the broken line the hamoglobin,

Each square is equal to 200,000 red cells and 2 per cent hamoglobin when considered up and down. When considered from left to right coch square represents two weeks, so that every chart covers two years' time. The lines at the top of the chart indicate the disage of phenylhydrazine, each square equaling 02 grain of the drug.

The large crosses, completely filling the squares, indicate idendice, the degree of which is shown by the number of crosses Stars on Chart III indicate radiotherapy.

PSYCHOPATHIC PERSONALITY

By JAMES L. McCARTNEY, M.D., DIRECTOR

From the Classification Clinic, New York State Department of Correction, Elmira Reformatory, Elmira, New York

PSYCHOPATHIC personality is a clinical condition in which character anomalies are in the foreground. It is not a general expression to indicate departure from the psychically well-adjusted group, but it has its own special connotation, its own special symptomatological picture or clinical syndrome. Nor does it refer to other psychiatric disorders that have come to have their own designations, such as demential praecox; manic-depressive psychosis, certain of the epilepsics, the psychoneuroses, the organic

psychoses, etc. The type of disorder now most commonly called psychopathic personality was first called "constitutional psychopathic inferiority," by Adolf Mcyer¹ in 1906. In order to cover the literature on this syndrome, it is necessary to remember that the following terms have also been used to designate this misunderstood condition: Constitutional Inferior, Constitutional Psychopathic Personality, Psychopath, Constitutional Psychopathic State, Moral Imbecile, Constitutional Defective,

Defective Delinquent, Emotionally Unstable or Inferior, Neurotic Constitution, and Instinct Character.

The "Statistical Manual" requires us to consider as psychopathic personalities a large group of persons showing abnormality expressed mainly in the character and intensity of the emotional reactions.

Psychopathic personalities are persons having anomalies of character which, because normal to the individual, cannot be said to be evidences of a psychosis. They lack continuity of purpose, fixity of ambition, and show a poverty of sentiment. They often show special or peculiar reactions such as tendencies towards habitual delinquency, pathological lying, eccentricities, sexual perversions, kleptomania, pyromania, etc.

In psychopathic personalities there are no known organic alterations acting as etiological agents. When a psychiatric syndrome resembling psychopathic personality is engrafted upon a recognized organic disorder, such as epidemic encephalitis, it is the practice to classify the situation according to the organic disturbance. Furthermore, there is no uniform finding in the field of intelligence in this group. Intellectual capacity may be below or above the average, or average. As Bleuler says about this group, "even if there is an average or greater intelligence, it has little regulating influence on action of the psychopathic personality."

Strecker and Ebaugh state that the psychopathic personality is an individual ill-equipped from birth to meet the demands of his environment. There is an apparent constitutional lack of responsiveness to the social demands of honesty or truthfulness or decency or consideration for others which incapacitates the person from settling down to any permanent standardized activity. He is therefore emotionally unstable, not to be depended upon, acts on impulses, shows poor judgment, is constantly led into unwise activities. Since the difficulty cannot be traced to any definite disease or organic process, the conclusion is that there is some constitutional lack of endowment.

The psychopathic personality may be recognized in youth, although it does not necessarily follow that the character traits may be perpetuated into adulthood. This type of person is prone to associate in a group life in which he can take leadership, and is often sly and cunning and gains his aims by unscrupulous means. Not infrequently these children are pugnacious and may be known as "toughs." They like to lead gangs into illegal pursuits, or, if that can not be accomplished, they may imagine they occupy the role of leader and recount imagined exploits as if they had really happened. As a rule, they do not get along well in school, for they are unmindful of classroom order, they may actively antagonize

their classmates or the teachers, and they are apt to play truant. When they do not have their own way they often develop tantrums of a severe grade. If they continue these traits into puberty, they are easily involved in criminal activity. Many thieves, liars, swindlers, forgerers have the background that has just been described.

Richmond² says that the psychopathic personality as a child is apt to be as hard as nails. He is with difficulty trained in habits of cleanliness, and it is not true of him that a burnt child dreads the fire. There is a marked superficiality of emotional life. Abilities are irregular; he may be very bright and yet show marked lack of judg-The psychopath does not adjust to any environment except one that he can dominate. He learns apparently only that which he chooses. In his love relations he demands everything and gives nothing. He is an egoist, and seems to be living in a world of his own. He is a difficult child to deal with. Promises are broken, appreciations of truth is beyond him, the gratification of his own impulses seems the thing worth while Because of the tendency to phantasy one cannot be sure that one is getting anywhere in tracing the origin of his difficulties.

Dooley describes the psychopathic woman as one who shows less ability to subordinate herself to the social group than the ordinary person, who cannot work or wait for deferred pleasure, is likely to be extravagant and a drifter in occupations, cannot acquire stable habits or fixed principles. and seems never to advance beyond infancy in making gratification of the desire of the moment the goal. She rebels against discipline, displays egoism and jealousy; she makes few friends, and is apt to choose those who are younger. There is superficial quickness and imitative power. The sexual instincts may be quite normal, although there may be homosexuality in practice. There is an overweening desire for sympathy and petting. There is seldom sincerity in the interest in reeducation.

Hinsie³ states that the psychopathic personality of adulthood is characterized by irresponsibility. carelessness, blunting of the ethical senses and disregard for the opinions of others in matters of ordinary conventions. It is often difficult, if not impossible, to distinguish between this type of psychopathic personality and the simple form of schizophrenia. Many authorities are inclined to regard sexual perverts as psychopathic personalities, particularly if the perversion forms the principal or sole outlet for sexuality.

Psychopathic personalities may be conveniently divided into three types, as follows:

First, those whose mal-adjustment appears to be due to deficiencies on the organic level, and therefore might be known as organic inferiority. These persons show mal-adjustment very early. This group includes the anti-social, mental defec-

tives, as well as cases with "stigmata," such as infantilism and dysfunction of the endocrine

glands.

Second, those showing inherent or acquired abnormalities at the psychosocial level. They show psychopathic family traits; there is no intellectual deficiency, and there are no marked physical anomalies. They are seclusive, suspicious, oversensitive, lack fixity of purpose, are drifters, often have feelings of inferiority, are emotionally unstable, submissive, and anti-social. They are often hysterical, epileptic, neurasthenic or psychasthenic.

Third, the social psychopaths, or "sociopathic," whose abnormalities of adjustment are usually acquired. They are difficult to manage at home. They are very alert, very aggressive, markedly egotistic, and narcissistic. Almost always there is a strong father antagonism shown in analysis. They are full of schemes, lack fixity of purpose.

The percentage of psychopathic personalities found in delinquent populations have been given considerable attention, with the following results:

	Cascs	Per cent
Glueck	608	18.9
National Committee for Mental		
Hygiene	1288	42.2
Bingliam	300	43.0
Stearns	107	12.2
Glueck	113	6.2
Raphael, et al	1988	36.8
Olson	2861	24.9
Gregary	1288	77.0

Examinations of 1046 new admissions classified at the Elmira Reformatory during the fiscal year 1931-32 showed that there were 32.4 per cent psychopathic personalities amongst these men, which might be divided into types as follows:

Type I-Constitutional organic inferiority-1.1.

Type II—Psycho-social psychopath—5.1.
Type III—Sociopath—26.9.

There is no recognized nor outlined special therapy for the psychopath personality as yet, and the general tendency is to regard the psychopathic maladjustments as fixed and incurable; and of course those who consider these states as inherited are already committed to the pessimistic outlook. Those who find in the endocrinological regions the etiology of personality difficulties, delinquency, ctc., or in any way introduce physiological concepts and biochemistry into the personality formulas naturally find some hopefulness in the development of therapy along this line. Prolonged analysis has given some encouragement, but work in the therapy is extremely limited.

Karpman states that the psychopathic person-

ality is seldom sincere in his wish for re-education, makes but a weak, fluctuating transference, which is superficial. O'Mally has much the same opinion, and states that he is so egocentric, so narcissistic, he is so well-satisfied with himself, especially with his behavior, that little can be done with him analytically. He likes the attention given by the analyst and tries to retain his difficulties. Successful transference cannot be obtained. He feels that if the psychopathic components were removed much of happiness would be taken out of life. Analysis is resisted, and the love life is satisfied with self love. Richmond thinks that because of the tendency to phantasy one can never be sure that one is getting anywhere in tracing the origin of the psychopath's difficulties.

CASE #987

A 19 year old boy of Polish-Jewish ancestry, of dull normal intelligence with a Stanford Binet age of 12 and an IQ of 80, with a performance age of 9; having very poor construction ability; he is five fect and 34 inches and weighs 100 pounds. He shows a heart murmur at the base of the heart, but which is not transmitted. He has a mottled skin, a feminine distribution of hair, is in fair physical condition, and shows normal neurological findings.

His father, 52 years of age, born in Poland, of Jewish ancestry, came to U.S.A. about 22 years ago, is literate, temperate, a citizen, and a baker by trade. Mother, 50 years of age, born in Poland, came to U.S.A. with the father 22 years ago, is a citizen, illiterate, in good health, a housewife, had four children of which inmate is the

youngest.

Inmate was born in N. Y. C. Birth was without pathology. Nothing much is known about his early childhood except that he began school at 5, continued until 15 and reached the 6th grade; then, for some reason or other, he was immediately jumped to the 8th grade. Inmate can give no reason for jumping these grades, complains that he could not do the work. The only illness he had during his childhood was whooping cough; when 17 years old he suffered a very severe head injury and as a result sustained a right facial paralysis. On leaving school he worked in a women's dress factory as a stock clerk, worked fairly steadily until the firm went bankrupt. He was out of employment for about 6 months prior to his arrest. As a boy he was a member of the Boy Seouts, but he was not interested in their organization, and after six months did not attend the meetings. On leaving school he began going around with a gang, and on losing his position in the factory he began to earn some money bootlegging. While delivering some liquor he was urged to handle narcotics and made good money selling the drugs, but was apprehended by the Federal Agents, was arrested and pleaded guilty.

He was sentenced to 15 months in the Reforma-

Psychiatric examination showed that this boy has a marked feeling of inferiority, feels that he has a very bad heart murmur, and says that he is in poor health, which is borne out by his appearance but not from the physical examination. This man has caused some trouble while at the Reformatory because of his psychopathic make-up, which was diagnosis of organic inferiority type. The prognosis for the future is very bad.

CASE #52393

A 19 year old boy of English-Dutch ancestry, of normal intelligence with a Stanford Binet age of 15, an IQ of 100, a performance age of $15\frac{1}{2}$, normal construction ability, weighs 145 pounds and is five feet 10 inches. As a child he was said to be in very poor health, undernourished. During his childhood he had measles, mumps, chickenpox, scarlet fever and pneumonia. On admission to the Reformatory he was physically found to be in good condition, with no evident

physical pathology.

The father, born in U.S.A., of English-Dutch ancestry, literate, intemperate, and a laborer; was very cruel to his family. He was arrested on a charge of burglary, sent to Auburn Prison and died 2 years later while in prison, from diabetes, when 66 years of age. He had been a painter by trade and had a very bad reputation in the neigh-Mother, born in Canada, of English ancestry, 64 years of age; following her husband's incarceration she worked in a steam laundry, but because of poor health and nervousness, had to quit and has lived on charity since. She had 8 children, only one daughter who died at 9 days old; inmate is the youngest child in the Three brothers of this inmate have served time in the Reformatory, and two of these brothers are now in Auburn Prison, on other charges.

Inmate was born in a small N. Y. town, when the mother was 45 and the father 51. He was always considered very nervous, but obedient although unreliable; was easily led, but he would work at anything he was offered. According to the mother the inmate's older brothers did not care for the inmate, who had to take his own part at all times. He was always very fond of music, could play the violin by ear and was very interested in mechanics, said to be very good in elec-. trical work and auto repairing. He began school at 7, continued until 16, finished the 7th grade, had no special ambition and on leaving school he worked in a paper mill as a laborer, for about 6 months; but he soon quit, worked at odd jobs and was frequently unemployed. He began to walk and talk at about 2 years of age, but was always considered dull in school, although our psychological examination shows him to be of normal

intelligence. Inmate stated that he never failed in his studies. He was first arrested when about 9 years old, when he stole some money from a milk fund in school, and from then on he was arrested 12 times, but never served time before The family was always in very bad financial condition, and inmate finally stole a roll of canvas worth about \$40 and was sentenced to the Reformatory for a term of 3 years.

Psychiatric examination of this man shows him to be emotionally unstable, having a marked feeling of inferiority, very aware of his bad family background, having had a poor school and working record, and who was physically ill as a child. He is the youngest of a large family, has always been lazy and shiftless, somewhat introverted, shy and retiring; a definite psychopathic personality, of psycho-social type, and is very irritable, who has found security in the Reformatory. The prognosis for the future is bad.

Case #14393

A 19 year old boy of Italian ancestry, who is of dull normal intelligence with a Stanford Binet age of 13, an IQ of 87, a performance age of 16, with

excellent construction ability; physically in good condition, weighs 169 pounds and measures 5 feet, 634 inches. He had no special illness as a child, was operated on for hemorrhoids about 6 years ago, when 13 years old, and had gonorrhea when 15 years old, for which he received treat-The father, died at the age of 51, following the death of his son, who was shot by the police when he attempted to get away from the scene of a crime. The father was born in Italy and came to

U.S.A. about 27 years before his death, was a citizen, practically illiterate as to English, was a moderate drinker, a shoemaker by trade who was well respected in the neighborhood, and apparently died from what was thought to be grief following the death of his son. Mother, 49 years of age, born in Italy, came to U.S.A. with the father 27 years ago, is illiterate, a citizen, a housewife, in good health, although she continually worries. She has had six children of which one died, inmate being the fifth in the family. The family lives in a four-room apartment, in a fourfamily house owned by the mother, who is highly respected in the neighborhood.

Inmate was born in N. Y. C. He began school at 5, continued until 14. He was frequently absent, but had good deportment, was considered an average pupil. He was then committed to the Catholic Protectory because of truancy, where he was considered a dull pupil. He was then committed to a truant school and paroled as a graduate from the 8th grade when 14 years old. While in that institution his conduct and work were good, his progress in his trade was good. He was said to be over-indulged by his parents.

was allowed to spend most of his time on the streets. On leaving school he only worked in two For about 3 months he worked as a butcher's helper where he earned \$5 per week, but he quit. He then worked off and on for his father, in a shoe repairing establishment, for about 7 months without receiving any special salary; otherwise he had no working record. He went around with a gang, and prior to his last arrest he was unemployed for about 18 months, apparently supporting himself by his eriminal activities. He was arrested in 1929 on a charge of assault and attempted robbery, but the ease was dismissed. July 25, 1932, in company with three associates, two escaped and one sent to Sing Sing, they hired an apartment, went to a public dance hall, secured a dancing hostess, took her to the apartment, stripped her of her clothes, and when she would not submit to having intercourse with four men, she was knocked down. When they had gone to sleep, she took one of the men's overcoats, escaped, notified the police. Inmate was arrested, indicted for rape 1st degree which on a plea was reduced to assault the 2nd degree, for which he was convicted, sentenced to the Reformatory for a term of 5 years.

Psychiatric examination of this 19 year old man shows him emotionally unstable, rather paranoid, and coming from a good family background. He has been a problem all his life, has been sexually promiscuous and rather precocious in his sexual development, having had sex intercourse. the first time, when he was about 14, and has continued sex indulgences frequently since that time. He is antagonistic, a definite psychopathic personality of sociopathie type, without any conception of social requirements; a dangerous gangster who will always be in trouble. He has always been able to beat the law, as he has done in this case. He has no insight, and prognosis is bad.

PHYSICAL THERAPY IN DERMATOLOGY

By PAUL E. BECHET, M.D., NEW YORK, N. Y.

Read by invitation at the Forty-first Annual Meeting of the American Physical Therapy Association, Philadelphia, June, 1931.

NLY the essentials of this vast subject can be taken up in the usual allotted time, therefore it might be best to use that time to put before us the physical therapeutic opinions. impressions, and observations of twenty dermatologie years, rather than give you an alphabetical list of dermatoses with the exact definition of what particular apparatus might benefit each. It is the usual procedure, especially among the younger men, to commiserate our predecessors over their lack of the chromium niekeled, black, maroon, or grey enameled machinery of today. Such commiseration is needless, for I am old enough to remember the really very splendid cosmetie results often obtained by the dermatologist of the past generation with his very limited physical apparatus, yet I am young enough to appreeiate the enormous advances made since his day and to be grateful for the use of these modern methods. The most frequently used physical agents in dermatotherapeutics are the röntgen rays, radium, endothermy, ultraviolet light, refrigeration, and electrolysis. It might be well to consider these agents under separate headings, taking the most important one first.

X-Rays

This is the most important therapeutie agent in dermatology. Many skin diseases are either cured or improved by its use, it has done away with many obnoxious salves and lotions, and has contributed more comfort to the victim of a skin disease than any other single agent. As the years go on its sphere of usefulness does not diminish but on the contrary increases as our knowledge of its use increases. Like all useful measures it has its dangers. I have personally seen many deplorable results from its careless, ignorant, or eonscienceless use. Its employment in the treatment of diseases of the skin lies particularly within the province of the dermatologist, because he knows whether or not a particular dermatosis is amenable to the x-rays; and he is thoroughly acquainted with the results, complications, indications, contraindications, dosage, and other features. A correct diagnosis is essential, for after all the x-rays are not a panacea for all dermatologic ills; there are many skin diseases in which it proves of no benefit whatever and a considerable number which it actually aggravates. Overtreatment is a common error. It is a good plan

to use as small a dose as is consistently possible to obtain the desired result. Most of the dermatoses which yield to it do not require more than a quarter of a skin unit once a week. Only a very small group require a higher dosage. It is always better to err on the side of safety and give a little less treatment than too much. Patients are not grateful for the permanent atrophy and telangiectasia of a radiodermatitis, even though they are rid of their skin disease. On the other hand, with the low dosage of a quarter of a skin unit given once a week, eight to fifteen treatments may be administered without the slightest fear of any untoward sequelae. This is especially true of acne, in which disease the x-rays are almost a specific remedy; they are of the greatest value in all its stages, with the single exception of acne rosacea, in the treatment of which they often disappoint. The x-rays are the method of choice in the treatment of ringworm of the scalp. With careful technique the hair invariably regrows in a normal manner. Its brilliant achievement in this disease is due entirely to complete epilation, as it has no fungicidal value. Mycosis fungoides is not dreaded nearly as much since the advent of the x-rays; their use does not cure, but it stops the itching, causes the disappearance of many of the tumors and infiltrated plaques, and prolongs the patient's life by many years. The same result may be expected in multiple idiopathic hemorrhagic

Its value in basal cell epithelioma is known by all, but I do not depend on it alone in the treatment of skin cancer. I have been highly successful in the use of the following method, the various steps of which are done at the same time: (1) electrocoagulation; (2) thorough curettage of the softened mass with a very sharp curette; (3) electrodesiccation of the curetted surface; (4) two to four skin units of unfiltered x-rays. This method may sound a bit strenuous, but in reality it is not and the cosmetic results are very good. I much prefer an atrophic scar with perhaps slight telangiectasia to a recurrence of the epithelioma. I have had no experience with epithelioma of the lip for the simple reason that I consider this type of malignancy as being without the sphere of the dermatologist; it belongs to the surgeon, as resection of the lymphnodes is so often required. Radiotherapy should only be used as a postoperative measure to destroy whatever cancer cells might be left by the knife. Eczema, psoriasis. and lichenification at times give way to the x-rays in a remarkable manner. but they are rarely permanently cured and frequently recur. Röntgenotherapy should therefore be used most cautiously as it is easy to give an overdose through the repeated treatments of recurrences in the space of years. It is disconcerting to note patches of eczema or psoriasis occurring on the site of a radiodermatitis, caused by previous attempt to overcome the same disease with the x-ray. Other dermatoses in which röntgenotherapy is of great value are granuloma annulare, scrofuloderma, verruca plantaris, tinea barbae, and sycosis. In the last two diseases radiodermatitis is a most common sequel because of the repeated epilating doses. I have attained very much better results in sycosis with the smaller doses of one quarter of a skin unit once a week, thus abolishing the epilating dose. It is however at best a most intractable disease. Before leaving the subject of the x-rays may I be allowed a word in reference to their use in hyper-They should be condemned unqualitrichosis. fieldy. There is hardly a single dermatologist in active dispensary and private practice who does not within a year observe a number of unfortunate women badly disfigured by their use. Patients should be warned and told that the only safe measure for the removal of superfluous hair electrolysis. These permanently disfigured women have in most instances been burned in the offices of various concerns advertising the removal of superfluous hair by actinic measures, but at the same time hiding from their patients the fact that the x-rays are being used.

The supersoft röntgen rays with wave lengths averaging two angström units and known as the "grenz" rays have also a field of usefulness. They are however still in the experimental stage. They were believed at first to be absolutely free of any danger, even in large doses, but it is now known that atrophy and telangiectasia do occasionally occur although not nearly to the same extent as after ordinary x-rays.

Radium

The action of radium in a general way is similar to that of the x-rays, but the technique of its dosage is not as easily mastered as of the latter. Untoward results are for this reason much greater after its use than after the x-rays. Its greatest field of usefulness in dermatology is in the treatment of vascular nevi, small epitheliomas of the basal cell type, small keloids, senile keratosis, and Occasionally subungual warts plantar warts. disappear after its use. In my experience the smaller the lesion, the better the results. It should not be used for such dermatoses as nevus flam-In treating meus and pigmented hairy moles. vascular nevi or small angiomata the best results are attained in the lesions of shortest duration. It is therefore best never to defer the treatment until the child is older. The advent of endothermy has seriously curtailed the popularity of radium in dermatology. It remains however a most valuable agent in small angiomata. The cosmetic results after the careful use of radium in these lesions are splendid.

Endothermy

Surgical diathermy is outranked in importance in dermatotherapeutics by the x-rays only. Electrodesiccation and electrocoagulation are the two modalitics most used. They have proved an Ideal method in the removal of skin blemishes, such as moles, warts, granuloma pyogenica, telangiec-tasia, and small vascular nevi. Electrosurgery is of supreme importance in the destruction of eutaneous malignant growths. Its action is very rapid and inflammatory reactions are more severe than those following galvanocautery or electrolysis. However in the hands of an experienced operator the cosmetic results are exceedingly good. As in everything clse, experience is essential in the attainment of successful results. The cutting current is more important to the surgeon than to the dermatologist; it is however very useful to the latter in the removal of subcutaneous tumors.

Ultraviolet Rays

This apparatus now occupies the corner of almost every large beauty shop and barber shop in our broad land. Even the home has not escaped. Of course only a small quantity of these lamps are therapeutically efficient; otherwise they would have caused even more damage than they actually have. They have also been exploited I am sorry to say by a goodly number of medical men, either for the sake of financial returns or misdirected enthusiasm. The manufacturers have been responsible for much of this craze, for in their anxiety to make sales they have had printed in their brochures the most extravagant claims. From a dermatologic standpoint what are its actual benefits? They are very few, The water cooled lamp by the decompression method is of value in lupus erythematosus, adenoma sebaceum, nevus flammens, and possibly in the superficial type of lupus vulgaris; the air cooled lamp in pityriasis rosea, angioma serpiginosum, alopeeia areata, acne vulgaris, and psoriasis. In none of these, with the possible exception of nevus flammeus and adenoma schaceum, does it actually cure. As far as its value in premature baldness is concerned, I would like to quote the conclusion of a paragraph in a recent article by Fred Wise, who referred to it as "that form of refined suggestive therapy which induces wealthy baldheaded men to rest and meditate under an ultraviolet halo at certain prescribed intervals."

Refrigeration and Electrolysis

Carbon dioxid snow has undeservedly lost its popularity. It is a most efficient agent, and its cosmetic results are as good as, if not better than those of more popular agents. The difficulty of making proper sized carbon dioxid ice applicators has been entirely eliminated by the Lortat-Jacob eryocautery apparatus, in the use of which I have had much satisfaction. Refrigeration is the method of choice in pigmented nevi and superficial angiomata. It is also of great value in very superficial lupus vulgaris and senile keratoses. It was frequently used in lupus erythematosus before the advent of gold and sodium thiosulphate. Electrolysis is the oldest physical therapeutic method in dermatology. It was widely employed in former years, and I have seen very many splendid results from its skilled use. It is today in the discard, with the exception of its use in the removal of superfluous hair, for the relief of which anomaly it is still the only safe method. It also proves of great value in telangiectasis.

Conclusion

In conclusion it will be noted that many of the different physical therapeutic methods advocated are used for the relief of the same dermatoses. The choice of any particular method is determined by experience alone, and this experience must be acquired. It cannot be imparted by word of mouth, If this humble effort to place before you the salient facts of this vast subject proves of some slight assistance, I shall feel most gratified.

INVESTIGATIONS OF MEDICAL SERVICES

A number of studies of the distribution of medical services have been made during the last few years, especially from a sociological point of view. All the investigators agree that medical science is abundantly able to cope with the largest proportion of the ills to which the human race is subject; and that the practicing physicians of the United States could give satisfactory service to all the people if the system of practice were adapted to that purpose.

Economic Conditions: The majority of the investigators of medical services have been so-

ciologists and economists who have emphasized their own specialties in their studies. They have secured data regarding the relation of the financial conditions of the sick to the medical services which they receive; and as a result they have classified the people into three groups according to their individual ability to pay for the medical services which they need:

- Those able to pay for all.
- Those able to pay for part.
- Those able to pay for none.

Physicians generally agree with the sociol-

ogists in their economic classification of patients. Doctors also agree with their proposal that the community or State, shall provide that part of medical service for which an individual cannot pay. But physicians wish to retain the personal relation of the individual patient to the individual physician which is lacking in the impersonal, bureaucratic methods of state medicine and group insurance proposed by the sociologists.

Investigations by Sociologists: The problem of the medical care of the indigent is comparatively simple. There have always been "poor laws" in the United States, and physicians are actively cooperating with government officials in devising relief methods which shall be of mutual satisfaction to the medical profession and the community. This Journal of the last six months carried accounts of these activities in six states and in four counties of the State of New York.

More complex is the problem of medical service to those able to pay for part of their care, and for whose bencht sickness insurance is proposed. Physicians are suspicious of insurance plans because of the abuses of the system, as in Cuba. (See this Journal August 15, 1933, page 1001.)

The outstanding study by sociologists and economists is that of the National Committee on the Costs of Medical Care, whose report was made public on November 29, 1932; and the remedy proposed by that committee may be summarized as that of a group action by the people, especially in the form of insurance for medical and hospital care during sickness, beginning with voluntary groups.

Investigations by Health Departments: Departments of Health have also conducted studies in the distribution of medical services, especially in the lines of prevention, although they also propose to enter the field of treatment. An outstanding study along this line was that made by the Governor's Health Commission of New York State, whose report was issued in a printed volume late in the year 1931. The report dealt principally with the problems of administrative medicine and discussed the duties of all governmental officials to provide for health protection on the same bases that they provide for education, police protection, and other governmental activities. The report was considered at a special meeting of the House of Delegates of the Medical Society of the State of New York held on January 14, 1932, and nearly every recommendation was adopted, except that making county health departments mandatory.

Investigations by Medical Societies: Few extensive investigations have been initiated and conducted by medical societies; but an outstanding

one is that which was conducted by the Michigan State Medical Society into the medical agencies of Michigan. Its report is described on page 1061 of this Journal. While one may criticize the report as emphasizing the impersonal, the statistical, and the financial aspects of medical service, and for the paucity of its recommendations, yet it is a demonstration of how an investigating group composed of practicing physicians will conduct a study of the problem of health service. As a matter of fact, the report followed the style and content of that of the National Committee on the Costs of Medical Care.

The County Society: The Michigan House of Delegates asserted a principle which will doubtless prevail in establishing any new method of medical service. Physicians are opposed to application of a new method to any large group of persons who are unprepared to adopt it voluntarily and to cooperate in its execution. The method suggested by the Michigan House of Delegates is that a new system shall be approved when the physicians of a county ask for it through their county medical society. That has been the system by which the existing county health departments in New York State have been established. The Michigan physicians voted to approve health insurance for any county in which the doctors shall put it in operation voluntarily.

The Future in Michigan: The physicians of Michigan have set an example of leadership in conducting an investigation of medical services. While the House of Delegates voted to discharge the investigating committee, yet it appointed its members as the personnel of a Committee on Economics to continue the study. The committee will have precedents for some of its investigations, but must do pioneer work in other lines.

The committee has an abundance of precedents on which to base its action for the care of the indigent, for many States and Counties have experimented with their care during the past two years, and have developed methods which are standard.

There are fewer precedents for the care of those who are able to pay some part, but not all, of the costs of medical services. An outstanding precedent is that of New York State, whose Welfare Law has been in operation for over two years.

There is a large group of persons who have sufficient thrift to take out policies insuring medical and hospital services during sickness; but for this group the Committee will find very few precedents in this country.

The action of the Michigan Committee will be awaited with keen interest by the medical profession throughout the United States.

MEDICAL PROGRESS

The Incidence and Severity of Arteriosclerosis in the Organs.-The fact that a common diagnosis is that of "generalized arterioand that the pathologist may sclerosis' encounter difficulties when he attempts to correlate clinical with pathological findings led William B. Wartman to undertake a study of 500 autopsy records to determine the incidence, distribution, and degree of arteriosclerosis in the various organs of the body. The order of frequency with which the arterioles and small arteries of the organs were affected was: spleen, brain, kidney, adrenal, pancreas, heart, gastro-intestinal tract, lungs, liver, and diaphragm. This is in agreement with the observations of most investigators. It was found that those organs which were most often involved were also most markedly affected by an arteriosclerotic process. The arteries of the spleen, brain, and kidney were sclerotic, for example, in 70 per cent. or more of the cases and of these at least 60 per cent, were involved to a marked degree. In the diaphragm, liver, lungs, and other organs which were infrequently implicated, there was a high incidence of the milder forms of sclerosis and a low incidence of the more advanced forms. Perhaps the most striking feature of the investigation was the rarity of sclerosis of the diaphragmatic arteries, 5.6 per cent., and no case showed marked involvement.

The heart, the pancreas, and the adrenal bodies showed an approximately equal incidence of mild and of marked arteriosclerosis. An important exception is the interesting fact that the brain, although it did not show the greatest total percentage of arteriosclerotic cases, did present the highest incidence of marked involvement. It was found that the incidence and degree of arteriosclerosis increased with the age factor; in the age group (60 to 90 years) the spleen and kidney showed sclerosis in more than two-thirds of the cases. A review of the literature as well as the results of this study indicate that a generalized arteriosclerotic process of a degree sufficiently advanced to be of clinical importance occurs infrequently. diagnosis of generalized A arteriosclerosis should be made with caution and only on the basis of adequate evidence. The clinical features in such cases should be carefully correlated with the histological findings at autopsy, for it is only in such a manner that clarity on this subject will be reached.— American Journal of the Medical Sciences. July, 1933, clxxxvi, 1.

The Etiology of Nocturnal Enuresis,- W. H. de B. Hubert presents a study of 100 cases of enuresis treated at the Maudsley Hospital Child Guidance Clinic and also 50 unselected cases attending the clinic for other reasons. The 150 children were divided into three groups: Group 1 consisted of 50 children referred for treatment by care committees and district medical officers from the elementary schools; Group II of 50 cases of enuresis referred from residential schools; Group III of the 50 unselected cases, mostly children having anxiety states, which served as a control group, The most interesting finding was the frequency with which enuresis appeared in the parents or their siblings, 40 per cent, in Group I as compared with 14 per cent. in Group III. In the other 50 cases the family histories could not be obtained. In the enuretic group 8 per cent. had a history of epilepsy in other members of the family; in Group III, 6 per cent. The numbers are too small to warrant conclusions, but the finding appears to be worth mention-The intelligence of the children sent to the clinic for enuresis was very similar to that of children referred for other reasons. The age of onset was variable; 58 per cent. were said to have wet the bed since birth; 32 per cent. had been trained in cleanliness, but from 3½ to 5 years had commenced nocturnal enuresis, while 10 per cent. showed it only later in childhood. Additional diurnal incontinence was shown by 12 per cent, which in 6 per cent. was combined with fecal incontinence. No relationship could be demonstrated between the amount of urine in the bladder and the time and amount of enuresis. depth of sleep was varied by the administration of sedatives, but this produced no variation in the enuresis. In Group I complete recovery occurred in 40 per cent. of the children. The recovery rate in Group II, those from residential schools, was much lower. This may be related to the fact that in these children careful attention and routine had already failed. Results seemed to depend almost entirely on the individual treatment of the child. No special drug appeared to be of particular value. Belladonna did not seem to possess advantage over any other drug prescribed with equal apparent confidence. Similarly, while limiting fluids and instituting a strict régime was often successful, an equally dramatic cessation of such a system produced good results. Adjustment of single factors in the environment, relief from particular strain, such as undue

pushing of a clever child, was sometimes successful. In all cases an alteration, so far as possible, of the attitude of the parent and child to the trouble was attempted, and an endeavor made to increase the child's understanding of the emotional trends related to this abnormality. No definite correlation between improvement with treatment and absence of hereditary factor could be made.—

The Lancet, June 17, 1933, eexxiv, 5729.

Late Sequels in Stomach and Intestine Following Bacillary Dysentery. — Bacillary dysentery, according to Adolf Ohly, who writes in the Deutsche Medizinische Wochenschrift of May 19, 1933, is followed in so many cases by not only early but also late sequels that a knowledge of these disease pictures is of great diagnostic and therapeutic importance. While it is not easy to bring the late sequels together under a single heading, or to classify them into definite groups, for practical purposes they may be divided into a diarrheal and a spastic-hyperalgetic form. The symptomatology may concern either the stomach, small intestine or colon, or all of these simultaneously. For diagnosis a thorough examination of the entire alimentary canal is necessary, since a large proportion of cases assume the form of a chronic recurrent gastro-enteritis, or gastro-enterocolitis. In the majority, disturbances of the colon occupy the foreground of the picture. The diarrheic forms run their course as a rule without pains, in contrast with the spastic hyperalgetic forms, which are relatively frequent and are characterized by presence of eramping pains. Colitic conditions unquestionably play the major part in the picture. These late sequels are much more stubborn than similar nonspecific conditions, and hence offer a less favorable prognosis, having a tendency to recur, especially after error of diet or exposure to cold. A sparing diet must be carried out as a permanent measure in a considerable number of cases, especially where there is irreparable injury to the mucosa. In other cases it may be possible gradually to increase the functional capacity of the intestine until a moderately liberal diet can be tolerated. An excess of cellulose must be avoided. Fresh raised bread, very fat meats, and cold drinks are harmful, and only small quantities of food should be taken at each meal. In cases where carbohydrate fermentation and diarrhea are the predominant symptoms, the following regimen has been found beneficial: One day of fasting, on which the patient receives nothing but tea or camomile tea; then a week without any carbohydrate but with small amounts of boiled meat, fresh cottage cheese, and in severe cases albumin water. All milk given must contain lime water. After 3-6 days of this strict protein diet, the patient may have noodles, rice, zwieback and buttered toast for a week. Then,

cautiously, small amounts of cooked and strained fruit and vegetables may be given. Not until another week has passed may the patient have potato in the form of a puree, this being the stareli least tolerated. In cases of achylia, hydrochloric acid pepsin combined with pancreon in large doses may be administered. In the spastic-hyperalgetic cases antispasmodics (atropine, papaverine or eumydrine) are indispensable. Hot applications, such as mud packs, hot Priessnitz bandages, and diathermy are useful. In addition, the value of mental suggestion must not be overlooked, since these patients are prone to suffer with fears of tuberculosis and cancer.

Ninth Day Intertherapeutic Erythemas.— It has been usual, says M.G. Milian, writing in the Bulletin de l'Académie de Médecine of May 23, 1933, to regard as toxic any eutaneous eruption that appears during a course of medication. This conception, however, is inexact, and must give place to the view that 2 types of eruption exist under such conditions, one toxic and the other not. A toxic eruption is always the same for any given medicament, its appearance invariably recalling the toxic symptomatology belonging to that medicament. Nontoxic eruptions, on the contrary, have the characteristic of being multiform, that is, for any given medicament they may assume the most varied aspects, resembling now scarlatina, now measles, now roseola, etc., or even assuming a polymorphic form. They appear ordinarily about the ninth day, and for this reason they are called by Milian "ninth day erythema," in order to register in their title this essential chronological character. The nine-day interval is the same, irrespective of whether the medicament in question is given by mouth or intra-muscularly or intravenously. The same eruption may follow multiple and very different medicaments, such as pentavalent arsenics, trivalent arsenics, salts of gold, nirvanol, barbituric compounds, etc. These eruptions reproduce none of the toxic accidents due to a given drug: for example, none of them cause the vasodilator and edematous phenomena observed in arsenical intoxication. They cease after one or two mild recidives, notwithstanding continuation of the treatment in identical or even larger dosage, 3 or 4 times the first. It can be shown that they are infectious erythemas started up by the medicament. This is proved by numerous arguments; for example: (1) They are scarlatiniform, morbilliform, rubeoliform, roseoliform, or polymorphous, more rarely purpura-rheumatoid. (2) To each variety there corresponds a train of febrile and functional phenomena resembling, in attenuated form, those of the disease of its eruptive type. Thus the scarlatiniform erythema is preceded by an angina, headache, and vomiting; the morbilliform, by coryza, conjunctivitis, and bronchitis; the rubeoliform by multiple and often

وعليته فيمتوه فيتبادوه

quite marked lymph gland engorgements; the polymorphous, in 50 per cent of cases, by rheumatism and arthralgia. (3) These erythemas are nothing else than attenuated eruptive fevers appearing in individuals who harbor latent halfimmunized microbes. Such findings are of great practical and biologic interest. They make it permissible, with certain precautions, to continue a treatment with the same medicament in the same patient, and they absolve from suspicion a product which might be incriminated for accidents which are unrelated to its toxicity. They show the frequency of latent microbism in the human organism, the stimulation of this under multiple influences, and the possibility of controlling these infectious attacks by employing, not the antidote of the medicament, as one might be tempted to do, but specific remedies directed to the infection, when such are available, as for example, sodium salicylate in the arthropathies of acute rheumatism.

Cure of a Case of Acute Yellow Atrophy of the Liver.—In a case of acute yellow atrophy of the liver described by Tellgmann in the Deutsche medizinische Wochenschrift of June 23, 1933, it was impossible to incriminate as the cause any of the usual intoxications or infections known to be the forerunners of the condition. The hepatogenous origin of the feverish icterus was fully established by the chemical findings in the blood, stools and urine. In addition to hemorrhages into the skin, epistaxis and blood in the stools, there was in the first four weeks a variable fever, albumin with icterus cylinders in the urine and complete loss of appetite. The diagnosis of acute yellow atrophy of the liver was confirmed by the evident diminution of the liver dulness, the resistance of this organ on palpation being reduced, and by the finding of tyrosin in the urine in the second and third weeks of the illness. The cerebral symptoms characteristic of acute yellow atrophy of the liver were relatively mild, and justified a favorable prognosis or at least the conclusion that only a small amount of liver parenchyma had undergone autolytic destruction. When the general condition grew steadily worse as the result of insufficient intake of nutriment, and the usual remedies proved ineffectual, Tellgmann gave daily, from the third week on, 20 cc. of 50 per cent glucose solution intravenously, with 15 units of insulin twice a day, continuing the treatment for two weeks, with the result that the general condition improved and the severe icteric symptoms abated. The intake of nutriment was more satisfactory from day to day, and tyrosin could no longer be demonstrated. The diminished liver resistance continued; but albumin and cylinders could no longer be found in the urine. In the

first days of the attack the clinical picture was complicated by an iritis, for which the author was unable to find in the literature any connection with the disease. The coincidence, chronologically, of the abatement of the severe clinical symptoms with the daily injections of glucose and insulin warrants the conclusion that the process was favorably influenced by these measures, and that fatal terminal symptoms of intoxication on the part of the brain were perhaps in this way prevented from developing.

The Social and Economic Importance of Ocular Examinations.—L. Heine asserts that examination of the eyes by an experienced specialist may give invaluable diagnostic information to the clinician as well as to the neur-Slitlamp examination reveals at ologist. least two layers of the cornea, a superficial and a deep. Clouding of the superficial layers (nubercula, macula, leucoma, irregular astigmatism), points to scrofulosis, eczematosis, phlyctanulosis, whereas those in the deep layers suggest tuberculosis (sclerosing keratitis) or lues, especially the hereditary form (keratitis parenchymatosa). Keratoconus and its opposite, the dystrophies of the margin of the cornea, suggest disturbances of the internal secretions, especially of the genital glands. If dystrophies appear too early they indicate premature old age. One should think of hereditary lues if the vertical diameter of the cornea is greater than the horizontal, especially if this is accompanied by fungous atrophy of the iris. Another sign of congenital lues is found when the sclera is not, as in youth, just slightly bluish, or, as in old age, yellowish, but is blue in youth or slaty gray-blue The iris stroma may reveal conin old age. dyloma, gumma, tuberculosis, tumor metastases, cicatrices following such processes where these have healed, or may show diffuse and atrophies after luctic circumscribed tuberculous processes. The relative contraction or dilatation of the pupil may point to severe organic nerve and brain affections, especially where the reaction to light and convergence is disturbed; this may signify glaucoma, lues, tabes, or paralysis, and always points to disturbances of the whole organism and not merely to functional (hysterical) disturbances. A very small nuclear cataract in the middle of the crystalline lens indicates an endocrine disturbance of the mother during the first or second month of fetal life; a lamellar cataract of 3, 6 or 9 mm. diameter indicates such disturbance in the 3d, 6th or 9th month in utero. If clouding of the lens appears in the early years of life, one must think of tetany, myotonia, and diabetes. Clouding of the vitreous may signify a general constitutional disturbance. All morbid changes of the retina and choroid are likewise signs of general disease, often familial and hereditary. Furthermore, since the eye, as a sensory organ, is a portal of entry to the brain, serious defects in this region are liable to be attended by defects of intellect. It is thus possible, by accurate examination of the eyes, to uncover conditions the presence and propagation of which are a detriment to society, and which thus properly become a concern of marriage and industrial laws.—Deutsche medizinische Wochenschrift, June 16, 1933.

A Clinical Study of Aerophagia.-Julius Friedenwald and Samuel Morrison state that air-swallowing is a normal physiological proc-With each act of deglutition a certain amount of air passes subconsciously into the stomach and is eructed or settles in the upper left portion of the stomach, forming the socalled magenblase, stomach bubble. There is a form of aerophagia-eructatio nervosa-oecurring in individuals of a neurotic type, who have learned to swallow air voluntarily. This type of ractised by patients v · abdominal or cardia relief from discomfo' ordinarily an unimportant condition, it may become so aggravated as to undermine the patient's general health and thus lead to serious manifestations. When air is trapped in the stomaeh, as occurs in pneumosis, it may cause cardio-respiratory symptoms. Aerophagia may occur as the result of various digestive affections, of disturbances of the pharynx and of the salivary glands. It may be associated with gastric carcinoma, ulcer, acute and chronic dilatation of the stomach, gall-bladder disease, abdominal adhesions and intestinal obstruction, as well as with pulmonary and cardiovascular disease. The most common form of aerophagia is eructatio nervosa. In a series of 1,590 cases of gastric neuroses collected by one of the authors there were 54 instances of eructatio nervosa, 42 of which occurred in women. is important that the diagnosis of nervous eructations should be made only after a thorough clinical investigation has entirely ruled out organic disease. In the treatment of the mild types of eructatio nervosa much can be accomplished by explaining the mechanism of the act to the patient and admonishing him to control it. If this is not effective, treatment should be directed toward the neurasthenic state. Nothing will bring about such excellent results as a well regulated rest cure. In cases in which the eructations are violent and continuous, temporary relief may be obtained by placing a cork between the teeth to keep the mouth open. In acute attacks with pneumatosis the introduction of the stomach tube will afford instant relief. Drugs are usually of minor value; among those having more or less effect are the bromides, phenobarbital, and atropine. Boas advises the employment of physostigmine 1/6 of a grain (0.01 gm.), together with the extract of nux vomica, 1/3 of a grain (0.02 gm.) three times daily. In the symptomatic form of aerophagia treatment must be directed to the primary disease.—

New England Journal of Medicine, June 29, 1933, ceviii, 26.

Hibernation of the Common Mosquito .- M. J. Legendre says that in a three-year study of the common mosquito, Culex pipiens, he has observed certain peculiarities with reference to hibernation that appear never to have been pointed out. A dark and a light variety exist, and it is with the dark that his article is concerned. This type, breeding in surface waters, does not, like the light, sting human beings during the estivo-autumnal season, and when it enters habitations, it is not for nutritive purposes. The breeding season begins in the first half of April, and ends in the middle of December. About the end of September the mosquitos begin their entrance of houses, at twilight. During a 40-minute period the author counted 224 mosquitos in the moment of entering an entresol occupied by day but empty at night. They conspicuously refrained from entering the rooms on the floor above, in which three persons passed the night. They came while it was still light, singly or in small groups, following one another in a straight line as if by a familiar route, and alighting on the walls or hangings, where they remained motionless, appearing to sleep. Not one stung a person who was then sitting in the room. None of the abdomens showed any trace of blood from any kind of animal. All were females, and were characterized by fatty development of the abdomen. Microscopically there was no development of the ovaries, the size of the abdomen merely constituting the alimentary reserve for the winter. As the winter advanced, the fat bellies grew thinner. About February 1 all the mosquitos disappeared. was evident that they were not dead, for the species depended on them for continuance, and in the water receptacles there was no trace of eggs, larvæ, or nymphæ. Clearly the hibernation indoors was to be supplemented by another hibernation out of doors, during the two months that precede the laying of the eggs, one of which, February, is the most rigorous of the winter. Exactly the same behavior was observed in each of the three years of the study. No male was ever seen among the hibernating females.-Bulletin de l'Académie de Médecine, June 13, 1933.

LEGAL

PHARMACISTS-LIABILITY FOR NEGLIGENCE FILLING PRESCRIPTIONS

By Lorenz J. Brosnan, Esq.

Counsel, Medical Society of the State of New York.

The law imposes upon a pharmacist a very high degree of care. Not only is he under a duty to fill a prescription correctly, but he is under the further obligation in cases where he is not certain of the exact meaning of the prescription, to inquire from the prescribing physician as to the contents thereof. A case illustrating the latter principle in which a pharmacist was held accountable for negligence, was the subject of recent review by an appellate court in one of our mid-Western States.

A certain Mrs. Jones called in her family physician to attend her for her complaints of a dull pain in her arm. The doctor examined her, decided the trouble was muscular rheumatism and wrote out the following signed prescription: "Strontium Salicylate four ounces (Wyatt), teaspoonful in water four times a day." A relative of the patient took this prescription to a drug store at about noon and left the same with a drug clerk who told him to call later for it. He stopped by in the afternoon and the medicine was not ready. It actually was delivered to the patient's relative in the early evening, and a dose of the medicine was promptly taken by the patient. She soon became very sleepy and went to bed. During the night she was given three additional doses and she went into a state of coma. Her breathing became slow and labored, and her pulse slow. The next morning, when her doctor called, he realized something had gone wrong and he undertook to eliminate the drug from her body. She remained unconscious for about two days, and when she did improve she went through a severe and prolonged siege of disorders and distresses of her entire system.

It was ascertained, and not denied by the druggists, that the medicine that had been put up consisted of pure strontium salicylate, manufactured by Parke-Davis & Company, and that the patient had taken into her system within sixteen hours about seven hundred and twenty grains of the

Suit was instituted by the woman to recover large damages against the drug company, charging it with having negligently or improperly filled the prescription. The case went to trial and a verdict was found by the jury in favor of the plaintiff and against the drug company.

Upon the trial, the testimony indicated that the substance strontium salicylate, of which seven hundred and twenty grains had been taken in so

short a time, is dangerous in doses of more than about sixty grains a day. The drug, according to the testimony, is a combination including salicylic acid which is used as a corn cure by application so it will eat away the tissue of the corn and soften it. The testimony was that the prescription as filled would irritate the stomach and intestines, cause ringing in the ears, disturb vision, cause dilation of blood vessels and inflammation of the kidneys, and other dangerous effects, and that even death could be produced by it.

Upon the trial, the testimony centered upon what was the proper handling by a competent druggist of a prescription worded as the one in question. The doctor had put after the drug required the word "(Wyatt)," which word may have been intended as a reference to John Wyeth & Brother, the well-known pharmaceutical manufacturing company. According to the evidence, neither the Wyeth company nor any of the other well-known manufacturing chemists, except Parke-Davis & Company, put pure strontium sali-cylate upon the market. The Wyeth company, however, did put out a certain effervescent strontium salicylate compound, composed of about 10 per cent of that drug. According to the testimony, a teaspoonful of the Parke-Davis product was ten or twelve times as powerful as the Wyeth compound.

The defense of the case was conducted on the theory that it was necessary to fill a prescription literally and that that had been done in this case. On cross-examination, however, the defendant's own witnesses made clear that a careful pharmacist would have found it impossible to fill such a prescription accurately without consulting the doctor who made it out, to check the meaning of the word "Wyatt." One of the defense witnesses, when asked what he understood "Wyatt" in a prescription to mean, answered, "Well, I would say it would mean John Wyeth & Bro. or Sons."

The examination continued as follows:

"Q. If you were filling this prescription wouldn't you

"A. Surely.

"Q. You would find out?

"Ã. Yes.

"Q. And if you found that this effervescent strontium salicylate was the only one made by Wyeth and this prescription contains strontium salicylate Wyatt, there might be a contains might be a question in your mind as to whether this was called for or something else?

"A. Well, there is a question in every prescription.

"Q. There is a question in every prescription?

"A. Yes.

"Q. Why is there a question in every prescription?

"A. Sometimes it isn't definitely written or definitely prescribed.

"Q. When you can't read a prescription correctly you take chances and consult the pharmacopoeia to see?

"A. If we can't read it correctly we call the doctor.

"Q. Is there a strontium salicylate Wyatt?

"A. No.

"Q. There is not. Then it couldn't be filled according to the prescription?

"A. The manufacturer doesn't-

"O. It could not be filled according to the prescription?

"A. Say so, if you want to.

"O. This calls for strontium salicylate manufactured by Wyatt?

"A. There isn't such a manufacturer according to the spelling of the prescription there.

"Q. If you received this prescription over the desk in your drug store you would know what was meant by that, wouldn't you?

"A. Not necessarily."

Another of the defense witnesses on cross-examination gave the following testimony:

"Q. Suppose that prescription came to you, what would you take the word (Wyatt) to mean?

"A. Probably meant Wyeth.

"Q. Wyeth & Bro.?

"A. Wyeth & Bro.

"Q. Pharmaceutical manufacturers, are they?

"A. Yes, sir.

"Q. That is what you would take it for, wouldn't you? "A. Yes, sir,

"Q. Have you a right when a doctor prescribes a particular kind of drug, when you find the doctor has made a mistake, to substitute something else in place of that? "A. No."

From the judgment of the trial court, the deiendant drug company took an appeal and the higher court affirmed the judgment of the trial court, holding that liability was properly imposed upon the defendant. In its opinion the appellate court considered the theory of the defense in part as follows:

"The defendant contends that 'the legal duty of a druggiven to a purchaser can go no further than to dispense the identical substance which his prescription calls for.' No authority is cited by the defendant in support of this contention. In its brief it states: "We have searched the books and have been unable to find a case similar to the one at bar.' The instant contention is primarily based inpon the assumption that a pharmacist is obliged to fill any and all prescriptions. Such is not the law. As a

chemist he may know that the physician has erred in his prescription and that to fill it might cause death or serious injury to the patient. The argument interposed, briefly stated, is this, that the proof shows that there was no such pharmaceutical manufacturer as Wyatt, and that therefore Z who filled the prescription had the right to disregard the word 'Wyatt' and to fill the prescription with pure strontium salicylate. It would be a sufficient answer to this contention to say that the jury were fully warranted, under all the evidence in this case, in finding that a competent and careful pharmacist would have understood what was meant by the word 'Wyatt'."

The court further said:

"If a prescription is doubtful as to what drug is really intended, it is the duty of the pharmacist to be alert to avoid a mistake, and if there is any reasonable doubt as to the identical thing ordered it is his duty to take all one thing when another is called for. A contrary rule would tend to make a pharmacy a menace, instead of an aid, to suffering humanity."

In reading its conclusion to affirm the judgment against the drug company, the court quoted as follows from an earlier case, as a summary of the rules governing a druggist's liability for negligence:

"Finally, in applying his knowledge and exercising care and diligence, the druggist is bound to give his patrons the benefit of his best judgment; for even in pharmacy there is a class of cases in which judgment and discretion must or may be exercised. The druggist is not necessarily responsible for the results of an error of judgment which is reconcilable and consistent with the exercise of ordinary skill and care. He does not absolutely guarantee that no error shall ever be committed in the discharge of his duties. It is conceivable that there might be an error or mistake on the part of a qualified druggist which would not be held actionable negligence. But, while, as has been seen, the legal measure of the duty of druggists toward their patrons, as in all other relations of life, is must not be forgotten that it is 'ordinary care', yet it reference to that special and constitution of the special and constitutions. properly expressed by the phrase 'ordinary care,' reference to that special and peculiar business. In determining what degree of prudence, vigilance and thought-fulness will fill the requirements of 'ordinary care' in compounding medicines and filling prescriptions, it is necessary to consider the potential necessary to consider the poisonous character of so many of the drugs with which the apothecary deals and the grave and fatal consequences which may follow the want of due care. In such a case 'ordinary care' calls for a degree of vigilance and prudence commensurate with the dangers involved. The general customer ordinarily has no definite knowledge concerning the numerous medicines and poisons specified in the U. S. Dispensatory and Pharmacopoeia which registered apothecaries are by our statutes expressly allowed to keep, but must rely implicitly upon the druggist who holds himself out as one having the peculiar learning and skill and conceptions of legal duty necessary to a safe and proper discharge of that duty. 'Ordinary care' with reference to the business of the druggist must therefore be held to signify the highest practicable degree of prudence, thoughtfulness and vigilance and the most exact and reliable safeguards consistent with the reasonable conduct of the business, in order that human life may not consistently be exposed to the danger flowing from the substitution of deadly poisons for harmless medicine."

ALLEGED INJURY TO TOOTH DURING TONSILLECTOMY

A physician who specialized in ear, nose and throat work was consulted by a young man, complaining of throat trouble. About two years before the doctor had opened a peritonsillar abscess for the same patient. An examination of the patient revealed that the patient was suffering from hypertrophied and diseased tonsils and the doctor advised their removal. A few days later the patient entered the hospital for the purpose of the operation. Another physician was called in to administer a general anesthetic to the patient. The anesthetist inserted a Jennings' metal mouth gag in the patient's mouth which held the mouth open about one and one-half inches in order that the operation might be performed. The tonsils were removed uneventfully by the operating surgeon and the operation seemed to be in all respects uneventful. The patient remained in the hospital over night and the following morning the physician examined him and found his condition to be excellent and allowed him to return to his home. About a week after the operation the doctor again examined the patient and found his throat healing very well. The man had no complaints at that

time. However, about a month later the patient returned to the doctor's office and complained that a certain false tooth in his bridge work had become loosened by reason of the operation. He demanded money from the doctor for the purpose of having new dental work done and the doctor refused to comply with his request.

A suit was thereafter brought against the surgeon, charging him with negligently applying an iron brace in the plaintiff's mouth with the result that one of his teeth became loosened and his upper gums became abscessed, diseased and infected, necessitating dental treatment and causing him other injuries. The plaintiff claimed that he had been incapacitated by reason of the alleged negligence for a period of about a month and had lost a large amount of earnings.

The case was brought on for trial before a judge and jury and after all the evidence had been introduced on behalf of the plaintiff and the defendant the court submitted the issues to the jury and the jury returned a verdict in favor of the defendant doctor. The court denied the plaintiff's motion to set aside the verdict.

BROKEN ASPIRATING NEEDLE

A general practitioner was called to the home of an 18 year old girl and found her in bed, suffering from a cough. He prescribed certain medication and about a week later he recognized symptoms of fluid in her chest and decided to aspirate for diagnostic purposes. He caused the patient to get out of bed and sit on a chair. After having sterilized an area between the seventh and eighth ribs he inserted a hypodermic needle of heavy gauge between said ribs. Just at that moment the patient coughed and the needle broke at the hub. She had been warned beforehand not to move. The doctor immediately attempted to recover the needle but was unable to locate it, so he took the patient to the hospital in his car and had x-rays taken which showed the presence of the needle.

A surgeon on the staff of the hospital made an a incision at the place the needle had been inserted

druչ Suı. large da. ing it with . the prescription verdict was found plaint d against ial, the mii sanc only grains and probed, but was unable to locate it. After waiting a short time the surgeon obtained the assistance of a fluoroscopic expert and with the aid of the fluoroscope the surgeon recovered the needle. The patient remained in the hospital for a few days and returned to her home without any complications. The general practitioner never saw the patient thereafter.

A suit was thereafter instituted against the general practitioner, charging him with malpractice in connection with the breaking of the needle.

The case came on for trial before a judge sitting without a jury and at the close of the plaintiff's case a motion was made by counsel for the doctor to dismiss the complaint on the ground that the plaintiff had failed to prove a cause of action against the doctor. The motion was granted.

NOTES NEWS

SURVEY OF MEDICAL SERVICE AND HEALTH AGENCIES OF MICHIGAN

A special committee of the Michigan State Medical Society, authorized by the House of Delegates on September 22, 1931, to study the medical service and health agencies of Michigan, issued its report in a volume of 200 pages in June, 1933. This report was considered on July 12 by the House of Delegates assembled in a special meeting whose stenographic minutes fill ten pages of the Journal of the Society of August, 1933.

The movement which resulted in the survey seems to have been initiated on May 19, 1931 at a meeting of the Council of the State Society at which the representatives of five public health agencies gave detailed reports of the activities of their organizations. (N. Y. STATE JOURNAL OF MEDICINE, Aug. 15, 1931, page 1056.)

On Scptember 22, 1931, the House of Delegates authorized the appointment of a special committee to investigate all the health organizations in Michigan, and to make its report at a special meeting of the House of Delegates within a few months. The resolution authorizing the committee enumerated 19 organizations and groups to be investigated, and also 15 other groups whose activities touched the practice of medicine. (N. Y. STATE JOURNAL OF MEDICINE, Dec. 1, 1931, page 1480.)

The Committee that was appointed met on December 2, 1931 and voted to seek funds from lay organizations in order to carry on its studies. (N. Y. STATE JOURNAL OF MEDICINE, Feb. 15.

1932, page 246.)

It was evidently the intention of the House of Delegates that the special committee should complete its studies and make its report to a special meeting of the House of Delegates within a few months. The House, in fact, met on January 22, 1932, but its proceedings were not published in the Michigan State Journal, nor its action reported, except that it expected the special committee to continue its studies and to report to the regular meeting of the House in September, 1932. (N. Y. STATE JOURNAL OF MEDICINE, May 15, 1932, page 638.)

The special committee soon found that the work to be done required an immense amount of time and coordination of efforts, and it therefore engaged Professor Nathan Sinai, Ph.D., of the Student Health Service and Department of Health and Hygiene, of the University of Michigan as Director of the Investigation. The committee then authorized a lengthy program and plan for the study. (N. Y. STATE JOURNAL OF MEDICINE, June 1, 1932, page 694.) Dr. Sinai was assisted by fifteen subcommittees composed

of thirty-seven representatives of the State Medical Society. There were therefore forty-four persons officially appointed to make the survey.

The cost of the survey was announced to the House of Delegates in itemized tables amounting to \$9,764.06, of which \$3,750.00 was the salary of

the Director.

THE REPORT

The report of the Special Committee is in twelve chapters, as follows:

The Evolution of Medical Care. A historical study of the development of medical practice generally, pages 1-7.

2. Geographic Features of Michigan, pages 8-14.

3. Population, Income, and Costs of Living, pages 15-28.

Illness, Its Incidence, Care, and Costs,

pages 29-45.
5. Physicians, Distribution and Practice, pages 46-68.

б. Physicians, Income, pages 69-77.

Hospitals, pages 78-89.

The University of Michigan Hospital (State controlled) pages 90-102.

9. Public Health, its organization state-wide

and locally, pages 103-129.

- 10. Miscellaneous reports, including the Detroit clinics, cancer, laboratories, tubereulosis, negroes, the indigent, and medical licensure, pages 131-159.
- 11. Summary, with 16 sub-headings, pages 160-169.
- 12. Conclusions and Recommendations, pages 170-174.

The Report gives one the impression that it reflects the point of view of its director rather than that of the practicing physicians. Its style and content are similar to those of the Report of the National Committee on the Costs of Medical Care; in fact, Chapter 4, on illness, is frankly stated to be an abstract of publication 26 of the National Committee.

Many of the definitions are those of an undergraduate college classroom. For exmaple, on page 29, an illness is defined as any disorder which either

- disables an individual one or more days; (a)
- (b) any experience for which medical service of any kind is received; or
 - (c) any condition, symptom, or disorder for

which drugs costing fifty cents or more are pur-

Another example is the definition of a hospital on page 78, in the first paragraph of Chapter 7, which reads:

"In the modern system of medicine the hospital is the concentration point of patients and the personnel and facilities for their care. hospital are 'beds.' The occupants are served through a combination of medical, social, and economic functions. Ideally, then, the hospital is a social institution, economically operated, to provide the benefits of science."

The table on page 45 is based on a study of a large group of patients, and compares the medical services received with those needed,—the need seemingly being availability regardless of the practical usefulness of the procedure to the particular patient. The implication of the table on page 45 is that patients are not receiving the services which they might expect their doctors to give. For example, the table gives the following details:

"Days of hospital care, received, 937; needed,

"Health examinations received, 81; needed, 941.

"Number of refractions or glasses received, 41; needed, 175.

"Special nursing of hospitalized patientscases receiving it, 180; needing it, 578.

"Patients receiving laboratory procedures, 71; needing them, 581."

However, the report has a special value in its study of the statistics regarding the geographic features, populations, physicians and hospitals throughout Michigan, and their comparison with conditions which are considered to be standard in other states.

The recommendations of the report are few and of a general nature, and are contained in the three closing pages of the report.

ACTION OF THE HOUSE OF DELEGATES

The House of Delegates received the report of the Special Committee in a special meeting whose proceedings were reported stenographically in the Journal of the Michigan State Medical Society of August, 1933, beginning on page 465. The House adopted the following resolution:

"Resolved, that the report of the Special Committee-be accepted; and that the Committee be discharged. And be it further

"Resolved, that a permanent committee of five on Medical Economics be appointed by the speakers, this committee to study this report—and report at the annual meeting (of the House of Delegates) on September 11, 1933."

The Speaker appointed the members of the Special Committee as the permanent committee on Medical Economics.

The House then took up the specific recommendations of the Special Committee, which embraced the following subjects:

- 1. Health insurance.
- 2. Indigents.
- 3. Subvention of medical services.
- 4. Public health.
- 5. University Hospital.

Health Insurance: The Special Committee had recommended that the general principle of health insurance be approved. The House voted the following resolution unanimously:

"Resolved, That the Committee on Medical Economics be directed to study, prepare and present for the consideration of the House of Delegates a plan or plans for health insurance, provided, however, that such a plan or plans shall be based upon the following policies:

"'(a) Free choice of physician by the insured; "'(b) The limitation of benefits to those of

medical service;

"'(c) The control of medical service benefits

by the profession; and
"'(d) The exclusion of individuals or organizations that might engage in health insurance for profit."

The Indigent: The House adopted the recommendation of the Special Committee regarding the care of indigents, as follows:

"'1. That the committee and the medical profession undertake the medical care of the indigent as a joint responsibility.

" '2. That the costs of medical care for the indigent be met through a contribution of funds by the community and a partial contribution of services by the medical profession.

"'3. That the community funds be used to compensate in part the physicians for services rendered to indigents and that such compensation be

in proportion to the amount of services provided.

"4. That the community centralize in one agency the social and economic appraisal of the individual's or family's right to such medical services.

"5. That the local committees on medical economics institute studies and develop plans in accordance with the above recommendations.

"6. That the State committee on medical economics analyze data pertaining to the costs of medical care for indigents and plans for providing service, and that these data be made available to local committees."

Subvention of Medical Scrvices: There was a long debate on the principle of subvention, or State aid, to local communities which are unable to secure adequate medical services, especially in times of epidemic or calamity. The Special Committee had recommended "The approval of the principles of subvention, through State or local funds, to assure reasonably adequate medical care

for residents in the sparsely settled areas, and reasonably adequate incomes and facilities for medical personnel" This recommendation was adopted with the added words "Wherever and whenever it is approved by the local county medical society

Public Health The recommendations of the Special Committee favoring county health departments and State aid for them, were adopted

The University Hospital There was a brief dis cussion on the State Hospital of the University of Michigan, and the recommendation was carried that the authorites use the hospital for teaching purposes only

The House adjourned after authorizing the newly appointed committee on economics to report to the regular meeting of the House on September 11, 1933

INTER-STATE POST GRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

One of the most practical, interesting and extensive of medical meetings is that of the Inter-State Post Graduate Medical Association of North America which will hold its annual assembly on October 16 20, 1933, in Cleveland, Ohio Association was founded about ten years ago by a number of national medical leaders, among them Dr William J Mayo, the present President Any physician is welcome at the meetings, and is en rolled a member for a fee of five dollars

The assemblies have been popular, about five thousand physicians attending each one number on the program is given to all the members who assemble in one large auditorium equipped with loud speakers Patients are brought on the platform and their conditions

demonstrated to the entire audience

The program is conducted on the uniform plan of a diagnostic clinic at eight o'clock in the morn mg, with a noon intermission, an afternoon session at one o'clock, consisting of addresses with a dinner intermission, and an evening series of addresses beginning at seven o'clock. The program of each session is varied, some addresses be ing on medicine, some on surgery, and some on the specialties So far as the programs are concerned, the physicians are considered to be a group of general practitioners who are interested in the broader lines of the specialties

New York City is well represented among the speakers among those already announced being Drs Harlow Brooks, John F Erdmann, Burton J Lee, Joseph F McCarthy, and John J Moor-

THIRD DISTRICT BRANCH

The twenty seventh annual meeting of the Third District Branch of the Medical Society of the State of New York, will be held on Tuesday, September 5, 1933, in the Catskill Mountain House, Haines Falls The program will be as follows, listed in standard time

10 A M County Presidents' Round Table, led by Dr C G Rossman, Hudson

"The Interpretation of Abdominal 11 A M Signs and Symptoms, a Practical Study of Visceral Neurology "-Illustrated Edward M Livingston, M D, New York City

12 M Luncheon Introduction of Guests

"Certain Forms of Increased Intra 2 P M cranial Pressure and Their Treatment "-Illus trated with lantern slides Gilbert Horrax M D Neurosurgical Department, Lahey Clinic, Boston, Mass

3 PM "Some Varieties of Delayed Speech in Cluldren"-Samuel T Orton, M D, New York City

The Catskill Mountain House is reached

By those from the north taking Route 23 A out of Catskill to Haines Falls, there turn right for 2⅓ mıles

By those from the south taking Route 32 from Kingston to Palenville, from there Route 23 A to Haines Falls and turn right

By those from the west taking Route 23 A at Prattsville and turning left at Haines Falls

SEVENTH DISTRICT BRANCH

The twenty seventh Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York will be held on Thursday

September 21, 1933, in the Strong Auditorium, on the River Campus of the University of Rochester, Rochester, N Y

The program is as follows, standard time: 10.30 A.M. "Effects of Breathing Dust with Especial Reference to Silicosis," Dr. Royd R. Sayers, Washington, D. C. Discussion by Dr. William S. McCann, Rochester, N. Y.

11.30 A.M. "The Mechanism and Clinical Interpretation of Jaundice," illustrated with lantern slides. Dr. Chas. Gordon Heyd, New York City. Discussion by Dr. Alfred K. Bates, Auburn, N. Y.

12.30 to 1 P.M. Short business meeting and

remarks by Officers of the State Society.

1 to 2 PM. Luncheon (\$.75) at Todd Union, the dining hall adjoining Strong Auditorium.

The State Institute for Malignant Disease in

Buffalo, will stage an exhibit for the day in the Hall at the entrance of the meeting place.

2 P.M. "Diagnosis of Pulmonary Tuberculosis," Dr. Byrl R. Kirklin, Rochester, Minn. Discussion by Dr. Sol. C. Davidson, Rochester, N. Y.

3 P.M. "Medical Ophthalmoscopy, the connecting Link between the Physician and the Specialist," Dr. Arthur J. Bedell, Albany, N. Y. Discussion by Dr. Albert C. Snell, Rochester. N. Y.

"Bacteriophage in Wound Treat-4 P.M. ment," Dr. Fred H. Albee, New York City. Discussion by Dr. Edward T. Wentworth, Rochester,

THE PUBLIC RELATIONS OF MEDICINE

Abstract of an address given to the fourth year students of each of the nine medical schools of New York State between March 21 and May 16, 1933, by William H. Ross, M.D., under the auspices of the Committee on Public Relations of the Medical Society of the State of New York.

Scientific knowledge alone will not enable you to cope with all the problems which will confront you as practicing physicians. practice of medicine has been profoundly affected by the rapid evolution in sociology and economics during the last decade or two, so that personal health is considered in practically every plan for the improvement of society. The practicing profession is under an obligation to assert its leadership in all the plans for bringing all forms of medical service within reach of all classes of people. The medical school will teach you to recognize diseases and to prescribe for abnormal conditions of the body; but the ability of the people to carry out your directions will depend largely on the impersonal attitude of government officials, civic groups, and the people generally. The civic-mindedness, which is characteristic of the present year, is reflected in the numberless plans for making medical service available to all persons at all times, the most radical of which is that the government shall provide medical service for all its citizens, and that every doctor shall be the salaried servant of the state. You should be informed regarding your future relations to the newer movements in the practice of medicine, and be prepared to direct the development and evolution of the modern methods of practice.

The activities of health departments and voluntary health and welfare organizations, the increasing enactment of laws affecting the practice of medicine and the relation of the physician to public welfare, workmen's compensation, and the changing methods of medical service in industry, have caused economic problems for the physician which will increasingly need the leadership of medical organization for proper solution.

The State Society carries on constructive activity in its relations to public problems. It forms contacts with governmental and lay organizations working in the health field with the purpose of establishing cooperative and harmonious activities under the leadership of the profession. It is probable that there is a more satisfactory working relationship between the medical profession on the one hand, and departments of the state government and lay

organizations on the other, than ever before. The State Society has a legal department

which defends its members in lawsuits for alleged malpractice. It studies the subject

You are entering the practice of medicine at a time when the people are educated regarding what to expect in the way of disease prevention, and what the duties of government officials and the public are in the distribution of efficient medical services to all who need it.

The people have also been educated regarding the costs of sickness, and the inequality of the financial burden which it imposes. You will be expected, or compelled, to take action regarding the many health insurance schemes which are proposed.

The State Medical Society is a great school of medicine which you will soon enter for life. You should know what the Medical Society of

the State of New York is doing.

The State Society carries on graduate education under the joint administration of its Public Health Committee and the County Societies of the State. One of the recent reports of the Public Health Committee said that in the continuous education of the practicing physician, organized medicine makes its greatest single contribution. This service is now brought to the doctor in his own locality through his county medical society.

of medical economics and seeks to establish a system for the delivery of medical services on the principle that what is best for all the

people is best for physicians also.

The State Society maintains a Legislative Bureau to protect the science of medicine against legislation harmful to medical progress, to protect the public against untrained practitioners, to establish a desirable relation to health activitics administered by the state, and to mect constructively whatever problems of medical service depend upon legislative action.

Preparation for your future careers will be advanced by your becoming familiar with medical society meetings. They will continue your education and keep you informed of important problems in medicine, such as medical care, the trends in medical practice, the changing character of practice, proposals to meet the sickness problem, and the "public aspects of

medicine.

The great progress, however, in medicine carries with it profound changes in its application. Great socio-economic change carries with it great medical needs. It is necessary to be more than just a good doctor nowadays. The profession of medicine will always live up to its traditions of medical scrvice, but more and more it will have to take part in the ever widening public responsibilities of medicine which arouse public interest.

When the time comes to join your influent to that of other physicians, you should seemembership in your County Society. To this just speak to any member that you hapen to know, give him your qualifications, as he will give you a blank application; then give endorsement of two physicians, and trest will be attended to for you. There is difficulty for a well qualified physician will live up to the ethics of medicine in becoming a member of a county medical societ Membership in a county society automatica carries with it membership in the State Societ of which the county society is a constituent pa and it also carries with it membership in the Association.

American Medical Association. The profession looks to you to use yo idealism, your energy, your vitality, and your s perior training in the science of medicine to me the increasing responsibilities of the profession medicine in dealing soundly with the med cal problems of present day society. In all t modern efforts to solve the problems of me cine, the profession supports those whi improve human welfare. If human activity like a game in which the player receives t ball, keeps it or advances its position, as then passes it to the next player, the game the practice of medicine will soon be in yo hands for you to carry on the ideals, and expand the services of the profession mcdicine.

THE SARATOGA SPRINGS DEVELOPMENT

The laying of the cornerstone of the Hall of Springs at Geyser Park on July 12, 1933, marked the beginning of the final stage in the development of the great health resort at Saratoga Springs by the State of New York. The exerciscs began with a luncheon sponsored by the Saratoga Springs Rotary Club, at which special mention was made of the work of Dr. Simon Baruch who promoted the initial effort in the development of the spa twenty-three years ago, and whose son, Mr. Bernard M. Baruch, laid the cornerstone of the new building.

The principal address was made by Governor Herbert H. Lehman, who spoke of the peculiar interest of the State of New York in the development of the spa, and of its future services to those with arthritic diseases and

cardio-vascular conditions.

The Hall of Springs is the first of the latest group of physical evidences of the spa development. A complete research laboratory and an administration building are already under construction. The third and most impressive

structure, a hotel-sanatorium, made possibly the recent loan of the Reconstructive Finance Corporation of \$3,200,000, will conplete this monumental group embraced in the program for the new spa. Included with the buildings will be an outdoor gymnasium wis swimming pools, tennis courts, golf courses scientific design for therapeutic and recretional use, together with a bottling plant the will bring the minimum distribution of Geyst Hathorn and Coesa waters to 400,000 cases, 1,200,000 gallons of mineral spring water pyear.

The State has a capital investment at Sar toga Springs of \$5,500,000, which includes the Washington and Lincoln Bath Houses now operation, with a daily capacity of 5,000 tree

ments.

The official committee of physicians appointed by the Governor to cooperate with the Sarator Springs Commission consists of Dr. John Wykoff, New York, Dr. L. Whittington Gorhan Albany, and Dr. G. Scott Towne, Sarator Springs.

THE DAILY PRESS

SUBWAY NOISE

The New York City Subways are perhaps the noisiest places in New York City, and certainly the most annoying; but the railroad officials are developing a car that excludes noise; as is told in the following item in the New York Herald Tribune of August 16:

"Commissioner Wynne's Noise Abatement Commission, appointed several years ago, found that three-fourths of the unpleasant noises in the city were caused by speeding subway trains.

"The first noiseproof subway car, recently developed by engineers of the I. R. T., made a test run over the Lexington-Fourth Avenue Line yesterday morning, carrying officials of the company, Dr. Shirley W. Wynne, Commissioner of Health, and a group of newspaper and camera men as passengers. The car, its windows tightly shut, doors closed and cracks sealed, was ventilated by seven noise-eliminating exhaust fans, which reduced mechanical sounds by 99 per cent. It rolled over switch points, around curves and through normally noisy sections of the tunnel with all the ease and silence of a new Pullman car.

"The mechanical details of the noiseproof installation are relatively simple. The seven exhaust fans, each with a capacity for moving 714 cubic feet of air a minute, are fitted at intervals of about six feet along the roof of the car. Five are in the car proper and two in the vestibules. Four

fans operate at all times, while the rest are controlled by a load switch, automatically going on when the number of pasengers in the car increases. The four regular evaporation fans force the fresh air downward to the level of the passengers.

"In principal the chambers through which new air is drawn into the car are similar to the mufflers used in automobiles, but details of construction differ. The vents are covered with baffle plates, and the air passes through several acoustic chambers and many yards of pipe before it finally is admitted to the car. This filters out most of the noises from the tunnel.

"Mr. Murray said that the air in the subways, although the fact is not generally known, is much purer than street air. Since the air in noiseless cars is 155 per cent purer than regular subway air, he figures that the public will not oppose the plan to make all cars in the system noiseless.

"Dr. Wynne, commenting on the car, said that he thought noiseless subway operation would be a great boon to the nervous systems of all traveling New Yorkers. He indicated that medical opinion regards sudden, loud noises as very dangerous to persons suffering from heart ailments and high blood pressure. Metrically, the sound in the noiseproof cars measures 61.50 decibels, only 1.5 decibles more than in the latest Pullmans."

GENERAL PRACTICE

The New York Sun of August 17 contains an editorial opinion which reflects the attitude of

many thoughtful citizens when it says:

"Two distinguished members of the medical profession have recently given medical students the same advice—to become general practitioners. Dr. William J. Mayo, returning from medical meetings in Europe, expressed the opinion that medical schools in the United States are now turning out too many graduates who desire to be specialists. In an address to pre-medical students at Wesleyan, Dr. J. F. Fulton of the Yale School of Medicine said:

"In most large cities today the heart specialist refuses to see anything but cardiac cases and is quite unable to cope, for example, with an epidemic. The general public have already rebelled against this state of affairs and are looking more and more for the man who will assume responsibility for their general health, in short, the old-

time general practitioner or, perhaps one should say, for the "new-time" general practitioner." "General practice still attracts able young phy-

"General practice still attracts able young physicians, in some cases by the easy lure of necessity, but not in sufficient numbers to give every community its quota. If medical students are to follow the advice given by Drs. Mayo and Fulton there will have to be a change, not only in the attitude of the public toward the profession but in the economic arrangements between society and the physician.

"Perhaps part of the change is already visible. The medical specialist is not inevitably a man who has learned more and more about less and less, but there is a growing conviction that too many physicians have withdrawn into a narrow field of activity and that the practice of medicine calls for a broader and more comprehensive responsibility on the part of a majority of practitioners of medi-

cine.'

INSURANCE FOR HOSPITAL CARE

The New York Sun of August 15 comments on hospitalization insurance as follows:

"In an effort to reduce the cost of hospital care, and to make it available for wage earners and office workers in New York city in the form of a health insurance plan, a committee of hospital superintendents and others studied similar schemes of operation. They drafted a plan for this city in which a non-profit corporation would solicit and arrange for membership among employees of New York business and industrial concerns. The workers who joined would authorize their employers to deduct \$10.80 a year from their pay, in monthly installments, which would entitle them to three weeks of semi-private hospital care, under treatment of their own physician. Hospitals enrolled in this plan would admit patient members only on recommendation of personal physicians.

"This group plan cannot be put into effect, however, under the existing State insurance laws. Superintendent of Insurance Van Schaick has expressed his sympathy with the object of group payment schemes for hospital care, but has ruled that the law must be amended either to exempt such plans or to provide for their supervision by

the State. The sponsors of the plan in question intend to introduce at the next regular session of the Legislature a bill opening the way to its operation.

"The experimental nature of group payment plans for medical care, especially in large cities where they would not be restricted to any one industry or company, justifies caution in their enactment and suggests the desirability of close study. The committee on costs of medical care, of which Dr. Wilbur was chairman, included some discussion of these 'health insurance' plans in its report. Discussing voluntary health insurance, it pointed out that families with low or irregular incomes cannot usually be covered by this form of plan. They reported that voluntary health insurance has been succeeded by compulsory insurance in western Europe.

"In their comment several committee members urged 'the broadest sympathy toward experimentation in promising fields.' An insurance plan for hospital care in New York would obviously be an instance of such experiment, and its results would be likely to influence action on general health insurance schemes in other areas."

THE CULT OF PLUMPNESS

The time is at hand for the replacement of the cult of slimness, with that of plumpness, as was done in Turkey a generation ago. The change will come through the creators of fashions in clothes. Commenting on the change which is apparently coming, the New York Times of August 7 says editorially:

"The name of Dr. H. R. C. Rutherford should be known to all women struggling for slenderness—that is, to all women. Not that he would give them a prescription for going scrawny. In an address to the British Medical Association he said: 'I would emphasize the importance of rest and preach the gospel of fatness.' All his women patients will probably leave him, but let them wait a few months. He is on the side of the Paris fashion arbiters, who have fallen en masse, with the rest of Parisian femininity, for one of our plumper movie stars. The considerable curves, the large, dashing hats, the very jewels of this houri are being copied all over Paris. How long will it be before women are flocking to Dr. Rutherford or to physicians who agree with him?"

ALIEN DOCTORS IN GERMANY

The following item regarding the practice of medicine in Germany by alien doctors was carried by the New York Sun of August 15:

"German doctors were divided by official decree today into 'German and alien races' and were forbidden to exchange cases or to consult each other.

"The decree, issued by Medical Commissioner

Wagner, forbids German physicians to send cases to non-Aryans or to treat cases sent by non-Aryans. They are forbidden also to consult with non-Aryans.

"An official health insurance list will be published, it was announced, to enable insured persons to distinguish non-Aryans from German doctors.

BOOK REVIEWS

THE DUODENUM. Its Structure and Function, Its Discases and Their Medical and Surgical Treatment. By EDWARD L. KELLOGG, M.D. Large octavo of 855 pages, illustrated. New York, Paul B. Hoeber, Inc., 1933. Cloth, \$10.00. (Hoeber's Surgical Monographs.)

For twenty years Professor Kellogg has studied and written on duodenal problems. The present volume is the result of these years of study. It is the first American book upon this subject and may be considered authoritative. Its twenty-six chapters form a complete study of the subject. Evidently the study of duodenal problems has been a hobby with the author. His wealth of clinical experience adds to the readability and value of the book.

No better review of this work could be made than is comprised in the foreword to it by George David Stewart, that rare and lovable man. "The older surgeons will find it stimulating and practical, the younger will find that, and further, that it is time-saving. To look up this knowledge from the magazines today requires not only intelligence and industry but an amount of time at one's disposal, greater than most can command in this age of hurry, when there are 'no more spacious afternoons and when the clock never ticks slowly of a winter evening."

The original drawings for this volume were made from presidents in England and from material in the Heister.

The original drawings for this volume were made from specimens in England and from material in the United States. The wax casts by Thomas White of Harvard form part of the illustrations. The chapter on Physiology was reviewed by Professor A. C. Ivy of Northwestern University Medical School. Professor Bailey K. Ashford wrote the chapter on Parasitology. Professor A. Judson Quimby contributed the section on x-ray diagnosis. Professor F. M. Jeffries reviewed the text dealing with laboratory procedures.

The entire work is excellently written and illustrated. The book work is in the usual fine Hoeber style. There is a very extensive and valuable bibliography.

The book is recommended to the physician as well as to the surgeon.

Russell S. Fowler.

CRITERIA FOR THE CLASSIFICATION AND DIAGNOSIS OF HEART DISEASE. By JOSEPH H. BAINTON, M.D., ARTHUR C. DEGRAFF, M.D., ROBERT L. LEVY, M.D., and HAROLD E. B. PARDEE, M.D. Third Edition. 12mo of 131 pages, illustrated. New York, New York Tuberculosis and Health Association, 1932.

This useful little book in 66 pages defines in clinical language the 139 terms included in the American Heart Association's Nomenclature for Cardiac Diagnosis. It is a model of brevity but is comprchensive enough to assure a reasonable degree of uniformity in the use of these descriptive terms. The new edition is offered in order to include the recent additions to the nomenclature.

An appendix provides a practical guide to radiological diagnosis in heart disease, with diagrams illustrating shadow outlines in various common heart lesions, and a key for the interpretation of electrocardiograms. The latter gives 48 sample tracings, which include examples of all the well known electrocardiographic faults. It is interesting to note that since this section was distributed to members of the Association, the committee has decided to accept the so-called "new terminology" of bundle branch block, with the left axis deviation denoting left bundle branch block, the other criteria being met, instead of leaving the question unsettled.

THE HARVEY LECTURES. Delivered Under the Auspices of The Harvey Society of New York, 1930-1931. Series 26. Octavo of 186 pages, illustrated. Baltimore, Williams & Wilkins Company, 1931. Cloth, \$4.00.

The female sex hormone is already beyond the realm of mystery. Dr. Frank of the Mt. Sinai Hospital has contributed no small part towards its solution and his argument is presented in simple language.

Able clinicians well realize that it is a fatal mistake to separate mental processes from physical ones and that we should at all times accept this permanent interrelationship. Modern medicine has often erred in emphasizing but one phase of this dual concept. One contributor discusses four common types of error to prove the importance of this principle. These may be summed up as tactlessness and lack of common sense or diplomacy.

It is interesting to read about immunological reactions of certain plants to specific fungi. In certain instances, such as the sugar cane, the mosaic disease will recur in regular cycles. Then again in other instances a plant disease may be exterminated by influencing the nutritional affinities of its specific offender.

The chapters on coronary thrombosis, tissue immunity and mass action in cerebral function should prove of equal interest.

EMANUEL KRIMSKY.

Hookworm Infection. By Clayton Lane, M.D. Octavo of 319 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$6.25.

A masterly treatise on this seourge of the tropies and subtropical regions. The zoology of the Anchylostoma, as well as the mode of infection, the clinical picture and the treatment are discussed most completely.

Notwithstanding the apparent remoteness of the subject to the majority of physicians the reviewer recommends this volume for study to one and all. It is exceptionally well written and leaves one with a feeling of literary and scientific satisfaction. Geo. Webb.

THE PELVIS IN OBSTETRICS. By JULIUS JARCHO, M.D. Octavo of 365 pages, illustrated. New York, Paul B. Hoeber, Inc., 1933. Cloth, \$6.00.

Its fine bibliography alone should make this book worth while. Devoted to pelvimetry and cephalometry, the author states that there has been no book in English covering these subjects in detail. Of doubtful praetical value, much space has been given over to tabulations of racial variations in normal pelves. The illustrations are admirable and helpful. The chapter on Roentgen ray pelvimetry is good, opening up the whole subject in a very practical way. It is interesting to note that the author, discussing external pelvimetry, states that it is his practice to make several readings, and strike an average. His new methods are better.

CHARLES A. GORDON.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 1, 43rd Series, 1933. Edited by Louis Hammann, M.D. Octavo of 305 pages, illustrated. Philadelphia, J. B. Lippineott Company [c. 1933]. Cloth, \$3.00.

This issue, the first under a new editorial staff, is ushered in with the ever-important problem of when to supplement a clinical examination with laboratory tests. The author takes the viewpoint that many laboratory measures undertaken in the wards are superfluous

1069 BOOKS

and reflect an incapacity to rely on one's own observations. He fortifies his stand by listing the indications for

the more important tests.

More recently certain workers have reported greater successes with gentian violet than with tannic acid for the treatment of burns. The method of application is

herein described in detail. Then there is a valuable article on the uses and limitations of radium therapy. The practitioner may profitably refer to the many conditions for which the writer specifically advises radium pro and con. In those conditions where radium is of value the writer is quite frank in advising the reader when any other agent is of even

more certain benefit.

Tuberculin therapy has managed to continue as a therapeutic weapon for tuberculosis of the eye. The basis for its survival for ocular use is more on empiricism than on actual fact. Ocular tuberculosis is not often a clear cut clinical condition and many of the supposed successes from its use are in reality allergic conditions which depend on a non-specific protein rather than on tuberculin to reap success. This the writer fails to mention.

There is a chapter on the progress of medicine and while we do not read of new recent discoveries we are reminded of something that is often far more important, namely, the intelligent usage of those medicaments which have not as yet established themselves too firmly.

Other chapters on familiar topics should find their practical interest for the physician. EMANUEL KRIMSKY.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgcry. Series 1932. Chicago, The Year Book Publishers [c. 1933]. General Therapeutics, edited by Bernard Fantus, M.D., and Louis B. Karloon, M.D. 12mo of 448 pages, illustrated. Cloth, \$2.25.

This issue as others in this series has its usual fill of interesting news-some of which are novel; others falling in the category of skepticism; still others revolutionary; a few contradictory; and some based on blind empiricism. Let us summarize just a few:

1. One writer submits evidence based on many tests to show that Pirquet-positives are much more resistant to tuberculosis than Pirquet-negatives. Not long ago it was taught that a Pirquet-positive in a young infant was usually of fatal significance.

 Desensitization for preventing anaphylactic shock by increasing fractional doses of serum is now regarded as a dangerous procedure. A substitute method is de-

- scribed.

 3. Bastedo still recommends colon irrigations for mucous colitis and gives detailed reasons which appear convincing. There is an article immediately following which flatly objects to colon irrigation. It is a sign of progress to read of free, individual expressions rather than of the "yes-man" policy so long oppressing medical thought.
- 4. Sterile mineral oil instillations are found to exert soothing effect on painful lesions of the bladder.
- There are a number of valuable "Don'ts" for the physician to observe in the injection treatment of hemorrhoids.
- The injection treatment of hydrocele has gained considerable impetus of late and is winning increasing
- 7. Mercurochrome is again subject to scathing criticism for its inertness. For the layman it is still a 'reliable antiseptic."
- 8. A hacteriologist tells us that vaccines are of especial value in the treatment of sinusitis and otitis media. That of course is laboratory theory edia. That of course is laboratory theory.

 9. As was expected the BCG vaccine is becoming the
- subject of increasing controversy. The babies will continue to suffer as long as this controversy lasts and longer

10. During the recent polioniyelitis epidemic convalescent serum was endowed with curative properties. Now that it's over, its value is doubtful.

11. The controversy of the relative value of organic and inorganic iron is still alive. And when we humans fail to satisfy either school in our blood reactions, the

mice may be depended upon.

12. One writer has had gratifying results with ovarian therapy in cases of hemophilia. Others who use it will probably learn differently. As long as nobody will contradict this writer on paper it will continue to stand out as a recognized procedure or one "worthy of trial."

13. Foreign protein therapy for carbuncles is recom-mended unequivocally as a wonderful therapcutic measure superior to any other method. It sounds too

good to be true.

14. After due delay we already read of the Ether Treatment as being worthless and often harmful for whooping cough. One wonders why it was a treatment in the first place.

EMANUEL KRIMSKY. ment in the first place.

ROENTGENOGRAPHIC STUDIES OF THE URINARY SYSTEM. BY WILLIAM E. LOWER, M.D., and BERNARD H. NICHOLS, M.D. OCLAVO of 812 pages, illustrated. St. Lonis, C. V. Mosby Company, 1933. Cloth, \$16.00.

This single-volume work of some eight hundred pages represents a valuable contribution to the study of Uro-logical Roentgenology. The major portion of it is de-voted to cystography, ureterography and pyelography based upon individual cases giving the history, x-ray findings and films. It is really more of an encyclopedia of case records which include practically all lesions.

The first few chapters are devoted to the technique

of urographic study, as applied to each portion of the genito-urinary tract. The authors emphatically stress the need for complete cooperation of the urologist and radiologist in considering the clinical data together with

the study of films.

The reviewer is pleased to note the presentation of the many variations of the so-called normal, as well as the many and varied anomalous deviations. These are particularly essential to a working-knowledge of clini-cal interpretation. The history and bibliography are purposely omitted. The authors recommend the radiographic study of gross specimens removed at opera-Augustus Harris.

DISEASES OF THE HEART. By SIR THOMAS LEWIS, M.D. Octavo of 297 pages, illustrated. New York, The Maemillan Company, 1933. Cloth, \$3.50.

The work of Thomas Lewis is known to American students of cardiac problems as that of a pioneer investigator. This book introduces him to a much wider circle in the role of a master clinician. It is an eminently practical work which can be consulted and utilized by the general practitioner in his daily rounds. Here he will find his problems discussed with the same clear vision and logic-that is the same scientific attitudethat is evident in the author's reasearch publications. This provides as sound a basis for practice as is obtainable. No references are quoted and no disputed points are discussed beyond a statement that they are in doubt and the explanation that seems the most acceptable in the light of present knowledge. The small amount of space devoted to the electrocardiograph is significant. This instrument is of great value occasionally, and of some help many times but it is of minor importance in practice, however valuable it is as an aid to research.

Lewis has probably pushed the frontiers of cardiology further into the unknown than any student since Mac-kenzie. He returns to Mackenzie in emphasizing the predominating importance of cardiac function over cardiac morphology from the standpoint of the doctor. book is a simple and sound guide to cardiae practice.

OUR NEIGHBORS

MEDICAL ECONOMICS IN PENNSYLVANIA

The Philadelphia County Medical Society met on May 17 and discussed Medical Economics, particularly the reports of eleven subcommittees of the Committee on Economics. These reports fill nine pages of the June issue of the Pennsylvania Medical Journal, and were on the following subjects:

1. Contract Practice. The report states a general principle.

"In general, it may be said that any plan by which a financial profit is made from medical services by an individual or agency other than the physician is unethical; and is, therefore, not only unfair to the physician but is inimical to the best interests of the public. It may be said further that many contract schemes not only exploit the physician practicing under the contract, but also force him to enter into unfair competition with his fellow practitioners. To protect the public and to prevent exploitation of the physician, it is recommended:

"That the President and Board of Directors of The Philadelphia County Medical Society appoint a Medical Court of 6 members, 3 from the Board of Directors and 3 from the membership at large, each to serve 3 years, 2 to be appointed annually, 1 from the Board of Directors and 1 from the membership at large. The duties of this Court shall be to examine all existing medical contracts between any member of the Society and an intermediatory to determine whether the principles mentioned

above are being infringed.

"That since exceedingly unfair contracts are now in force between several hospitals in Philadelphia and the Board of Education, wherein the lay Boards of Trustees of those hospitals, without consulting the physicians and surgeons on the staff, have contracted to give free medical and surgical treatment to teachers and other employees of the Board of Education upon the payment of a room endowment fee to the hospital, it is recommended that the County Medical Society investigate this glaring example of unethical contract practice and urge immediate abrogation of every contract of this type."

2. Prescribing and Dispensing Practice. The report says:

"Physicians should prescribe and recommend, as far as is possible, products included in the U.S.P., the National Formulary, and in New and Nonofficial Remedies.

"Physicians should familiarize themselves

with the proprietary names and nonproprietary equivalents, as well as with the relative cost of commonly used remedies.

"We recommend full cooperation with and confidence in the conscientious pharmacist who has no desire to exploit patent medicines or to encourage self-medication, much preferring to preserve his ethical professional status.

"The practice of hospitals that sell medicine to charity patients for a profit is condemned.

to charity patients for a profit is condemned. "Exploitation of the practice of medicine through direct advertising to the laity by pharmaceutical manufacturers must be discouraged. This aim can be achieved by refusing to prescribe preparations so advertised and by ceasing to distribute to patients samples of controlled products distributed for that purpose by detail men. A consciousness of our own superiority in medical education should protect us from our human gullibility."

3. Dispensary Abuses and Social Service Departments. The recommendations are as follows:

"As the dispensary of any hospital is a place for the efficient treatment of the deserving sick-poor, except for emergencies, none but this class of patients should be admitted at any time. Our city possesses a sufficient number of indigent sick at all times to tax the facilities and professional staffs of every dispensary without treating patients, who are able to pay for medical service, in free dispensaries.

"To avoid exploitation of the indigent, the drug departments in hospitals should be regulated so that prescriptions are dispensed at

"Another abuse is the hospital optical department. There is no excuse for the maintenance of an optical department in any hospital. Every hospital conducting such a department is unethical; and all, with the exception of the Pennsylvania Hospital, show a decided profit from the sale of glasses. This profit pays for the maintenance of the department, the salary of one or more refractionists, a clerk, and a fee to the optician who provides the glasses and fits them to the patient.

"Any doctor not licensed to practice in the State of Pennsylvania, who is employed by any hospital dispensary and paid a salary for his work, should immediately be dismissed, and a "regular" appointed to fill the vacancy. The practice of medicine by unlicensed and unregistered physicians is contrary to the law of

(Continued on page 1072-adv. xii)

ANTISEPTIC ANALGESIC ASTRINGENT

WYANOIDS

FOR

HEMORRHOIDS

In addition to the special shape—easily inserted—forced upward and held in place automatically, the actual size of WYANOIDS is worthy of note.

WYANOIDS are thirty-five per cent larger than the average bullet or cone-shape rectal suppository—and afford the patient more pro-

longed medication. A greater coating of the rectal canal by the cocoa butter—an increased area contacted by the Zinc Oxide, Boric Acid, and Bismuth Oxylodide (which contains about 6% iodine) a more prolonged Ephedrine effect.

Thus the lubricating, antiseptic and analgesic effects of this well balanced formula are increased by the size of the suppository.

WYANOIDS are packed twelve in a box, with a loose dispensing label.

A diagnostic record chart has been prepared for use in proctologic work. May we send you a supply?

the State of Pennsylvania, and if necessary, the law should be invoked.

"Hospitals should be compelled to comply with any regulations for dispensary management adopted by The Philadelphia County Medical Society, which are equitable to the patient, the hospital, and the doctor.

"The basic function of the Social Service Department of the hospital is to aid in assigning the patient to the proper department in the hospital, and to follow up the case after discharged from the hospital in order that the recommended treatment may be carried out. Because of the activity of lay boards of many of our hospitals to conserve expense, the Social Service Department in many hospitals has degenerated into a clerical force concerned chiefly with the collection of fees from the patients on admission. The staffs of our hospitals rarely show any interest in the social service department. It is therefore recommended that they become familiar with the working of this department in order, by intelligently directing its work, to restore it once more to its proper function. Eventually supervision of the Social Service Department should be removed from the lay board and returned to the medical staff where it belongs.

"A list of reputable physicians in each neighborhood of the city, who are willing to assume treatment of patients on their discharge from the hospital, should be furnished to the Social Service Department of each hospital.

"The public should be informed that doctors are not paid for their services in wards and dispensaries of hospitals. Many laymen have the erroneous impression that doctors are well paid for this work, therefore have no hesitancy, not only in asking but in demanding free service. Many also believe that because they have contributed to one of the welfare agencies, they may demand free treatment in any hospital, because the welfare contributes to the maintenance of the hospital. They believe that such contribution places them in a preferred class.

"It is the desire of every physician to give to the public the best possible medical care, but the cost of the care of the indigent must not fall upon the doctor. It must be met by civic or other agencies, so that in due time physicians who are now giving their services free to hospitals for the care of the indigent will be compensated for this service."

4. Encroachment of Lay Workers on the Professional Field.

The groups to which this report refers include the following:

(a) Untrained charity workers.

(Continued on page 1074—adv. xiv)

DURING PREGNANCY AND THE POSTPARTUM PERIOD

supporting treatment is essential. Fellows' Syrup is the most logically prepared tonic at the disposal of the physician.

It contains all the required minerals in correct proportion and in an easily assimilable form. These are Manganese and Iron to renew the blood stream impoverished by continued loss; Calcium to replenish the constant calcium depletion; Potassium, Sodium, and Phosphorus to overcome the neural depression; Strychnine as a tonic to cell metabolism; and Quinine as a gastric stimulant.

There is no better tonic than Fellows' Syrup to the parturient and post-parturient patient. During these trying periods, the suggested dose is one teaspoonful three times daily well mixed with water.

(b) Unskilled laboratory assistants.

(c) Visiting nurses and nurse anesthetists. The recommendations are—

"That all hospitals be advised that the practice of allowing any lay person to give medical advice while aiding in social service, vocational work, etc., be discontinued.

"That a committee of this Society be formed to investigate all medical laboratories, both hospital and privately conducted, the investigation to include both the laboratory director and the personnel of each, to the end that the work shall be done by qualified persons.

"That this committee consult with the medical schools in an endeavor to obtain more ample instruction in all its phases, both theoretical and practical, under qualified teachers, in anesthesia for the undergraduate medical student.

"That this committee visit and consult with the hospitals with the view of establishing a Department of Anesthesia in each hospital, this department to be under the direct charge and supervision of a trained medical anesthetist, the head of the department to have authority as such, and to be a member of the major staff."

5. Free Information Service to Insurance Companies. The basic recommendation is that fees should be paid physicians for all medical services to the companies.

6. Health Department Cooperation. The committee reports:

"Numerous people able to afford a moderate fee for the care of their children have become educated to go to the Health Centers for the following reasons: The solicitous form letters sent out to the laity by the Department of Public Health and other propaganda of the Health Department which have directed them into these channels.

"The failure of the school nurses and visiting nurses to remember the existence of a fam-

ily or neighborhood physician.

"The charge of prohibitive fees by many physicians and their failure to report promptly findings to the health authorities and to cooperate adequately with them.

"The committee recommends the adoption of a plan similar to the Detroit Plan, and the cooperation of the Health Department in educating their nurses and clinic workers to refer able-to-pay patients back to their family physicians for treatment.

"The discussion concerning the present unsettled question of the efficacy of scarlet fever The Department of Public immunization. Health intends to organize a city-wide cam-

paign for scarlet fever immunizations. A committee of pediatricians, appointed by The Philadelphia County Medical Society, is not favorable to this plan. This committee feels that scarlet fever immunization is still a moot question and should not be endorsed by The Philadelphia County Medical Society. On the other hand, the Department of Public Health is of the opinion that its experience in the City of Philadelphia justifies the inauguration of this campaign.

"The Committee recommends that the opposing pediatricians and officials of the Health Department should be invited to a round table conference at which the problem should be freely discussed and a final decision gracehold."

freely discussed and a final decision reached.

"Demonstrations by the Department of Public Health at The Philadelphia County Medical Society Building should be annually repeated for the purpose of demonstrating the approved methods of performing the Schick and Dick tests to the members of this society so that an approved system may be adopted.

"All new patients accepted for treatment at Health Centers should have a signed statement from their family physicians or neighborhood physicians substantiating their inability to pay a private physician for services rendered."

7. Hospital Abuses. The report says:

"This section recognizes that the major abuses in hospital administration occur in the dispensaries and social service departments, and this phase of medical economics has been thoroughly covered by the Committee on Dispensary Abuses.

"The Philadelphia County Medical Society should oppose the policy of all hospitals that engage in any form of contract practice with

any individual or corporation.

"Your committee believes that the publication by hospitals of lists of patients referred by its individual staff members, and in some instances the actual monetary returns to the hospital, is not in the best interest of a harmonious relationship between the hospital and its staff.

"Hospitals are charitable institutions which depend largely upon the public for their support. The public, however, rarely meets the hospital superintendents or other executives responsible for their management, but they do come in daily contact with reception clerks, telephone operators and desk clerks. Kindness courtesy and consideration on the part of these individuals in their relations with hospital visitors is just as essential as kindness and courtesy and consideration on the part of

(Continued on page 1076-adv. xvi)

(Continued from page 1075—adv. xv) the medical and nursing personnel to the patient."

8. Industrial Medicine. The committee discusses several points of workmen's compensation and says:

"The employment of physicians at fixed salaries either on part or full time. This, we believe, constitutes contract practice and falls in the group placed under the ethical ban by the American Medical Association, as defined in their specifications of contract practice.

"Insurance compensation clinics established for the treatment of employees of those insured under the Workmen's Compensation Act. These we believe are forms of contract practice and hence should be treated as such according to the standards of the American Medical Association."

9. Medical Representation on Hospital Boards. The report says:

"At present there is no uniform relationship between these groups in Philadelphia hospitals. These relations range from those that work well and in which all interests are represented to those which result in inefficiency and produce bad feeling. There is no disposition on the part of staff members in general to deny the right of the hospital Board to the last word in hospital management, but there is an almost universal demand that it should be made impossible for Boards to make medical appointments and to decide medical issues without obtaining the official opinions of the medical staffs. The recommendations of this Section apply to many different hospital set-ups, and must be subject to modification to meet individual conditions.

"The medical staffs of a hospital should have an easy and acceptable way to bring matters to the attention of the Board of Trustees.

"The medical staff should be informed of all Board recommendations on medical matters before final decision is made and put into effect"

10. Workmen's Compensation. The committee reports:

"The report of the Section on Workmen's Compensation embodies: (a) An agreement entered into between The Philadelphia County Medical Society and the Insurance Carriers; (b) a schedule of fees has been ratified; (c) a Board of Arbitration to be appointed for the settlement of all matters of controversy between members of The Philadelphia County Medical Society and the Insurance Carriers.

"It is important to note that under the terms of the agreement a general practitioner can

Support in Cases of OBESITY

ABDOMINAL walls, when flabby or pendulous, require the support of a physiological garment with a low-cupped, form-front for security. Uplift should be provided without raising the flesh unduly through the body center, but with a slight flattening effect. The Camp Physiological Support, with the Camp Patented Adjustment, illustrated (Model No. 39)) functions in this way without improper constriction or discomfort.

Figures at bottom of illustration show:
Left—Obese and prolapsed condition without support.
Right—Improved posture with flesh control and uplift from support.

Approved and recommended by leading physicians. Sold by Surgical, Drug and Department Stores and Corset Shops. Write for Physician's Manual.

treat his own case provided he is a member of The Philadelphia County Medical Society."

The report closed with a column of fees for a great variety of operations and treatments.

11. Coordination of Medical Service.

"Pay clinics were investigated and found to be of 2 kinds: (1) Pay clinics in Out-Patient Departments of the various hospitals accepting any fee from a few cents to several dollars for services rendered, the average being approximately 25 cents for a visit. This practice is widespread in the various dispensaries and would in no wise appear to jeopardize the private practice of medicine throughout the community, except in so far as patients are admitted to these clinics who could afford to be attended by private physicians. (2) Pay clinics organized for the purpose of diagnosis and continued treatment of patients able to afford the services of a private physician. So far as the committee is aware there is but one pay clinic in the city. While a great many patients are referred to this clinic by private physicians, others are accepted on personal application. The committee is cognizant of this situation and believes it would be possible to establish a more amicable relationship between the clinic and the private physicians involved.

"Modern hospitals are and should be diagnostic centers where the difficult cases which private physicians are unable adequately to care for can be studied and treated. Patients may be bedridden or ambulatory. All hospital staffs are groups of physicians organized in an institution in which detailed and specialized medical studies and diagnostic and therapeutic procedures are carried on. One of the major problems of the present committee is to clarify the relationship between group practice in hospitals and the private physicians not associated with these groups. When this relationship has been satisfactorily defined and is agreeable to all concerned, the principles thereby indicated should be steadily adhered to by hospital In-and-Out-Patient Departments in the care of free, ward, semiprivate, or private horizontal or vertical patients.

"This is a move to coordinate the medical activities within the profession. It would also seem desirable to coordinate the activities, interests, and aims of the various health organizations and councils in Philadelphia and bring their interests and activities into proper relationship with The Philadelphia County Medical Society. The duplication of effort which now exists, might be eliminated. The Committee on the Coordination of Medical Service is at

present moving to this end."

REDUCED FROM **PARTS** OF THE UNITED STATES AND CANADA RAILROAD RATES ALL

HOSPITAL AID IN WEST VIRGINIA

The August issue of the West Virginia Medical Journal contains the following editorial on State Aid for Hospitals, through the appropriation of \$25,000 by the Legislature:

"Any hospital (other than state hospitals) doing charity work within the State may file with the Board of Control itemized bills for all charity cases treated during the three months period ending October 1, 1933, and each three months period thereafter. Such bills are to be made out in the form prescribed by the Board of Control. Sixty days shall be allowed for the filing of such bills, after which time all bills shall be audited and scheduled for payment.

"If the aggregate of all claims filed exceeds one-fourth of the amount appropriated for the year, then the Board of Control shall apportion the one-fourth appropriation so that each claim

will receive its pro rata share. No claim shall be considered by the Board unless the Board has received notice from the hospital at the time of receiving the charity patient, said notice to be on forms prescribed by the Board. The Board is authorized to limit the number of charity cases that may be received in any one hospital and also to prescribe its own general rules and regulations regarding forms, methods of distribution and payment for services.

"The success of the administration of the present appropriation, as we see it, lies in the limitation of patients at each hospital by the board of control. Better still, we would like to see a limit of hospital days rather than a limit of patients. Otherwise the hospitals are liable to find themselves receiving only 25 to 50 cents per day for charity patients under the appropriation."

REFERENCE COMMITTEE IN SOUTH CAROLINA

The President's address at the House of Delegates of the South Carolina Medical Association on April 8, printed in the July Journal of the Association, contains the following proposition regarding a reference committee:

"Many times the work of this House of Dele-

gates has slowed up and has been unnecessarily prolonged. Dr. Hines has mentioned to me a plan which I believe will help in facilitating the work; that is, that we appoint a committee from our number here tonight which will serve as a

(Continued on page 1081-adv. xxi)

(Continued from page 1080-adv xr)

reference committee, any proposition proposed here to be submitted to this committee. The committee will retire and discuss it fully, then come back in here and give us their appraisal of it. Then the House will consider the matter and aet upon it, not necessarily taking the committee's appraisal, but acting upon it on its merits plan is followed in the American Medical Association and several state medical associations. Of course, if we met for several days it would have more value; but even meeting only one night as we do, we think it will be helpful. It is not proposed with the idea of making the meeting any less democratic, but to let these men study the propositions and give us the benefit of their opinion."

CERTIFICATION OF SPECIALISTS IN RHODE ISLAND

The July number of the Rhode Island Medical Journal records the following action taken by the House of Delegates of the Society on

May 18, 1933:

"Your Committee recommends that the President of the Rhode Island Medical Society appoint a Board of nine members, including the President, the first Vice-President and the Secretary ex-officio, whose duty it shall be to classify each and every member of this Society under the following headings:

1. General Practitioners

2 Internists

3. Pediatricians

4. Neurologists

5. General Surgeons

6 Orthopedists

7. Urologists

8 Gynecologists

9. Anesthetists

10 Eye, Ear, Nose and Throat Specialists

11. Roentgenologists

12 Obstetricians

13 Dermatologists

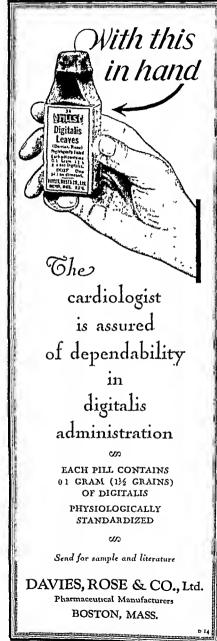

14. Pathologists

"This Board of Classification shall be empowered to formulate the standards for the classification

"It is recommended that the members of the Board of Classification be appointed as follows.

"Two for three years, two for two years, and two for one year and thereafter two each for three-year terms

"The Committee shall have full power to act, and its duties shall include classification and publication. It is further recommended that no member of your present Committee be appointed a member of the Board of Classifieation except the President and Secretary, who would be members ex-officio."

DENTAL SERVICE FOR DIABETICS

By HAROLD A. KENT, D.M.D., BOSTON, MASS.

Part of a Symposium on Denial Conditions as They Affect General Health, presented at the Annual Meeting of the Medical Society of the State of New York, at New York, on April 4, 1933.

During the past six years my assistant, Mrs. Clifford, and I have had the opportunity to examine the months of more than five thousand diabetic patients; we have also treated a substantial percentage, 50 per cent, of this number. The diabetic group provides a sat-isfactory field of study for the oral specialist, not alone because of the interesting clinical findings which have come to light, but also because they are one of the most cooperative groups of patients with whom the doctor comes in contact.

From the standpoint of clinical findings, some of my observations have been substantiated by Drs. Elliott P. Joslin, Howard Root and Priscilla White, who have cared for these patients at the New England Deaconcss Hospital; certain conclusions are derived from statistical calculations, as well. It is my hope that I may direct your attention to some new observations, which, in my opinion, warrant further study and confirmation.

The Metropolitan Life Insurance Company has likened diabetes to "a lion caged." "A diabetic must be reminded," it says, "that if he lets the lion get out of control, he runs a risk which may be fatal." With the help of insulin, what was previously a wearing and spirit-breaking existence is now one of promise and assurance. "He should be warned, however, that with the use of insulin, he is not cured, and that grave danger still remains."

Can dentistry help to keep the lion caged? Are oral conditions and diabetes in any way inter-related? It is my purpose to turn the spotlight upon these possibilities, and examine them more closely.

The fact that disease most often attacks the body by gaining entrance through the mouth has led to the dictum, "Shut your mouth and save your life!" George Catlin, a London lawyer and a keen observer of human habits,

said fifty years ago "There is no animal in nature, excepting man, that sleeps with its mouth open. If, like other animals, he used his nostrils to warm and purify the air in its passage to the lungs, respiratory infections would be nil." The more recent statement of Dr. Percy R. Howe of the Forsyth Dental Infirmary for Children in Boston, "Open your mouth and behold an index to the health o your whole body," is now regarded as an in disputable truth; for the mouth and the body are extraordinarily interdependent in health and disease.

In surveying the common field, we can find the two extremes: first, the fanatics who believe that "all ills are either mental or dental"; and, second, fanatics who refuse credence to the focal infection theory, and who deny that oral disease may be closely linked with general disease. If, however, we add these two groups together and divide by two, we might arrive at the following summary:

1. Improper assimilation of food affects the tissues of all parts of the body.

2. Lowcred resistance, attributable to the above condition, invites infection, especially in the oral tissues.

3. Oral infection must influence other parts of the body.

 Any infection makes diabetes worse—an axiomatie assertion.

5. Loss of tooth structure and impairment of masticatory function must likewise affect other parts of the body.
6. The diabetic is dependent upon a re-

stricted diet.

7. A good masticatory apparatus is necessary to the diabetic.

8. A healthy mouth and the diabetic's chances to keep the lion caged are interdependent.

If we accept, as a working hypothesis, that oral conditions and diabetes may be interrelated, let us proceed to examine the oral conditions which are most commonly found in the diabetic patient; let us see if we can detect any association between oral diseases and diabetes; and let us consider measures for the treatment of oral disease and their relation to general efforts to keep the lion caged.

For purposes of study and presentation, I have divided all diabetics into three age

groups, as follows:

Group 1: Cases under twenty years of age. Group 2: Cases from twenty to fifty years of age.

Group 3: Cases over fifty years of age.

These divisions correspond to those used in analyzing groups of non-diabetics, who, so far as can be determined, never have restricted their food intake. In all cases the diabetics studied statistically had had the disease from one to twenty-five years before the oral examination.

In the series of cases designated as Group 1, we found that a child who has been on a rigid diabetic diet during the tooth developing years is usually free from dental caries. This observation is not startling because such a diet is notably similar to the diets suggested by the scientific workers interested solely in the control of the prevention of decay. Despite this relative freedom from decay, however, there is a marked tendency toward tartar deposit—and this is true of all our age groups. Children of no more than eight or ten years of age who have had diabetes for over a year will invariably exhibit inorganic salt deposits about the lingual surfaces of the lower incisors and the buccal surfaces of the maxillary molars. In such a child the calculus seems to be entirely of salivary origin rather than derived from the blood, although, as we shall mention later, we found an abundance of both salivary and serumnal deposits in the other two groups.

In diabetes, the precipitating processes appear to occur readily in the calcium-containing body fluids. An abnormal deposition of calcium appears in the arteries as arteriosclerosis; in the gall bladder and kidneys as stones; and sometimes in the skin and veins as calculi. In untreated diabetes, there is a noticeable loss of calcium and phosphorus from the bones of the body by way of the urine and feces. It is not unreasonable, then, that a marked precipitation of salts should be noticed in the mouth of serumnal as well as salivary genesis. The prevalence among diabetics of mouths which are handicapped by heavy tartar deposits is a striking observation.

I am of the opinion that without a physician's insistence upon adequate mouth health, and without the health education so essential to diabetic treatment, larger numbers of these Group 1 cases would be obliged to wear full dentures before they reached the age of twenty years. Fortunately, because of the dangers to diabetes from infection, the physician in charge demands that mouth health be maintained, and the patient is made to thoroughly appreciate its importance. Regular appointments and adequate dental supervision ensue, and an opportunity for actual prevention is at once established.

The soft-tissue picture in the patients of the first group is not unlike that of any healthy child: the gums are pink and free from peridental lesions, provided, of course, that inpinging tartar deposits are not allowed to remain. Here, dental care and treatment are largely confined to hygienic measures, perhaps more energetically pursued than in the average non-The cooperation of the diabetic patient. parents, as well as the child, is enlisted, and careful prophylaxis should be performed at least every three months. The regulation of malposed teeth, the development of the arches, and the correction of malocclusion are also preventive measures whereby oral health can be maintained. If, perchance, carious teeth are disclosed, they should be promptly treated and all non-vital teeth should be removed.

Group 2, encompassing diabetics between twenty and fifty years of age, presents a different problem from Group 1. Diet, heredity, and individual hygienic habits have largely determined the condition of their mouths, so that it is difficult to disclose how far the condition of diabetes has complicated the mouth picture. If their diet has been restricted from early youth, their oral health may be good. If, however, their diet has been unbalanced in favor of carbohydrates and against fresh fruits and vegetables, a more likely situation, they will exhibit many carious teeth; a marked absorption of the alveolus, generally more advanced than in the non-diabetic of the same age; and a number of peridental pockets, some of which may be exuding pus.

Tartar of serumnal origin is more prevalent than in the cases of Group 1. Peridental lesions respond less easily to treatment than in the case of the average non-diabetic. Here, as with all diabetics, we should never be forgetful of the axiom that any infection makes diabetes worse, and be prepared to advise accordingly. Following the initiation of general diabetic care, there should be a noticeable abatement of dental caries in the young adult, although a continuance of tartar deposits and

peridental damage. These eases demand more immediate and careful treatment than those of Group 1. Peridental lesions should be accurately charted and treated according to their severity. No discharging pocket should be allowed to persist.

This second group is the one which is likely to develop cardiac insufficiences, kidney disabilities, and other organic changes if we, who who are charged with treatment, do not appreciate the potential danger of neglected foci of infection. It is not unlikely that we may lessen arterial degeneration by maintaining a healthy mouth in the diabetic patient by eliminating oral foci; and, under such conditions, we can sometimes permit liberties in the living regime that would otherwise be tabooed.

Group 3, or diabetics of fifty years or over, is comprised largely of patients who are wearing full dentures. Several interesting hypotheses were suggested from a study of this group. Noticing that most of these patients were toothless, we found, on further inquiry, that a majority of them had lost their teeth before they became diabetic. They invariably said that their teeth were so loosened from pyorrhea that they were forced to have them removed years before. I believe that we can safely assert that these teeth were lost because of some disease condition probably attributable to a serious metabolic disturbance. Hence, we wonder whether both the diabetes and the peridental lesions were not the common consequence of the same metabolic deficiency. The fact that their mouths were bad enough to warrant complete extraction before the diabetic onset, made it reasonable to suppose, also, that the earlier condition of extensive oral disease might have been an indicator or warning of the diabetic condition to come. Might not, then, the carlier care of these extensive oral lesions have acted to delay or even prevent the incidence of diabetes, in so far as the metholic disturbance was thereby revealed? This is a question worthy of deeper study.

Of the total number of diabetics examined in 1932, fifty per cent could be classified as giving their months poor home care; twenty-five per cent pay fair attention to this matter, while only the remaining twenty-five per cent could be regarded as giving anything like adequate home care to their teeth and soft tissues. Among these twenty-five per cent who properly care for their teeth at home, and who make and keep regular dental appointments, there are a few, who, though over sixty—and diabetic for a number of years—have been able

to avoid becoming toothless without jeopardizing their health. Lower dentures are more effectively managed if a few healthy, well-located teeth are present. To preserve even a few is often possible; to save many, not an improbability. I have had one patient of sixty-eight years of age who has had diabetes for three years and possesses twenty-eight teeth. Many of these teeth are heavily filled to be sure, but there are no foci present as she has taken excellent care of her mouth. These facts are another indication that on the whole good dental care is a necessary part of every one's life.

It ought to be fairly obvious that the physician should insist upon adequate dental attention for his diabetic patient. The dentist should appreciate the diabetic's increased susceptibility to peridental disease and make every effort to control it. The patient should cooperate with both physician and dentist. These are the prerequisites for the retention of healthy teeth in the diabetic patient.

The physician is usually the first to see the patient ailing from diabetes. Unless that patient is forcibly impressed with the importance of a healthy mouth, he or she will undoubtedly be wearing full dentures before long. Of all the edentulous diabetic patients we examined in 1932, we found that sixty-six per cent were either infrequent visitors to the dentist, or had no care at all. Dental care is imperative, otherwise focal infection, with its attendant general dangers, will freely attack the mouth.

Can dentistry be of service to diabetics? The answer to that question is patent. But the other question—is there a prediabetic stage, discernible by oral changes which, if discovered early, might delay or even prevent the onset of diabetes—must remain as yet unanswered.

The marked susceptibility to oral changes before and during the disease, together with the number of diabetics who are endentulous before the onset, I feel to be more than a mere coincidence. Dentistry hopes to extend its service to all the people. Sugar tolerance tests and various other metabolic determinations, when applied to patients with progressive or persistent peridental pathology, may produce valuable data. Such a study should contribute information which may help in the control of diabetes; but from a broader point of view it will provide a new and interesting connecting link between dentistry and medicine, whose aims are, after all, the same-maintenance of health and prevention of disease.

NUTRITIONAL CONTROL OF DENTAL CARIES

By EWING C. McBEATH, M.D., D.D.S., NEW YORK, N. Y.

Part of a Symposium on Dental Conditions as They Affect General Health, presented at the Annual Meeting of the Medical Society of the State of New York, at New York, on April 4, 1933.

ROBABLY the commonest of diseases which afflict civilized man is dental caries; its ravages are more widespread in each succeeding generation. Statistics show that today probably 95 per cent of school children suffer in varying degrees from tooth decay. It has been recognized of late, moreover, that dental caries, while a disease in itself, is also very often a symptom of serious or potentially serious systemic conditions. The continual increase in its prevalence constitutes a menace that grows more threatening, almost from year to year. The ultimate aim in the study of this disease is, of course, to discover a means for its prevention as well as for its control. It is an involved problem, going much deeper than local manifestations. A systematic and comprehensive study of the problem was made possible at the School of Dental and Oral Surgery, Columbia University, in February, 1930, through the generous aid of the Commonwealth Fund. The special Caries Research Advisory Committee and the special Caries Research Staff of the School divided the problem into five phases: biochemical, bacteriological, histological and pathological, animal experimentation, and clinical experimentation. This is a presentation of the phase of human nutrional work from February, 1930, to June, 1932.

Much work had formerly been done by others, and a great deal written on researches in this field. In order to discover what was authoritative and pertinent, much of the literature on this phase was reviewed before experimentation was begun. It was evident that metabolism plays a prominent and effective role in establishing increased or decreased resistance to dental caries. None of the dietary studies to date, however, clearly indicate whether the influence of diet is on the environmental factors or on the ability of the tooth structure to resist the attack of the environmental factors. Each view has its advocates; it is possible that the sum of the dietary factors may function in both the ways cited above.

It seemed desirable, then, first to observe the effect of a well balanced so-called "protective" diet on the teeth of children in which caries was already present. If such observations indicated a nutritional control in operation, the next step, obviously, would be to analyze and evaluate its makeup. The results obtained by Doctors C. L. Drain and J. D. Boyd of the University of Iowa in groups of hospitalized children under dietetic manage-

ment lead us to select the so-called "protective" diet suggested by them for our preliminary observation. They found that carious dental tissue became very hard and there was no further spread of dental caries. We finally selected three institutions just outside of New York City which are conducted on the cottage plan. Under this system it was possible for us to segregate children for dietetic management. These homes are designated as A, B, and C. In each of these we had an experimental group of about 30 children and a control group averaging about 20 children, the ages ranging from 9 to 14 years, boys and girls.

At Homes A, B, and C the general dietary experiments were conducted. The work involved the feeding of children in three homes over a perod of from six to seven months, during which time the experimental diet was contrasted with group feeding of control groups on the unsupplemented basal diet of these homes. These basal diets were of themselves of a high standard, built on recognized principles of nutrition, hence the contrast between the experimental groups and the control groups is of a lower degree of difference than might otherwise have developed. The experimental diets insured the following ration of protective foods per day:

- 1 quart of milk
- 1 or 2 eggs
- 1 serving of meat, fish, chicken or liver
- 2 vegetables (½ cup considered as a medium serving)
- 1 orange or apple or tomato
- 1 fruit besides the above
- 6 teaspoons of butter
- 3 teaspoonfuls of cod-liver oil

In addition to the general dietary experiments we also conducted an experiment to determine, if possible, the specific relation of vitamin C to the control of dental caries. This experiment was conducted at a state institution for children designated as Home L. One hundred fifty-two children were selected, eighty-eight in the control group and sixty-four in four experimental groups of sixteen each. This experiment was conducted, uninterrupted, for nine months. The large control group was kept on the unsupplemented regulation diet of the home, which was of a fairly high standard. The experimental groups were also kept on the regulation diet of the home,

the supplemental feeding of the best sources of vitamin C as follows:

Group II—Juice of 3 oranges and 3 ripe bananas daily
Group III—8 oz. orange juice daily
Group IV—6 oz. tomato juice daily

The dental examinations in all homes were as thorough as possible. Any abnormal condition of the gums no matter how slight, was recorded as to its degree of severity. teeth were carefully examined as to the character and color of the enamel, stains, cleanliness, abnormal conditions, and caries. cavities were noted and recorded on special charts. Any fissure deep enough to catch the explorer was reported as a cavity; these were carefully noted. The compound cavities were also outlined on the charts according to their location and involvement of tooth structure. The precentage of carious dental surfaces was determined by calculating the number of tooth surfaces in each case, five surfaces for each tooth. The carious dental surfaces were then counted and the percentage of the total number of surfaces presented computed. It is shown from our findings that at the conclusion of the studies there was, consistently, in Homes A, B, and C less caries in the experimental groups. In two of the homes the final examinations showed dental caries to be 61/2 times more prevalent in the control groups than in the experimental groups. In the other home the control group showed dental caries to be 11/4 times more prevalent than in the experimental group.

In Home L, where the vitamin C experiments were conducted, it is doubtful that the differences were significant, either as to dental caries incidence or changes in gum conditions.

In order to more accurately evaluate the results obtained during the year 1930-31, we decided to repeat our dietary experiments in the same homes during 1931-32, using the same groups for our observations, and reversing them; that is, making the controls of the previous year the experimentals, and the experimentals of the previous year controls. The diets used, the sizes and personnel of the experimental and control groups, and the time involved were approximately the same as during the previous year.

In addition to the general dictary studies, an attempt to observe closely the effects of the administration of the best sources of vitamin D in the control of dental caries was undertaken at Home X. an institution just outside of New York City for the reclamation of boys and girls, private and public charges. The experiment consisted of the addition of these sources to the regulation diet

of the institution. No changes whatever were made in the daily routine of any of these chil-Three groups of boys were selected, carefully paralleled as to age and caries incidence, the age range being from ten to fourteen years. The control group numbered 23 and the experimental groups numbered 21 and 19, respectively. The usual dental examination was made of these groups in December, 1931. Arrangements were then made to administer to one group consisting of 21 boys, 15 drops of Viosterol to each child per day. The other experimental group, consisting of 19 boys, was given light radiation twice per week from a Burdick quartz mercury solarium lamp installed in the hospital for this purpose. Experiments were begun in January, 1932. There was no interruption whatever in the administration of Viosterol to one experimental group and the light radiation to the other group. The final dental examinations at this institution were made the latter part of May, 1932. An analysis of the representative menus selected at random from the files of Home X showed the diet at this home to be a close approach to accepted standard diets for children in the age range of nine to fourteen years. The children were all well, or fairly well nourished, no cases of poor nutrition being found in any of these groups.

The findings after the final dental examination in May, 1932, were very similar to those of the 1930-31 experiment. In two of the homes at which we conducted the general dietary experiments, Homes B and C, the control groups again showed dental caries to be about 6½ times more prevalent in the control groups than in the experimental groups. The findings at Home A, however, after the final examinations, showed that the experimental group did not have any new dental caries from the time of the first dental examination in December, 1931, until May, 1932. The control group in this home showed a percentage increase of 1.6 per cent, 1½ new cavities per child.

The findings in Home X, in which we conducted the vitamin D experiments, were extremely interesting. After the final dental examination in May, 1932, our data showed a difference in the caries index of the control group and the group receiving 15 drops of Viosterol per day of 1.7 and 28, approximately 1 to 1.6. However, the irradiated group showed an increased resistance to dental caries, namely, .32 per cent increase as compared with 2.8 per cent increase in the control group, approximately 1 to 9. In other words, the Viosterol group showed 5½ times more new cavities than the irradiated group at the final dental examination. The increase of dental

caries in the irradiated group at Home X was slightly less than the increase in the general dietary experimental groups at Homes A, B, and C. The protection afforded by the quartz mercury lamp radiation is apparently as good or better than that afforded by the protective diet.

An outstanding effect of the experimental diets in our series was to increase the bulk of food eaten, with only a slight decrease in calorie intake and a very slight increase in actual grams of carbohydrate consumed. In spite of the fact that carbohydrate intake was actually increased, it did reduce the cane sugar and cereal forms and increased the fruit and vegetable forms. In so doing it may have affected the oral bacterial flora. Our observations did not measure such bacterial changes.

In none of these groups was there inadequacy of calcium intake. Since we have no retention data on these cases, it is impossible to say whether utilization was better in one group or the other. In spite of this lack of data on utilization, there are two features of the diet which suggest a possible difference here. Increase in fruit juice aids in the absorption of calcium. Decrease in fat also lessens the danger of the elimination of unabsorbed calcium soaps in the feces. The fact that experimental group at Home C, however, actually increased its fat intake over the conexprimental group A, tends to reduce faith that variation in fat intake was significant trol and yet had the same caries reduction as here.

It is, of course, obvious that the increased amounts of milk, egg, cod-liver oil, fruits, and vegetables would be expected to produce very marked differences in vitamin values. A, B, C, and D vitamins were all much increased in this series of experimental groups.

If one sought confirmation of Mellanby's views as to the importance of vitamin D, our series would tend to support this view. It was the vitamin most tremendously increased by the diet. The increase in A is next greatest and in B and C next in order.

The studies at Home L were devised to

evaluate the effect of added vitamin C in three forms, orange juice, tomato juice, and bananas. From the data one cannot draw support for the view that vitamin C was of prime importance in the differences observed.

Variations in caries in the groups fail to show vitamin B as the significant single responsible agent. The vitamin B work does suggest, however, that total caries incidence may be correlated to a degree with total vitamin B intake. We get less incidence with dosages of over 400 units than under this amount; and when these vitamin B figures are compared with those obtained in another connection to establish the human requirement, it appears that 400 or better are needed for full normality of human gastro-intestinal function.

Our findings in the Home X experiment corroborates our claims of the previous year regarding the importance of vitamin D in the control of dental caries. More concentrated work will be done to determine the relative effects-from the administration of vitamin D from its best known sources.

Conclusions

1. They tend to confirm the theory of the importance of diet as a factor in the nutritional control of dental caries.

2. They supply a set of differences corre-

lated with reduction in caries.

- 3. The regulation diets were most deficient in the foods known as the best sources of vitamin D. These were most increased in the experimental diets.
- 4. There is a striking difference in the effects of the administration of the different sources of vitamin D, the quartz mercury lamp radiation apparently affording much greater protection than Viosterol, in fact, quartz mercury lamp radiation would seem to be as effective as a protective diet in the nutritional control of dental caries. Further study of the effects of quartz mercury lamp radiation will probably disclose many factors involved and make possible its proper evaluation for comparison as a vitamin D source.

PYORRHEA ALVEOLARIS:—ITS RELATION TO ORAL AND GENERAL HEALTH

By ARTHUR H. MERRITT, D.D.S., NEW YORK, N. Y.

Part of a Symposium on Dental Conditions as They Affect General Health, presented at the Annual Meeting of the Medical Society of the State of New York, at New York, on April 4, 1933.

PYORRHEA alveolaris is a chronic disease affecting the supporting tissues of the teeth, the chief characteristic of which is suppuration and a progressive destruction of the alveolar process. This destruction does not occur uniformly throughout the mouth nor around the individual teeth; it may be quite

extensive about certain teeth, while others in the same mouth, remain unaffected.

Coincident with this bone loss, pockets are formed about the teeth the depth of which will depend upon the extent of alveolar destruction. These pockets are bounded on the one hand by the gums which remain at approximately their normal level at the cementoenamel junction, and on the other, by that portion of the root surface from around which the alveolar process has been destroyed an examination be made of these pockets, it will be found that the inner wall of the gum tissue presents a more or less raw and granulating surface, while the root, forming the other wall of the pocket, is covered with the remnants of the necrotic pericementum plus a It has been considerable calculary deposit said that a ease of pyorrhea in which the pockets average one quarter meh in depth, presents seven and one-half inches of ulcerating surface from which bacteria may be absorbed 1 Pollowing the formation of these pockets infection and suppuration occurs. The organisms engaged in the infective process are principally the fusiform bacilli, vibrois, spirochetes, and cocci acting in symbosis They are all normal inhabitants of the mouth but under conditions of disease their numbers are enormously mereased Tirst place among these the organisms is usually given to group,3 though this is questioned by Smith2 who expresses the belief that cocci alone cannot invade and destroy the periodoutal tissues He gives preemmence to the fusospirochetal organisms which he says produce powerful necrotizing enzymes and prepare the way for the symbiotic action of the different groups, none, however, can be regarded as in any sense specific

Pyorrhea is chiefly a disease of adult life and has as its principal cause two factors First, some disturbances in metabolism apparently connected with avitaminosis and affecting the acid base balance of the hody, in such a way that the basic elements are increased, and secondly, invasion of the periodontal tissue by bactern. The first may The first may be regarded as the predisposing and the second as the local active cause though there are also local predisposing factors which explains why it is that some teeth become serlously involved while others in the same mouth remain unaffected In any study of pyorrhea, these two major factors in etiology need to be clearly understood if one is to correctly appraise its local and systemic effect

LOCAL EFFECT

The local effect of pyorrhea is the establishment of a chronic infection which unless interfered with by treatment, may continue throughout most of adult life or until the entire alveolar process is destroyed and the teeth exfoliated. In the study of six hundred individual cases. Blick, reports hiving found pyorrhea to be present in 13% of those be tween the ages of twenty and twenty-four and

mereasing up to 88% in patients over fifty. Because it is usually not painful and in its carly stage gives little evidence of its presence, it is generally overlooked by patient, dentist and physician The result is that in adult life it is one of the most common of chronic infec-To further complicate the situation, there is an impression abroad that it is an incurable disease, about which little ean be done. The end result is an obscure infection which slowly destroys the alveolar process, the finale of which is the complete loss of the While it is true that there are still unsolved problems in its etiology, failure in treatment is not so much due to this fact as it is to neglect to make use of the knowledge already at hand, the application of which would make the prevention and treatment of pyorrhea one of the most satisfactory procedures of dental practice, for it can be said without fear of contradiction, that pyorrhea is a eurable disease needing only expert care to affect a permanent cure, though like many other diseases it may reach an incurable stage

Prognosis depends upon the extent of alveolar destruction the number of teeth remaining and No attempt at the nature of the occlusion diagnosis and no expression regarding prognosis, should be made until a careful study of all three has been made. To attempt to do this from roentgenograms alone as is sometimes done, cannot be too strongly condemned, for they reveal only a part of the evidence upon which both diagnosis and prognosis depend Loss of alveolar process as shown by the roentgenogram is not necessarily pyorrhea A thoroughgoing clinical examination, plus experience in its treatment, are essential in making a correct diagno-

sis and in outlining treatment

INFLUENCE ON GENERAL HEALTH

One of the puzzling questions concerning pyorrhea and one of the most important is, What, actually, is its relation to general health?

We have seen that it represents a chronic localized infection which may continue for many years; that the pockets about the teeth are always filled with a teeming mass of mixed bacteria, and that in adult life it is one of the most common of all foci of infection What, then, is its status as a possible cause of secondary infection?

Many answers have been given to this question, varying all the way from complete indifferences to accomplete indifferences indifferences to accomplete indifferences to accomplete indifferences indifferences to accomplete indifferences indif

ferences to over exaggeration

With a view to ascertaining the truth, a group of research workers at the Mayo clinic undertook a series of experiments to determine as far as possible, just what its status as a cause of secondary infectious might be?

They found that when rabbits were inoculated with streptococci obtained from patients having pyorrhea, plus some secondary infection suspected of being caused by the focus in the mouth, these same secondary infections were reproduced in certain instances in the experimental animals. In arthritic cases for example, they were found to be as high as 30%; in lesions of the colon resembling colitis, 25%; in cases of ulcers of the stomach and duodenum, 42%; in iritis, 37%, and in cholecystitis, 25%. These results have been confirmed by Rosenows, who states that primary cultures taken from pyorrhea pockets have a wider range of localization than do those of periapical infections—a fact contrary to general belief.

The conclusions reached by this group are that "we are as much justified in considering purulent and septic conditions around the teeth as sources of disturbed states of health as we are purulent processes found in the urethra and tonsils." This opinion is held by others, notably by Black⁵, Hartzell¹, Haden⁹, and Cook¹⁰. My own experience in the treatment of pyorrhea abundantly confirms these observations, for in many instances there is a noticeable improvement in general health following treatment of which the patient is conscious.

The symptoms produced by pyorrhea will depend somewhat upon the portal by which the organisms gain entrance to the body. These are three in number: First and most common, through the gastro-intestinal tract, which explains the frequency of gastric and

duodenal ulcers reported in these cases. Secondly, direct infection of the blood stream by organisms from the pyorrhea pockets, also a common portal of entry, and thirdly, through continuity of tissue by which the sinuses and respiratory tract may become the seat of secondary infections. "Whatever may be the exact mechanism of infection," says Sir Kenneth Goadby11, "or what actually determines the production of symptoms, there is overwhelming evidence that diseases of many varieties, or better, disease symptoms of many kinds are directly referable to the unhealthy state of the oral mucus membrane. Oral focal infection is one of the best fields for the investigator in the elucidation of the problem of gradual lowered resistance and the induction of remote disease through bacterial invasion. It is true that the correlation of the microorganisms in the infected focus with the remote symptoms is not always easy, and frequently highly unsatisfactory from a strictly laboratory view; at the same time, the gradual deterioration in the function of organs continually subjected to mild but frequent doses of poisonous substances must finally materially effect the general body metabolism." The answer then to our question is that all evidence, clinical as well as laboratory, points to the fact that pyorrhea as a cause of metastatic infection should be given serious attention by both dentist and physician and that it is only through their cooperation that the problem can ever be satisfactorily solved.

ORAL CONDITIONS AS AIDS IN DIAGNOSIS OF SYSTEMIC DISEASES By LESTER R. CAHN, D.D.S., NEW YORK, N. Y.

Part of a Symposium on Dental Conditions as They Affect General Health, presented at the Annual Meeting of the Medical Society of the State of New York, at New York, on April 4, 1933.

E can divide patients into two classes. Those that are driven to the dentist because of subjective symptoms and those that come conscientiously for routine examination.

The subjective symptoms are: pain, blccd-

ing and consciousness of a growth or swelling.

Pain may be due to:

- 1. Ordinary toothache.
- 2. Reflex odontolgia from sinus disease.
- 3. Burning and sore tongue and mouth.

- 4 Gingivitis and stomatitis
- 5 Painful loose tooth or teeth

Bleeding from the gum and oral mineous membrane may be caused by

- 1 Local inflammatory conditions
- 2 Blood dyserastis
- 3 Avitaminosis or cudocrine disturbance Swelling or growth may be due to
 - 1 Tumor or cyst
 - 2 Osteitis fibrosa cystica
 - 3 Pagets' disease of bone
 - 4 Atypical guiuna 5 Tubereuloma

Objective symptoms are those discovered by the patient in self examination or during routine 1-ray and clinical examination. These are

- 1 Dental caries
- 2 Paradentosis (Pyorrhea)
- 3 Secondary syphilides
- 4 Lichen planns
- 5 Leukokeratosis
- 6 Geographic tongue
- 7 Pigmentation
- 8 Foul breath

Subjective Symptoms

Pain In this discussion we can immediately dismiss evident odontalgia. If it is of local origin it is easily discovered and relieved If it is caused reflexly from sinus disease there is little difficulty in determining this fact.

The sore burning tongue and mouth are not infrequent problems confronting the dentist. Many times the pain and discomfort far exceeds any visible lesion. This condition is seen in Addison's Anemia and may be present for some time before any blood changes can be demonstrated. If, coupled with this mouth soreness, there are digestive disorders and numbness of the finger-tips, permierous anemia should be strongly sus-ected A clean, polished looking tongue with atrophic pipillae is also suggestive of primary anemia.

Sprue manifests itself in a sore tongue and digestive disturbances but as a rule there is free hydrochloric and in the gastric junce and less atrophy of the lingual papille. The blood changes also differ from those found in permicous menna.

Herpetic inlers (conker sores) are frequently observed by dentists. They have a complex origin and present difficulties in diagnosis. They are most frequently associated with digestive disorders but are also seen in pernicious anemia. Avitanimosis plays a part in their formation. In severe cases oral pempligus must be considered.

Acute gingivitis is a common oral condition I should say that practically all cases of acute

gingivitis are of bacterial origin. What may be the underlying cause that has so lowered the resistance of the gingival tissue that infection can take place, is a different story.

Of late years we have heard a lot about "Vincent's Gingivitis". The term has been used "ad maneam" and it is about time it was discarded. The finding of the fusic-spirillary combination means nothing, they can be found in practically every inflammatory area in the gim. For that matter, they can be demonstrated in normal gim. They increase in number, however, as the parts become inflamed.

I am happy to see that recently careful observers are calling attention to the folly of making suicars from gingival and oral lesions and basing diagnoses on them. Lichtenberg, Werner and Lueck state after clinical and experimental study on this problem that, "The value of diagnostic sinears for Vincent's organisms as a means of establishing a pathogenic relationship of these organisms to a suspected lesion is questioned." Becks recently wrote "On the basis of present knowledge the sinear test does not afford any information concerning the etiology, the diagnosis, the therapy or the prognosis of the disease."

Acute guignitis especially where there is a gaugrenous or illectous picture, is a frequent accompaniment of many serious systemic conditions. Permicious anemia, the linekemias and agrantifocytosis exhibit an ulcerous ginguitis during some phase of the disease. This is especially true of the last two conditions.

Diabetes, avitaminosis, drug absorption, pregnanes and endocrine disturbances also predispose the gum to secondary infection. It should be borne in mind that the gingivitis accompanying any one of these conditions is usually dependent in its severity on the amount of oral sepsis or lack of hygiene present.

An acute gingivitis demands, at all times, a thorough examination to find whether a contributing cause exists This examination should include besides a thorough questioning as to diet, etc., a red, white and differential blood count and a urine analysis Sometimes a Wassermann test is indicated Where no serious contributing cause can be found we feel that we are dealing with a simple local infection and these are readily amenable to treatment If systemic complication is discovered consultation is imperative. Where the gingivitis is secondary to a general disease, such as any of the blood dyscrasias, all that can be done in the mouth is to keep it in as antiseptic a condition as possible

It is at times most astonishing to watch the

cessation of the gingival lesions when the systemic condition is righted. I have seen this occur where liver therapy was given in anemia, or the diet corrected in avitaminosis and in one instance small doses of thyroid extract proved most efficient.

We come now to a not uncommon cause of discomfort, the loose and painful tooth. On the surface this is an apparently easy condition to diagnose. The vast majority of loose painful teeth is due to acute paradentosis, but there are some cases in which such a simple cause is not responsible. I know of two instances where the first symptom of acute lymphatic leukemia was a loose painful tooth. These teeth, strangely enough, were in the mouths of dentists and both cases ended fatally.

Neoplastic invasion may loosen teeth and is sometimes the first signal to warn the patient that something is amiss.

Bleeding from the Gum and Oral Mucosa.—Bleeding from the gum often sends the patient for advice and relief. The greatest cause of bleeding gum is a simple gingivitis due to tartar and lack of oral hygiene.

Gingival bleeding is seen occasionally during menstruation and in pregnancy, especially in

the early months.

The type of bleeding that occurs in the above conditions is not constant and is usually noticed during some such trauma as tooth-brushing. The advertisement of "pink tooth-brush" has made people conscious of a condition that otherwise would have been ignored.

There is, however, a sudden steady oozing from the gum and oral mucous membrane that is alarming and has a serious underlying cause. This bleeding may or may not be accompanied by oozing from the nose and petechial hæmorrhages in the skin. This condition is met with inidiopathic purpura, primary and secondary anemia, acute leucemia and in severe avitaminosis. Blood examination will aid us in making a diagnosis. It must however be remembered that in the early stages of acute myeloid and lymphoid leucemia the white blood count may be within normal limits or show a moderate leucocytosis, and since these conditions, in their incipiency, suggest an acute infection the blood count may be misleading. search should be made of the stained blood smear for myeloblasts and lymphoblasts and a daily white count is necessary.

Idiopathic purpura usually has a greatly diminished platelet count. The tourniquet clotting time, and clot retraction tests are also

useful in this disease.

Consciousness of a Growth or Swelling.—Patients come to the dentist because they feel a swelling or lump, or some one has noticed a change in the contour of their face. A local-

ized exogenous tumor may present little diagnostic difficulty but in all cases histological examination of the removed growth is demanded. Lymphoid leucemia at times may result in leucotic deposits in the gums, giving rise to either a circumscribed growth or to a hypertrophic gingivitis. The histology in an instance of this kind will give some clue to the true condition, since the oral lesion may precede for some time any definite blood change. Similarly the giant-cell tumor, so insignificantly considered, may be the osteoclastoma of generalized osteitis fibrosa. Recent discussions on this disease have brought out the interesting fact that the first symptom in several cases had been a tumor of the jaws wrongly diagnosed as a giant cell epulis.

A central lesion in the bone expanding the plates calls for a fair amount of diagnostic acumen. We may be dealing with a simple cyst of the dental system. This condition is usually associated with either a pulpless tooth, or a region where a tooth had been previously extracted, or with an unerupted tooth.

When, however, an x-ray examination reveals a cyst not associated with a tooth, further investigation is called for. We must determine whether we are dealing with some such neoplasm as an adamantinoma, giant cell tumor, myeloma or an oral expression of osteitis fibrosa cystica or of the rarer conditions of Gaucher's Disease or Niemann's Disease.

Good x-rays of the lesion must be had. A biopsy and aspiration may help, also a complete blood and urine chemistry and in some instances x-ray examination of the entire skeleton are indicated.

In my experience I have seen two swellings in the mouth that proved to be atypical gummas. In one case the swelling resembled a sub-acute alveolar abscess, in the other a common gum-boil. Both these lesions disappeared on anti-luetic treatment after routine surgical procedures based on faulty diagnosis had failed.

I have encountered tuberculosis in the oral cavity either as an indurated ulcer or a tuberculoma and the lesions followed tooth extraction. The diagnosis was made upon the histological examination.

We now come to a number of conditions that usually give no subjective symptoms and are discovered during routine clinical and x-ray examinations.

The commonest lesions thus discovered are dental caries and paradentosis (pyorrhea). Both of these conditions have a systemic origin, the discovery of which is taxing the ingenuity of physicians, dentists and research workers the world over. When I say caries and paradentosis, I do not mean the occasional

decayed or loose tooth in an isolated field; I mean caries prevalent thoughout the mouth or diffuse alveolar dystrophy. Both these diseases are closely bound up in the problem of calcium and phosphorous metabolism, and just what is causing the imbalance is at all times difficult to find out. Dietary, metabolic and endocrine dysfunction are either singularly or in combination involved.

Soft tissue lesions are also discovered during routine examination. While the syphilides are not so commonly seen in daily practise all nucous patches and excoriations of the mucous membrane should be considered suspiciously at least as a safeguard to the operator.

Lichen planus is not uncommon and may be present in the mouth without associated skin lesions. Leukokeratosis is also frequently

seen.

The geographic tongue is a source of worry to patients and even to dentists. Its cause is unknown but I have observed its most pronounced appearance during a digestive unset.

Fortunately foul breath is not of daily occurrence in practise, but when it does occur its cause must be ascertained as quickly as possible. Oral filth, digestive disorders, nasal and sinus disease are the commonest responsible factors. There is also a condition that has been termed "ozena of the tongue" that causes a most fetid breath. It is believed that a mycotic organism attacking the dorsum of the tongue is the cause. If the tongue is scraped the debris thus removed has the characteristic odor of the breath.

Pigmentation of the gum and oral mucous membrane is not unusual. I have noticed several types of pigmentary change. There is the one that is circumscribed and confined to one spot on the gum, it resembles the color of blue tatoo and is due to a silver amalgam filing impinging on the gum or to a piece of amalgam becoming dislodged during an extraction and embedded in the tissue. Sometimes an x-ray will disclose the presence of a small piece of the metal.

Of course the pigmentary changes due to lead and bismuth are well known. We see little lead symptoms but with the advent of bismuth in the treatment of lues, the bismuth

line is occasionally seen.

Brown melanotic pigmentation is common in the mouth. It is characteristic in the negro,

Hindu, some Latins and Hebrews.

Dr. Laidlaw and I have shown that melanoblasts are present in varying numbers in all
gum. When they are activated melanin is made
and for this reason we occassionally find this
type of pigmentation in the field of a chronic
gingivitis. Diffuse brown discoloration of the
oral mucosa, coupled with bronzing of the
skin is seen in Addison's Disease.

Before closing I should like to briefly mention the atypical symptom of numbness. I have seen two striking examples of this complaint and in each ease the result was different. In the first instance the numbness was in the region of the distribution of the infra orbital nerve. This was the precursor of multiple sclerosis. In the second case the patient complained of numbness in the chin and anterior teeth. This girl turned out to be a schizophrenie.

In the foregoing I hope I have been able to demonstrate to some degree the close relationship between mouth symptoms to disease.

CONGENITAL ATRESIA OF THE ESOPHAGUS

By L. T. PERRAULT, M.D., AND H. J. BURMAN, M.D., NEW YORK, N. Y.

From the nose and throat service of St. Luke's Hospital, New York City.

CONGENITAL atresia of the Esophagus presents one of the problems which medical science and ingenuity has as yet been unable to solve. The condition is by no means rare, but is so distressing to the patients and physician that ever since Durston in 1670 recorded the first recognized case, it has been considered worth while publishing one's experience with this anomaly.

Congenital atresia is due to a developmental error and must arise at a very early stage; because in the 4 mm. embryo the trachea is already separate from the Esophagus. To explain the most common type of atresia in which a tracheo-Esophageal fistula also occurs, many theories have been advanced, the one most

widely accepted being that of Shattock. To put it simply, the posterior wall of the intestinal tube is forced over to the posterior wall of the respiratory tube, forming a fistulous opening, becoming adherent, and forming a closed pouch in the intestinal tube superior to the adherent surface. The tracheal opening varies in size, the edges are always smooth, and the mucus membrane of the two tubes uninterrupted. The muscle walls of the two passages are frequently blended without any line of demarcation. Occasionaly rudimentary tracheal cartilage is found in the tracheal portion.

Atresia of the Esophagus is often associated with other developmental defects such as hare-

lip, cleft palate, and atresia ani. In atresia the upper portion of the esophagus usually ends in a. cul-de-sac at various distances above the bifurcation of the trachea and below the larynx. The pouch is usually but not always dilated. Its walls are often hypertrophied, evidently the result of ineffectual attempts to swallow amniotic fluid. In ninety-six of one hundred and thirty-six cases reported by E. D. Plass and reviewed by I. S. Hirsch there was an esophago-tracheal fistula opening into the respiratory tube.

Classifications of this condition are many but we prefer that of Griffith and Levenson, which with slight changes, so as to be given in the order of the frequency of its occurrence,

is as follows:

- 1. Obliteration of a portion of the Esophagus with tracheo-esophageal (or broncho-esophageal) fistula.
- 2. Congenital dilatation. It is limited to the portion just above the diaphragm. This condition may lead to a secondary diffuse dilatation involving the entire length of the esophagus.
- 3. Obliteration of the esophagus in only a part of its extent unaccompanied by fistula.
 - (a) Only the upper portion may be normal.
 - (b) Both upper and lower portions are patoulous, both portions being connected by a more or less distinct muscular or connective tissue band.
 - (c) Present as a cordlike structure.
- 4. Stenosis. It may be caused either by a fold of mucus membrane or a narrowing involving the entire wall of the Esophagus
- 5. Tracheo-esophageal fistula without any other lesion of the Esophagus.
- 6. Partial or complete doubling of the Esophagus involving the entire wall of the Esophagus.

The usual symptoms are typical and should be recognized. The child at birth may appear perfectly normal and attempt to nurse, but the milk will not be swallowed. It may be asphyxiated at birth due to mucus in the nose The child may have choking and throat. attacks due to an accumulation of frothy mucus-saliva which cannot be swallowed. All liquids are regurgitated after a small quantity has been taken. One is unable to pass even the finest catheter (the length of the obstruction varies but the catheter is usually arrested at a point 9.0-11.0 cm. from the alveolar margin). The stomach is seen to inflate with each inspiration. Meconium is passed, but there is no change in the evacuation even though the child lives for several days. Examination of the meconium does not reveal any lanugo hair. Breath sounds are more audible than normally over the abdomen. Rattling, whistling, or noisy respiration frequently occurs. Cyanosis, which appears periodically, is a constant feature. Urine is voided as usual, but after a few days becomes scanty in quantity. There is a progressive loss of weight frequently marked by elevation of temperature (inanition fever).

These cases invariably terminate fatally, the duration of life depending upon the vigor of the child at birth. Death from starvation is certain to occur if the infant is not operated upon. If gastrostomy is done, they almost always die from shock, hemorrhage suffocation, or broncho-pneumonia, the last probably occuring as a result of food introduced into the stomach being regurgitated into the lungs. Jejunostomy would prevent this latter accident because it obviates back-flow from the esophagus into the trachea.

Sometimes there is an incomplete stricture not recognized until the child is grown up. The lumen in these cases being sufficiently large to transmit liquids and even solid foods, but as a result of that stricture the esophagus immediately above it dilates, due to a tendency of part of the meal to remain at that point. Apfel reports such a case in which a number sixteen French catheter would only go down five inches, and even saline would not flow through the tube. The child died two days

after gastrostomy.

In passing it might be of interest to mention that Neuhoff and Ziegler have developed an operation for accidental stricture of the esophagus which might conceivably be used in children with incomplete stenosis. It is a two-stage operation which aims to produce a bed of granulation tissue around the Esophagus. Into this bed a rubber tube can be inserted and allowed to remain until the cut ends of the Esophagus become adherent to the granulation bed, and the granulation bed becomes covered with overgrowth from the Esophageal epithelium.

Morse says that all cases of congenital atresia should be reported, partly because of their rarity, and partly because the symptoms although characteristic are usually misinterpreted and attributed to some other disease.

Case Report

A child nine months old, a patient of Dr. F. E. Johnson was admitted to the hospital because of difficulty in swallowing. There are no brothers or sisters and the family history was not relevant.

The patient was a full term baby, delivered after a normal labor. Inspection at birth had revealed a well developed baby with no obvious abnormalities. It was breast fed without

1095

Volume 31 Number 18

trouble for a few days, and then the child began to have difficulty in swallowing the milk The mother, not knowing what to make of this, resorted to pineling the child's uose and forcing it to swallow After this ordeal the child would often vonut and frequently the vonitus was tinged with blood

Examination disclosed a fairly well developed but poorly nourished, pale, child D'Espines sign was negative. There was no dulness under the sternum nor over the spinous processes, and air entered both lungs well The heart sounds and rate were normal, the abdomen scaphoid, the skin dry, the urinc The tuberculin test was negative. A 6 m m Esophagaseope was easily passed, and constriction was encountered at a distance of 12cm from the alveolar margin admitting a This was passed number twelve bougie several times to dilate the stricture stricture was apparently congenital membrane The opening in the stricture was about the size of a lead pencil. It was easily ruptured and dilated

Two weeks later a six mm-llsophagascope was again passed, and this time the narrowing was encountered at 12em from the alveolar No induration of scarring was ob-The mucosa appeared paler than served normal but was immterrupted. Numbers fivesix-seven English bongies were passed

The next day the child showed a slight re action as a result of the instrumentation. The pulse became rapid, the temperature fluctuated between 100 and 1011/2 degrees for three days The patient was given 21/2 grains of bismuth subnitrate three times a day and the reaction subsided

A few weeks later dilatation was repeated again The 6 mm-Esophagascope was passed through the stricture. This time the child had no reaction

Two examinations were done at the office and a number six Esophagaseope was passed into the stomach without difficulty

At this stage the child refused to cat because of the habit of being fed. It was hospitalized, its routine changed, and the difficulty was eliminated

To date the child is much better able to swallow and vonits only oecasionally

TREATMENT OF UNDESCENDED TESTES BY INJECTION OF PROLAN By ALEXANDER GOLDMAN, MD, AND ABNER STERN, MD, BRONX, NEW YORK, NY

Real at a n ceting of the Clinical Society of the Bronx Hospital on March 13 1933

THL testes develop in pairs from the primitive bodies situated behind the peritoneum on a level with the third lumbar vertebra The migration of the testieles from that position on through the inguinal eanal into the serotum, commences about the sixth month of foetal life, and is completed at the time of birth

Retention of the testis is said to occur, if this gland is arrested at any part in its migration from the abdominal cavity to the serotum

Until recent years, the non-descent of the testes was explained on a mechanical basis Treatment of this condition was recommended only in cases where symptoms arose such as tenderness or pain. The treatment obviously was purely mechanical, and consisted of surgical interference namely, of stretching the cord and implanting the testis into the serotum

Other investigaters had noted the great increase in the interstitial cell mass as birth approached and noted that after birth this increase was lost and was not entirely regained until near puberty

In his studies on the action of the anteriorpituitary-like hormones of pregnancy urine (the basis of the A-Z test), Engle observed that the testes of immature monkeys were very similar in structure to the testes of the human new born Under treatment with the hormones from pregnancy urine the testes doubled in weight, with an increase of from four to ten times in the size of the interstitial cell mass. The preparations used have eansed no acceleration of spermato

genesis, the action being mainly directed to the interstitial cells.

When immature monkeys are treated with the gonad stimulating fraction from human pregnancy urine, the testes not only increased in size, but the scrotum became turgose and oedematous. While this was occurring, during two or three weeks, the testes descended from the level of the external inguinal ring well into the scrotum. It was suggested by Engle that under normal conditions, this response was one of the factors involved in the normal descent of the testes in the infant male human.

Applying Engle's work on monkeys to humans, we decided to treat cases of undescended testes by injecting them with the hormones obtained from the urine of pregnant women.

The following is the report of two cases.

Case H. P. Age 12 years. He had measles and tonsilitis as a child. Tonsils were removed at the age of three. Hermiotomy was done at the age of five. At that time was told that "his testicles had not developed."

Physical examination showed a boy whose weight was 132½ pounds, and height 5 feet, 3½ inches. The boy was feminine in appearance, skin fair, well built, stout, shoulders round, chest soft and protruding, fleshy hips, abdomen large and pendulus at the lower parts. He was also phlegmatic. There was scant pubic hair, the scrotum small, the right testis small, the left testis was not in scrotum nor felt in the inguinal canal.

Treatment was started June 12, 1932. Patient was injected with 100 rat units of Antuitrin S (hormone from urine of pregnant women) three times a week. Medication by mouth consisted of three grains of extract of anterior pituitary, and one grain of the whole gland twice a day, as well as 1/10 grain of thyroid once a day.

The boy now weighs 130 pounds, a loss of $2\frac{1}{2}$ pounds, and is 5 feet, 5 inches tall, a gain of $1\frac{1}{2}$ inches. The abdominal fat has decreased considerably, his hips are flattened. There has been a great increase in pubic hair, and the scrotum is greatly increased in size. The size of the right testis is at least three times its previous size, and the left testis is easily palpable, moving freely up and down in the canal, and of considerable size. His general appearance is more masculine, his morale is greatly improved, and he feels encouraged.

Case J. G. A boy of 15 years. As a child he had chronic colitis, measles, whooping cough, German measles, chicken-pox, and he had his tonsils removed at the age of seven. His weight was 88 pounds, and his height 4 feet, 9½ inches. He was fair, blond, slim and small. His voice was high pitched, he was nervous and cried readily. His right testis was undescended, his left testis was in the scrotum, but small. The scrotum was small in size, and there was no visible hair on the pubis.

Treatment was started June 13th, 1932, and consisted of injections of 100 rat units of Autuitrin S, given three times a week. After one week's treatment it was noticed that the scrotum had increased considerably in size, and the right testis was now palpable in the scrotal sac. This boy failed to appear regularly for the injections, sometimes missing treatments for several weeks at a time. He now weighs 92 pounds, a gain of four pounds, and is 5 feet tall, a gain of 2½ inches. Both testis are now in the scrotum, his left testis considerably enlarged and there is a great amount of pubic hair. His voice is not so high pitched, and he is not so emotional.

The results obtained in these two cases are very encouraging. Not only was there a descent of the testicles in both of these cases, but there was an increase in the size of the testicles, and a definite change in the secondary sexual characteristics. By analogy with Engle's work on monkeys, it seems very likely that the increase in the size of the testicle was due to a hypertrophy of the interstitial tissue of the testis and the change in the secondary sexual characteristics was a result of the increase in the interstitial gland substance, with an ensuing increase in male sex hormone.

Why is it important to cause these retained testes to descend? What particular harm is there in permitting these retained testes to remain where they are arrested?

First, evidence has accumulated to show that these ectopic testicles are apt to become the seat of malignant growths later in life.

Secondly, spermatogenesis will never take place in a testicle that is not in the scrotum.

Thirdly, testicles that are ectopic are apt to atrophy, and the interstitial gland secretions are diminished, or may entirely disappear. These effects are probably due to the higher temperature in the abdomen than in the scrotum. This difference in temperature may be as great as 8° C. Degeneration of the testes is known to occur where they are subjected to a constant temperature of 38° C.

Surgery, in our experience, has been very unsatisfactory. In those cases where the testicle was brought down into the scrotum, atrophy of the testis usually occurred.

While it would be fool-hardy to generalize from the results obtained in just these two cases treated with prolan, the results have been so striking that we felt a preliminary report was justified.

A larger series of cases is at present under treatment at the Endocrine Clinic of the Bronx Hospital, and we hope to report the results of treatment of the member of this group in the near future.

The authors wish to thank Dr. Earle T. Engle, and Dr. Raphael Kurzrek for their kind cooperation in the study of these two cases.

ASPIRIN TEST TO DETERMINE THE ADVISABILITY OF REMOVAL OF FOCI IN RHEUMATIC CONDITIONS

By HEINRICH F. WOLF, M.D., NEW YORK, N. Y. From the Department of Physical Therapy at Mt. Sinal Hospital.

OR several years I have, in connection with the Laryngological and Dental Departments of Mt. Sinai Hospital, carried on studies into the relation between focal infections within the mouth, and rhenmatic diseases, and they have led to the development of a method of determining whether or not the removal of infected tonsils or teeth would be likely to give relief from rheu-Such an indication was found in the reaction of the patient to aspirin.

These investigations have revealed many rheumatic patients whose tonsils had been removed, or teeth extracted, without any relief from their When these patients were given rheumatism.

aspirin, not one was relieved.

No one would expect relief from pain by aspirin in a case of tuberculosis of a joint, or a gonorrheal or syphilitic infection, or a metabolic, static or traumatic arthritis. On the other hand, aspirin is known to give relief in infections due to the streptococcus viridans and hemolyticus, and to the staphylococcus group, which are the pathogenie organisms most frequently found in the foci above the neck.

It is now our rule that any patient complaining of a condition called rheumatic receives 10 to 15 grains of aspirin once. If he does not react with relief of pain within an hour, the extraction of a tooth or a tonsillectomy is not advised, no matter what the oral pathology may be. This does not mean that abscessed teeth should not be extracted as a positive danger, but the patient in such cases should be told that a relief of his pain is doubtful.

Many physicians advocate the extraction of devitalized teeth without visible pathology as a routine procedure in all cases of arthritis. It is well known, however, that these extractions often prove futile. We do not advocate an extraction if the patient does not respond to salicylates. If he does, and if a number of teeth are devitalized or show improper root fillings without abscesses or rarefications, we advise removal of the fillings of the roots and the examination of the root bacteriologically. If an infection is present the tooth should be extracted, if it can be replaced easily. If the tooth is technically important (bridge work, plate), an effort should be made to cure the infection without removing the teeth. It is obvious however that in those cases which already show structural changes in the joints, no cure can be expected from extraction alone without further treatment, but the exacerbations are likely to subside.

THE EXTERNAL EXAMINATION OF THE EYE IN THE DIAGNOSIS OF GENERAL DISEASES

1. VISION, POSITION OF THE EYE IN THE ORBIT AND THE EXAMINATION OF THE EYELIDS.

By CONRAD BERENS, M.D., and JOSHUA ZUCKERMAN, M.D., NEW YORK, N. Y. The first of a series of three papers read before the Dallas Southern Clinical Society, Dallas, Texas, April 1, 1931.

A. Vision

B. Position of eye in the orbit

(3) Redness

LTHOUGH physicians appreciate the im-A portance of certain eye symptoms and signs in the diagnosis of systemic diseases, professional practice usually prevents their studying the eye in ophthalmologic clinics and reading textbooks of ophthalmology. The purpose of this outline is to point out those phases of the external examination of the eye which have proved valuable in the diagnosis of general diseases.

- (4) Edema
- (5) Pigmentation
- (6) Hemorrhage (7) Motor anomalies
 - a. Inability to close eyelids
 - b. Inability to open eyelids blepharospasm-t witching
- (8) Narrowed palpebral fissure
- (9) Widened palpebral fissure

A. Vision

It is always important to determine whether vision is present, whether it is normal or defective; if defective, what is the cause. In young children the closure of the eyelids which occurs when a bright light is projected into their eyes may be utilized to determine whether vision is present. Poor visual acuity is not necessarily due to local or general pathologic conditions but may be due to

near-sightedness, far-sightedness, or a combination of both. To determine whether glasses will improve vision, have the patient read the test chart at a distance of twenty feet through a one millimeter pinhole. If the vision is improved practically to normal with the pinhole, glasses are usually indicated. If the vision is not improved, a careful search should be made for corneal opacities, lens changes, and diseases of the media or fundi produced by local or general diseases, such as tuberculosis, syphilis, diabetes, hypertension, focal infection or brain lesions.

B. Position of the Eye in the Orbit

Special notice should be taken of the position of the eye in each orbit and the relation of one eye to the other. Normally the position of the eyeball in the orbit is such that a vertical line dropped from the upper to the lower orbital margin is tangential to the cornea. Variations have been found in apparently normal individuals

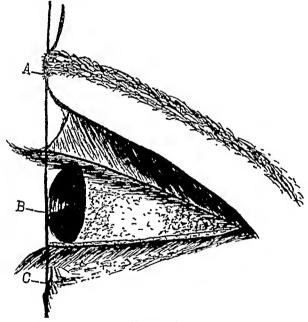

FIGURE 1

This diagram shows that in the normal position of the cye a vertical line dropped from the upper to the lower orbital margin is tangential to the cornea. A, upper orbital margin; B, cornea; C, lower orbital margin.

in which the cornea was one centimeter anterior and in other cases one centimeter posterior to this position. If one eye or both eyes apparently protrude it is important to exclude unilateral or bilateral high myopia (near-sightedness), for in this condition the anteroposterior diameter of the eyeball may be six or eight millimeters longer than normal and will give the impression of prominence of the eyes.

(1) Unilateral Exophthalmos.—This condition is usually caused by disease of the orbit or it may

occur as a secondary manifestation of disease of the surrounding structures.

- (a) Syphilis and tuberculosis of the orbital bones and periosteum may cause exophthalmos. We have seen one case of displacement of the eyeball downward, nasally and somewhat forward as a result of tuberculosis of the lacrimal gland.
- (b) Tumors of the orbit, particularly sarcomas, may displace the eyeball forward. Papilledema (edema of the optic nerve head) is a common sign in tumors of the orbit. The deeper the tumor is placed in the apex of the orbit, the more marked is the visual disturbance and the more common are limitations of movement of the eyeball.

Figure 2

A case of unilateral exophthalmos produced by angioma of the orbit.

- (c) Extension of inflammation from the uasal accessory sinuses causing unilateral exophthalmos is not uncommon. In acute cases there is redness of the eyelid, edema of the conjunctiva, and occasionally papilledema or papillitis. In chronic cases little, if any, inflammation may be noted and it is possible for a marked displacement of the eye to occur without serious disturbance of binocular vision, i. e., simultaneous vision with both eyes.
- (d) Thrombosis of the cavernous sinus produces a varying degree of exophthalmos which is first unilateral and then bilateral. The cause is usually infection or traumatism and the communication between the vascular sinuses by means of the circular sinus explains why exophthalmos is so often bilateral. Exophthalmos is caused by venous engorgement and edema of the loose cellular tissue in the orbit.
- (e) Thrombophlebitis of the orbital veins may be responsible for protrusion of the eyeball. It is sometimes metastatic in the course of or after scarlet fever and other infectious diseases. In some cases it seems to be associated with infection of the nasal accessory sinuses and dental

infections. Inflammation of the orbital vein may be associated with injury. Terrien reports a case in which unilateral exophthalmos seemed to be secondary to thrombo-phichitis, the result of the lodgment of a revolver bullet in the roof of the left orbit.

(f) Inflommotion of Tenon's eapsule, sometimes noted in influenza and rheumatism, may

also produce unilateral exoplithalmos.

(g) Hemorrhages in the orbit, both traumatic and nontraumatic, may give rise to unilateral exophthalmos.

(h) Ponophthalmitis (inflammatory involvement of the entire eye) usually produces rather

marked protrusion of the eyeball.

(i) Pulsating exophtholmos is often attributable to rupture of the internal carotid artery into the cavernous sinus, creating an arteriovenous aneurysm.

(j) Intermittent exophthalmos2 is noted when varicose veins are present in the orbit and may lead to prolapse of the eyeball following physical strain either with or without hemorrhages in the orbit.

(k) Tenotomy and parolysis of the oeular muscles may produce a mild degree of exophthalmos.

(1) In Basedow's disease unilateral exophthalmos may occasionally be seen.

- (2) Biloterol Exophtholmos. Probably the commonest cause of bilateral exophthalmos is (a) Basedow's disease, although (b) myopia, (e) cranial anomalies, and (d) bilateral tumors of the orbit should be considered. Bilateral exophthalmos related to (e) sinus thrombosis has been mentioned. Associated symptoms in Basedow's disease are lagging of the upper eyelids when the patient looks down (von Graefe's sign), infrequent closure of the eyelids (Stellwag's sign), and tendency to divergence of the visual axes with insufficiency of convergence (Moebius' sign), i.e., inability to bring both eyes to fixate an object held at three inches from the eyes.3
- (3) Enophthalmos or sunken eye may be produced (a) by operations on the ocular muscles and is associated with decrease in width of the palpebral fissure. It also occurs in (b) the aged, (c) extreme emaciation, (d) paralysis of the sympathetic (e) congenital defects and (f) as the result of traumatism.

C. The Eyelids

(1) Scors, just above the nasal angle of the eye unless they are due to trauma, are usually the result of infection in the ethmoid cells. the scar lies just below this point it is probably due to inflammation of the lacrimal sac. Scars along the upper outer margin of the orbit sometimes result from tuberculosis of the orbital bone.

(2) Alrophy and relaxation of the upper eye-

lid so that the skin extends down over the eyelashes of the upper eyelid (called blepharochalasis) is usually a late sign in angioneurotic edema of the eyelid.

(3) Recurrent attacks of slight redness and swelling, particularly of the upper eyelids with slight scaling and itching, are often associated with chronic infection in the nasal accessory sinuses and may be an expression of bacterial allergy.

(4) Edemo of the eyelid is frequently caused Noninflammatory by a hordcolum (stye). edema may be of diagnostic importance in beginning heart failure, nephritis and myxedema.

(5) Marked pigmentation of the lower eyelid is a common finding in elderly people but may also be an early sign in Basedow's disease and Addison's disease.

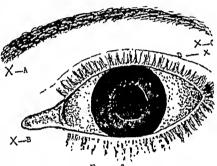

FIGURE 3

Scars in the region of the eyelids produced by: A, discase of the ethinoid cells; B, disease of the lacrimal sac; C, inflammation of the Lacrimal glands; D, tuberculosis of the margin of the orbit.

(6) Hemorrhage into the eyelid is commonly caused by direct traumatism. It also occurs in at least one-third of all cases of fracture of the base of the skull,

(7) Motor anomalies of the eyelids and their differential diagnosis.

Inability to close the eyelid is due to paralysis of the facial nerve which supplies the orbicularis " : splincter muscle of the is the result of an injury

and cause win be apparent. Blepharospasm, i.e., spastic closure of the eyelids, is often noted in inflammations and injuries of the cornea. Dental infections, disease of the nasal accessory sinuses and of the mucous membrane of the upper respiratory tract, snow blindness, chorea, epilepsy, hysteria, and tetanus are common causes of blepharospasm. Central causes of blepharospasm are meningitis and tumors. Clonic spasin (twitching) of the fibrilla of the orbicularis palpebrarum muscle, especially of the lower eyelid, is commonly seen in overworked, nervous people,

especially those who have poor converging power or uncorrected or improperly corrected refractive The blinking which is often noted in children has, in our experience, often been associated with chronic conjunctivitis and chronic nasal infections. The proper correction of refractive errors (i.e., proper glasses), the treatment of local and focal infections, and the correction of anomalies of the eye muscles have apparently given relief in certain cases.

If inability to open the eyelid has existed from birth, congenital ptosis, which is usually bilateral,

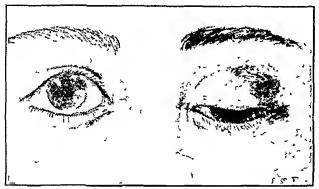

FIGURE 4 Congenital ptosis of the left eyelid.

will be thought of, and absence of the levator palpebræ superioris muscle will be suspected. Acquired ptosis is usually the result of lesions of the third nerve which supplies the levator palpebræ superioris muscle. If the branches of the third nerve to the extra-ocular muscles are also involved, the eyeball will be turned downward and outward by the unopposed action of the ex-

ternal rectus and superior oblique, which are the only two extra-ocular muscles not supplied by the third nerve. Syphilis and traumatism are common causes of lesions of the third nerve Unilateral ptosis or drooping of the upper eyelid may be produced by injuries, abscesses, hemorrhages, tumors and syphilitic periostitis which directly affect the levator muscle of the upper eyelid. Cortical, as well as nuclear lesions, may produce unilateral ptosis. The nuclear lesions may be brought about by hemorrhage, multiple sclerosis, infectious diseases, tabes, cerebial syphilis, and progressive paralysis. Chronic progressive ophthalmoplegia externa is a condition which often commences in childhood with unilateral or bilateral ptosis and usually progresses to complete paralysis of all the extra-ocular muscles In myasthenia gravis pseudoparalytica and in hysteria, ptosis is usually bilateral.

(8) Narrowed palpebral fissure.—Ptosis of the eyelid caused by lesions of the sympathetic and third nerves should be differentiated from apparent ptosis in patients with trachoma, vernal catarrh, syphilitic involvement of the farsus, and

edema resulting from nephritis. (9) Widened palpebral fissure.—Psychic influences may cause a change in the size of the palpebral fissure. Everyone is familiar with the stare due to widening of the palpebral fissure in Increased size of the palpebral fissure may be caused by a large myopic eyeball, abscess in the orbit, retrobulbar tumors, tower head, and arteriovenous aneurysms affecting the cavernous Overaction of the superior palpebral muscle of Müller or paresis of the orbicularis palpebrarum muscle may also result in a widened palpebral fissure.

FOOD HYPERSENSITIVENESS

By W. C. SPAIN, M.D., NEW YORK, N. Y.

From the New York Post Graduate Medical School and Hospital of Columbia University Presented before the Cumberland County Medical Society, Portland, Maine, November 25, 1932

FEW years ago it would have been a rash individual indeed who would have thought Food Hypersensitiveness a subject which concerned greatly those working in such diverse fields as pedriatics, rhinology, internal medicine, surgery and ophthalmology. And yet we know today that all these branches of medicine and many more are concerned, with food sensitization.

So great has been the interest in this phase of immunology, that the idea has been overworked with the consequence that many clinical condi-

tions, whose etiologic basis is vaguely understood, if at all, are classed as "allergic" for want of a better diagnosis. A great deal of confusion has thus arisen concerning such terms as hypersensitiveness, allergy, atopy and anaphylaxis.1 first task that confronts us therefore is the somewhat didactic one of giving definitions. broad term of hypersensitiveness under which are grouped allergy, atopy and anaphylaxis is used to describe the characteristic condition which arises in a small percentage of individuals, from contact with a minute amount of specific excitant

usually protein.

Hypersensitiveness occurs both in man and in lower animals, the condition in man being termed allergy or atopy; and in the animal, anaphylaxis. The reasons for this separation of the human and animal forms need not be discussed here. However, it may be stated that anaphylaxis is quite different from hypersensitiveness in man in that it is always artificially produced, never occurs spontaneously, is temporary, and is never inherited.

The recognized forms of hypersensitiveness in man are hay fever, bronchial asthma, allergie coryza, urticaria, angioneurotic oedema, migraine, certain forms of eczema and of acute gastroenteritis. All of these conditions are classified un-

der the designation of "allergy."

Hay fever, bronchial asthma, allergic coryza and certain forms of gastroenteritis, also are classified under the term "atopy," largely because in them a definite familial tendency has been proven, the majority of cases having a family history positive for hypersensitive complaints in the antecedent and collateral members of the family.2, 2, 4, 5 The study of a great number of individuals with lustories positive for asthma or hay lever has made it possible to estimate not only the number of children in a family who may develop hay fever or asthma, but the approximate age at which symptoms will appear. Allergie eczema (neurodermatitis) slould probably be classed under "atopy," since also in this condition inherited tendencies have been demonstrated.

With the exception of seasonal hav fever. which is in reality, a form of allergic coryza, all of the clinical allergic conditions mentioned may be manifestations of food sensitiveness. erally considered atopic, are the acute gastrointestinal symptoms so easily mistaken for those of a surgical abdomen, with nausea, vomiting, distension, epigastric or abdominal pain, diarrhea and collapse, these symptoms following the ingestion of a specific food excitant. Vague, less well defined chronic abdominal complaints, such as bad breath, anorexia, constipation, dull abdominal pains, have also been classified as allergic.7 Epilipsy,8 arthritis,9 acute bladder disturbances,10 uterine irregularities,11 herpes simplex,7 gastric ulcer,12 episcleritis,13 pruritus ani,7 fever,7 malaise, malnutrition, and many other complaints have been classed by varied investigators under this heading.

Age Incidence.—The majority of cases of food sensitiveness occur in early life. From a study of 200 cases of bronchial asthma it was found by intracutaneous test that only individuals of three years or younger developed symptoms from foods alone. After that age the inhalant substances such as pollens, dusts, feathers, etc., gradually replaced the food sensitiveness, so that by the age

of 10 to 12 the majority of patients had lost the food reactions elinically, although the skin sensitiveness often remained. In only five per cent of adult astlimatic patients was it possible to demonstrate a food sensitiveness as the sole offending factor. Stuart and Farnham,14 studying infants and children, found that in the second year of life, the greatest incidence of food sensitiveness occurred, the percentage rapidly decreasing after that age. In a study of 160 cases of infantile eczema, of which 110 gave positive reactions to food tests, Smythe, Bain and Stallings15 found that 105 patients or 65% had onset of symptoms before the sixth month and 14% before the twelfth month. These figures agree closely with the findings in similar cases by O'Keefe and Rackemann.18

The explanation for this sensitization to foods early in life is unknown to us. Formerly it was thought that this condition was due to a defective gastrointestinal membrane which allowed unaltered protein to be absorbed into the circulating blood, thus sensitizing the individuals. That such absorption occurs normally however, has been shown by several investigators, chiefly by Du Bois, Schloss and Anderson,17 who found strong proof of the absorption of unaltered protein in the blood of nonsensitive infants, and by Brunner and Walzer18 who showed that unaltered protein could be normally absorbed into the circulation within a half hour of ingestion of the food.

Diagnosis .- The methods used in determining sensitiveness to foods are (1) the history, (2) the cutaneous tests, and (3) the elinical tests. An accurate history is of great importance since often it furnishes the chief means of diagnosis. Several points particularly should be emphasized. First, the establishment of the atopic nature of the attacks, since it is in this condition that the cutaneous tests are of greatest value and the results of treatment more likely to be successful. The presence of bronchial asthma, hay fever. atopic coryza, or eczema, in the patient or in the antecedent or collateral family history, furnishes strong evidence of the atopic or inherited nature of the food reaction. A comprchensive family history should therefore be obtained.

A second point of importance is a description of the attacks—the frequency, intensity and duration, and relation to meals. The attacks may be acute or explosive in nature, with periods of normal behavior between paroxysms, their occurrence depending on the occasional contacts with the specific excitant, or they may be cumulative, being due, not to foods infrequently eaten but to the gradual storing in the body of toxic products from some food substances present daily in the diet, but not apparently irritating until the limit of tolerance has been reached. Any periodicity or regularity of the attacks should be obscryed, and their relation to daily, weekly or monthly rou-

tine of the patient noted. In a young woman who had suffered for years from migraine each Monday, the causative factor, egg, was established not by skin test, but by discovering that only at Sunday breakfast, were eggs eaten. In the acute type of attacks the reaction time between ingestion of the food excitant and the symptoms varies in different individuals from a few seconds, to several days, a condition which adds to the difficulty of diagnosis. Generally, however, the more acute the attack, the shorter the reaction time. For instance, symptoms of utmost gravity, dyspnoea, cyanosis, and collapse, have been known to develop in egg sensitive children the moment a minute amount of egg has come into contact with the lingual and buccal mucosa, long before ingestion could possibly occur. Indeed actual contact with the excitant is unnecessary for the development of symptoms in exquisitely sensitive cases. The odor emanating from such foods, as fish, celery or onion will alone be sufficient to produce, in susceptible persons, violent asthmatic and coryzal attacks. A patient seen at the clinic was so sensitive to fish, that merely passing a fish market would cause severe attacks of asthma. Another patient, a Michigan physician, would suffer severely from asthma whenever entering a dining room where celery was on the table, or whenever driving past celery fields, even during nonpollenating seasons. There are also food cases so exquisitely sensitive that merely contact of the food with the unbroken skin will produce severe symptoms of asthma, urticaria or dermatitis. A physician working in the Asthma Clinic at the Post Graduate Hospital is so sensitive to egg that rubber gloves are worn whenever the testing of egg extract upon a patient is necessary. Many cases, especially in kitchen workers, have been recorded where it has been necessary to peel potatoes or onions under water, to prevent reactions.

Even in the less explosive types of food intolerance where the reaction time is longer and the symptoms more chronic in type, a close questioning may reveal the causative factor especially in children, where the history of an aversion to a particular food or foods is often highly significant. Such a dislike may frequently indicate the specific excitant, although the child's attitude, nature's protective effort, may be interpreted by the parent or physician as merely a whim or fancy. There are many asthmatic and undernourished children, who, sensitive to milk or egg, are forced to take these foods because they are "good" for them, whereas in reality these substances are the very causes of the complaints.

A third point of importance in the history is the consideration in detail of the patient's usual diet; the amount of milk consumed daily; the number of eggs; the varieties of meat, fish, fruits, vegetables and nuts; the amount of chocolate and cheese; the use of coffee and tea. Any food or beverage used intemperately should be suspected. A young woman desiring to gain weight was recently seen for urticaria of three months standing, coryza and loss of weight. She gave a history of drinking two quarts of milk daily. Cutaneous tests were negative, but with the simple removal of milk she lost her urticaria and coryza and gained rapidly in weight. In another case, a young nurse, suffering from asthma, admitted drinking large quantities of black coffee. Removal of coffee from the diet completely relieved the condition. In this case the diagnosis could be verified by positive skin test.

In chronic food sensitizations such as urticaria and migraine where the history and cutaneous tests offer little aid, it is of benefit to have the patient keep a complete diary of his food intake, which can be studied in relation to the attacks. Frequently in this way only, a clue to the causative factors can be obtained.

Cutaneous Tests .- The importance of cutaneous testing as an aid in determining the diagnosis in allergic conditions is well established, and the procedures employed, both intracutaneous and scarification methods, are too well known to warrant describing them here. Permit me however, to direct your attention to several important facts in this connection: (1) positive food reactions are most frequently elicited in the atopic group of food cases-that is, in those presenting in themselves or in their family, a history of asthma, hay fever, atopic coryza or atopic eczema; (2) negative food reactions upon test, with positive clinical histories are common, particularly in urticaria, angioneurotic oedema, migraine and the vague clinical forms mentioned above; (3) many false positive reactions are obtained which cannot be verified and cannot be explained. The reasons for the negative reactions are only partially known. Cooking may so alter the foods that testing with the unheated protein of the diagnostic extracts may be inconsistent. Extracts of heated protein have been even more unsuccessful. Further, the mechanism of food sensitivenes may differ in the nonatopic group of food cases. skin sensitizing antibody or the reagin, characteristic of the atopic group cannot usually be demonstrated in them. Also the time element or incubation period may be responsible. It is unusual to obtain an immediate positive wheal upon test with the extract of a food that in the patient requires hours to cause apparent symptoms.

In many patients with thickened or eczematous skin the results of the cutaneous tests are unsatisfactory. In these cases the method of passive transfer has been most successful. Prausnitz and Küstner¹⁰ found that the sera of atopic individuals contained antibodies that would specifically sensitize the skin of a normal person to the excitants responsible for the patient's condition. By

employment of this principle it is possible to test local skin areas in the normal individual made sensitive temporarily, with the serum of the susceptible patient. The importance of this method of testing in infants and children was first emphasized by Walzer and Kramer.²⁰

Clinical Tests.—In cases where the skin tests prove negative, but where the history suggests the causative factor, a clinical trial is of value, the suspected food being given after a period of abstinence and when the patient is symptom-free. Care must be taken to avoid excessive amounts of

the foods thus investigated.

The elimination diets of Rower are based upon the trial and error procedure, the patient being placed upon a severely restricted diet until it is proven that it can or cannot be tolerated. If the patient loses his symptoms upon the menu selected, additional foods are cautiously and slowly added. Successful results have been obtained in many perplexing cases by this method, but it is often difficult to secure the complete cooperation of the patient due to the necessary rigidity of the plan.

The Chief Offending Foods.—While experience has shown that all varieties of foods must be suspected as excitants of food hypersensitiveness, there are several that are much more prominent than the rest as regards both incidence and ability to produce clinical symptoms. Investigators generally agree that these are egg, wheat, milk, fish and shellfish, meats, chocolate and nuts.

Egg is probably the most important of all foods in this connection, particularly in infancy and in early childhood, not only because sensitizations are comparatively frequent but also because the symptoms produced may be most severe. Not only asthma, coryza, urticaria and migraine are often caused by this excitant, but also infantile eczema and neurodermatitis, not only from ingestion but also from contact with the unbroken skin, as noted above. Such egg intolerance can apparently be inherited as in the family described by La Roche and Richet, "where gastrointestinal symptoms from egg were known in four generations.

Testing with this substance requires great caution, particularly in infants, since many cases of extreme sensitiveness exist. Dilutions of whole egg white, one part in 1,000,000 and one part in 100,000 are employed, separation of the various protein fractions, albumin, globulin and mucoid, being nnnecessary. Reactions to extracts of chicken meat and of chicken epithelium (feathers) are frequently obtained in egg sensitive cases. Testing with yolk extracts have been generally discontinued, since apparently egg cases are more sensitive clinically and by test, to the white.

Where egg is to be avoided in the diet the difficulties are many, due to the numerous ways in

which it is employed. Pastry, cake, wasses, macaroni, noodles, custard and ice cream are made with important amounts of egg. Pies and breads are glazed with egg. Fondants and soft centered candies contain it. It is often employed in making meat cakes and croquettes. Even the breast fed infant may obtain egg through the mother's milk.²² Egg white is used as a "binder" in a variety of water color paints known as "Tempera." A case is recorded where eczema from egg developed from this source.

Wheat may cause symptoms of asthma, coryza, migraine, urticaria and eczema not only by ingestion and contact as does egg, but also by inhala-Bakers, wall-paperers, grain dealers and millers have been described as cases of such wheat sensitization, asthma and coryza being the usual symptoms. Such inhalant cases are difficult to treat successfully and frequently a change in occupation may be necessary. A patient may have any one or any combination of symptoms as a result of wheat contact. Other cereals similar in action to wheat are rice, barley, corn, rye and oats. Buckwheat, although botanically unlike, is placed here. It should be emphasized that it has been the cause of many severe clinical reactions and extreme caution must be used in testing for sensitiveness to it. Where wheat or other cereals must be eliminated from the diet it should be recalled that coffee substitutes are chiefly cereal. Extracts of the whole grain are used in testing for wheat sensitization.

Milk is an important offender particularly in infants and children. Symptoms identical in variety with those caused by egg and wheat are found, although rarely produced except by ingestion. Of the milk proteins, lactalbumin is the most important, as an excitant. Since heat destroys this fraction, boiled milk can be tolerated by many milk sensitive individuals. Other milk sensitive patients, however, must avoid all forms of milk and milk products, such as cheese, buttermilk, cream, condensed, evaporated, powdered and malted milks. Chocolate products often contain milk. Cream soups, custards, ice creams and varieties of candies must be often eliminated from the diet. In infants, milk substitutes as Soybee,28 or goat's milk, fresh or canned, may be Tests for milk sensitiveness are usually made with decaseinated milk extracts. Extreme sensitiveness is less frequent to milk than to egg.

Fish and shellfish are notorious as causing violent urticaria, angioneurotic oedema, asthma and acute gastrointestinal attacks, although other clinical forms are found. In very sensitive cases, severe symptoms can be produced by inhalation, as in the fish sensitive girl mentioned above. An open -lue pot warming upon the stove has been known to be the source of asthma in a cabinet maker's assistant, sensitive to fish. Tests with the extracts of fish and of glue, a fish collagen, must be performed with greatest caution, since

many cases are very highly sensitive.

Nuts are excitants by ingestion chiefly, causing severe coughing attacks, asthma and skin lesions. Some of the most violent and sudden attacks of asthma have been produced by members of this group, particularly almond, brazil nut, walnut and pecan. Coconut, hazelnut, pistachio and chestnut are less frequent offenders. Peanut is usually classed here, although it is a legume and more closely related to the peas, beans and lentils. There is a common factor present among the nuts, seeds and legumes so that sensitization may exist in nut sensitive cases also to mustard, beans, peas, cottonseed and flaxseed.

Chocolate and cocoa are frequent offenders, causing coryza,²⁴ asthma and urticaria chiefly. Removal of these substances from the diet is

comparatively simple.

Meats, particularly pork, beef and fowl are occasional causes of clinical symptoms. As noted above, egg sensitive cases are frequently allergic in a lesser degree, to fowl. It should be remembered that in pork sensitive cases not only bacon, ham and sausage must be considered, but lard in foods prepared with this shortening.

The vegetables are infrequent causes of allergic reactions except for a small group including celery, onion, white potato, green pea and beans. Asthma, coryza, urticaria, angioneurotic oedema and gastrointestinal symptoms are among the clinical conditions described as developing, not only by ingestion, but by inhalation, as in the case of the celery sensitive physician, previously described, and by contact with the unbroken skin as in the case of those described as sensitive to potato peel. Dermatitis has been reported not only from handling raw string beans and raw tomatoes, but also from contact with the leaves and stems of the plants.

Fruits are generally of minor importance as allergic excitants, although clinical reactions to apple, pineapple, peach, pear, strawberry, melons and the citrus fruits are fairly common. Orange is probably the fruit most frequently responsible for symptoms in children and infants. As in the case of the vegetables, the attacks of asthma, coryza, urticaria or angioneurotic oedema, eczema, migraine and gastrointestinal upsets may occur from inhalation and contact with the skin, as well as from ingestion. Frequently with vegetables, as potato and tomato, as well as with fruits as apple, peach, or pear the rind, skin or seeds may be the offender, the remainder of the vegetable or fruit being harmless to the patient.

Spices, and the essential oils used as flavorings such as oils of wintergreen, spearmint, peppermint, sassafras. clove, etc., must be mentioned. Mustard, blackpepper and vanilla are important excitants in this group. Not only by ingestion but by cutaneous contact in the form of plasters,

mustard is a disturbing factor. As previously mentioned, mustard sensitiveness is frequently associated with sensitiveness to nuts and to seeds such as cottonseed and flaxseed. These latter two substances must also be considered as foods, since the former is used commonly as a salad oil and as a shortening, and the latter as a laxative in some health breads and breakfast foods. In cotton-seed- and flaxseed-sensitive cases, the source of the excitant may be the milk from cows fed upon these substances.

Treatment. - The treatment may be stated simply—removal of the cause. In the adult this may be ordinarily accomplished without interfering with a well rounded diet. In infants and children, however, when egg and especially milk are the specific factors, the treatment is not so simple, since so many articles of diet contain these important foods, and since, in the case of milk particularly, they are so necessary for proper growth. In such instances, attempts are often made to increase the tolerance to a food by repeated carefully determined doses of the offending protein, given either orally or by injection. Schloss²⁵ in 1912 successfully treated an egg sensitive case by oral hyposensitization. Raw egg white may be given daily in water on an ascending scale, beginning with one drop of a 1-1000 dilution. Capsules of egg white, hard boiled, and of egg powder have been used. The injection method is more dangerous since the dosage is difficult to determine and since constitutional reactions easily occur upon overdosage.

Milk sensitive cases and wheat sensitive cases may be treated in the same manner as described for the egg cases, using either the oral or hypodermic method of hyposensitization. the egg cases the dosage should be increased cautiously. It must be recalled that there is a general tendency for the food sensitizations occurring in infancy and early childhood to disappear before puberty, although the positive skin reactions may remain. Frequently, therefore, it is wise not to plan an ambitious and aggressive schedule of oral or hypodermic treatment but to adopt the more conservative policy of regulating the diet; of eliminating or lessening the quantity of the food excitants, and letting Nature slowly correct the condition.

SUMMARY

In conclusion the following facts concerning food sensitization should be emphasized.

1. The clinical forms in which sensitiveness to food may occur are numerous.

2. A comprehensive dietary history is essential to the diagnosis.

3. The positive reactions upon cutaneous test appear chiefly in the atopic group.

4. The principle food excitants are egg, wheat, milk, fish, shellfish, meats, chocolate and nuts.

5 The treatment usually, is to remove the cause

ANATOMICAL CONSIDERATIONS IN RADICAL PHRENIC EXAIRESIS AND SCALENOTOMY

By SAMUEL A THOMPSON, MD, NEW YORK, N Y

THORACIC surgery is on the increase and jet there is comparatively little in the current literature about the details of the actual technique in the various surgical procedures There is little so far as technique is concerned that might be of value to the surgeon mexperienced in this phase of surgery. It is the intention of this article to review the anatomy and topography of the lateral region of the neck and describe in detail a technique for radical phrenic exairesis and scalenotomy which we have been using as a result of these anatomical considera-This technique was developed on the surgical service of Dr Wm F Honan, at the Metro politan and Sea View Hospitals

Considering first the topography, we have several important superficial and deep landmarks The approach to the mun stem of the phrenic is through the posterior triangle of the neck, the boundaries of which are, the posterior border of the sterno mustoid muscle, the anterior border of the trapezius muscle, and the upper surface of the middle of the clavicle. These boundaries can usually be seen and are easily palpated

Another important landmark is the cricoid car tilage at the level of which the phrenic nerve usually lies about inidway between the anterior and the posterior borders of the sterno mastoid

At the level of the cricoid a line drawn from the middle of the sterno mastoid muscle to a point just external to the middle of the clavicle, represents the upper limit of the nerve trunks forming the brachial plexus. Also at the cricoid

level the inferior belly of the omo hyoid muscle crosses under the sterno mastoid muscle and over the carotid sheath, the phrenic nerve and the scalenus muscle. The posterior triangle is divided into an upper occipital triangle and a lower subclavian triangle by the onio hyoid, and should this muscle join its central tendon at a point lower than the cricoid, it makes the subclavian triangle very narrow

At the level of the thyroid cartilage the external jugular vein crosses the sterno mastoid muscle superficially and runs towards the middle of the clavicle The main stem of the phrenic nerve begins on a level withli the upper border of the thyroid cartilage

The outer border of the scalenus anticus muscle corresponds to the outer border of the sterno mastoid muscle

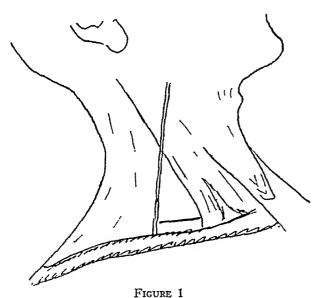

The phrenic nerve arises from the fourth cer vical nerve principally, but has roots from the third and fifth nerves as well, and passes down ward and inward on the anterior surface of the scalenus anticus muscle Occasionally the phrenic has roots from all the cervical nerves and the first thoracic nerve It also may receive accessary fibers from the hypo glossal nerve, from the nerve to the subclavius muscle and from the cer-The phrenic is sometimes a vical sympathetic double nerve and it has been absent in a few recorded instances It is normal, without anomalies or accessary roots in only thirty-five per cent

As the phrenic nerve passes down the neck it it is intiniately associated with the scalenus anticus muscle crossing over the anterior surface

from the lateral to the mesial border. Occasionally it may be found in the substances of the muscle itself.

The brachial plexus emerges lateral to the scalenus anticus, between that muscle and the scalenus medius. The carotid sheath lies medial to the scalenus anticus.

The phrenic nerve in the neck is crossed from above downwards by the inferior belly of the omo-hyoid muscle, the transverse cervical and the transverse scapular arteries and passes behind the subclavian vein to enter the mediastium. From within outwards the phrenic nerve is covered by the prevertebral layer of the deep cervical fascia which covers the scalenae muscles and is a thin aponeurosis in this region. The nerve may be firmly attached to the under surface of this fascia. Superficial to this fascia and overlying the nerve is a layer of fat and loose areolar tissue called the "fat pad." This "fat pad" lies between the middle and deep layers of the deep cervical fascia and contains a few lymph nodes and is transversed by the transverse cervical artery. In this same space but lower down, parallel to, and usually under the clavicle is the trans-

Showing relation of incision to external jugular vein, sternomastoid muscle and clavicle.

verse scapular artery. Superficial to this "fat pad" is the middle layer of the deep fascia which encloses the omo-hyoid muscle, and above this is the superficial layer of the deep fascia which forms the roof of the posterior triangle. It may not be possible to differentiate the superficial and middle layers of the fascia at all times in this region.

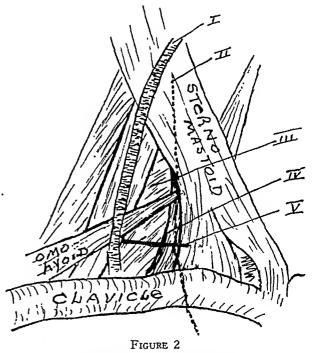

As the scalenus anticus muscle lies behind the sterno-mastoid muscle, this must be considered as a covering together with the skin, superficial fascia and platysma muscle.

Correlating the anatomical points we have the

main stem of the phrenic lying on the scalenus anticus muscle. This muscle lies behind the sterno-mastoid muscle, is covered by the prevertebral layer of the deep fascia, is crossed by the omo-hyoid muscle, the transverse cervical and transverse scapular arteries and the subclavian vein. To the medial side of the muscle lies the carotid sheath, and the brachial plexes is on the lateral side.

The accessary roots of the phrenic nerve may join the main stem either in the neck or below the subclavian vein in the mediastinum. It has been demonstrated that none of the accessary roots join the main stem at a distance of more than 10 to 12 c. m. below the level of the clavicle, so that when 12 c. m. of the nerve is removed it can safely be assumed that all paths of transmission have been interrupted.

In determining the site of operation two factors should be considered—the site at which the main stem of the phrenic is most accessable and the site at which the accessary roots are most accessable. Since paralysis of one half of the diaphragm depends upon interrupting the fibers of not only the main stem, but all contributory fibers as well, which procedure is termed "Radical Phrenic Exairesis," and since the phrenic is without anomalies or accessary roots in only 35 per cent, it would seem that the site where the accessary fibers are most easily reached would be This would place the incision the proper one. low in the neck, below the omo-hyoid and just above the clavicle, whereas the main stem alone

is most easily approached at a higher level above

the omo-hyoid. The vertical incision leaves more scar than the horizontal which can be made in one of the nor-

mal creases of the skin. For reasons above stated the incision is made approximately 2 e. m. above the claviele, in a

horizontal direction. It begins over the lateral border of the clavicular head of the sterno-mastoid muscle and extends laterally for 2 or 3 c. m. and ends medial to the external jugular vein. If this vein is nearer the sterno-mastoid muscle than usual, the incision may be carried mesially over the lateral border of the sterno-mastoid muscle as there is no necessity for dividing the external jugular vein. The incision is carried through the skin, superficial fascia and platysma to the deep cervical fascia. This fascia is easily recognized as it is dull, thick and yellowish grey in color. Using blunt dissection from this point on, the fascia is incised, exposing the underlying "fat pad."

If the omo-hyoid muscle lies near the clavicle it will be in the field of operation and should be retracted upward.

Passing through the "fat pad" are the transverse cervical, and sometimes the superficial cervical arteries which may give troublesome bleeding if care is not taken in retracting them.

At a slightly lower level somewhat under the clavicle lies the transverse scapular artery.

The thin covering of this "fat pad" is opened and the fat is retracted from the operative field. This exposes the thin prevertebral fascia covering the scalenus anticus and medius muscles, the brachial plexus and phrenic nerve.

The advice frequently seen in the current literature to insert the finger at this stage of the operation and identify the round belly of the scalenus anticus, is misleading as this muscle is very frequently flat and it is sometimes impossible to differentiate by touch alone between the scalenus anticus and medius. The identification

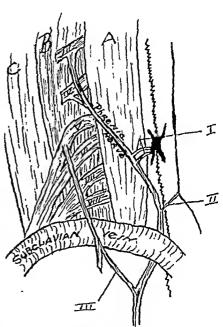

FIGURE 4

of the scalenus anticus is quite easy if one remembers that the earotid sheath bounds its medial aide and the brachial plexus its lateral side.

Due to the extreme mobility of the tissues of the neck a very wide area may be brought into sight through a small incision by retracting the tissues in varying directions.

Whenever possible the phrenic nerve is found before dividing the prevertebral fascia as otherwise it may be retracted from the field of operation along with the edges of the fascia. It can usually be seen as a white cord beneath the thin fascial covering. Having located the main stem, the fascia is divided and a search for accessary roots is made. The most constant accessary, from the nerve to thhe subclavius which in turn is from the fifth cervical nerve, lies to the lateral side of the main stem. As this accessary may join the phrenic below the level of the clavicle, it is better to divide the nerve to the subclavius even though no accessary fibers are apparent. Roots from the cervical nerves, the hypoglossal and the cervical sympathetic lie to the medial side of the phrenic and should be divided as close to the main stem as possible.

The main stem is then cut high up and the distal end is slowly pulled upwards, by wrapping it around the forceps or re-applying the forceps at a distance of 1 to 2 c. m. If traction is applied slowly and easily the entire length of the phrenic, with its diaphram filaments may be removed. There is a distinct thud when the nerve separates from its attachments. Even when pericardial or mediastinal adhesions exist, more than 12 c. m. of nerve can be avulsed. The traction is somewhat painful but should not be hurried. The cardiac impulse may be felt while applying traction on the nerve if mediastinal adhesions are present. The

respiratory tug may also be felt.

The act of injecting a drop of novocain into the phrenic nerve before it is cut is superfluous, as the phrenic is essentially a motor nerve and can be pinched or cut without pain. The pain is caused by traction and this traction is transmitted

beyond the anesthetized spot.

The greatest danger in phrenic avulsion is damage to the subclavian vein. This is a result of accessary fibers, particularly from the nerve to the subclavius, passing in front of the subclavian vein and joining the main stem of the phrenic which passes behind, thus forming a loop around the vein. If the accessary fibers are divided before traction is applied to the phrenic, the loop being broken no damage occurs to the subclavian vein.

After traction is applied any remaining accessary fibers may be severed as they appear in the incision. This danger applies not only to the subclavian vein, but to the transverse scapular

artery and the thoracic duct as well.

When it is also desired to sever the scalenae muscles this can be done at the same time and the steps of the operation are identical up to this point, with the exception of the incision which is carried laterally 2 or 3 additional centimeters. The external jugular vein is dissected and retracted. The scalenae muscles are exposed, elevated and severed near their attachments.

The scalenus anticus muscle must be severed below the level of the sixth cervical vertebra as part of its origin is from the transverse process of this vertebra. In this region its medial border is in relation with the carotid sheath, the thyrocervical artery and its branches. It is crossed by the transverse cervical and transverse scapular arteries, the phrenic nerve and the subclavian vein anteriorly. To its lateral border on the roots of the brachial plexus and posteriorly it is in relation with the dome of the pleura and the subclavian artery with its costo-cervical branch. Extreme caution must be taken in cutting this muscle, not to wound the pleura or subclavian artery posteriorly.

The scalenus medius is a more powerful muscle than the anticus. It is crossed anteriorly by the subclavian artery and the brachial plexus which separates this muscle from the anticus. The brachial plexus can be retracted outward or downward and the muscle severed, taking care not to wound the pleura.

The scalenus posticus is the smallest of the three muscles and lies posterior and lateral to the scalenus medius. It can be severed at the same level as the medius. Following scalenotomy the first and second ribs have a tendency to sag and the first rib drops away from the subclavian vein and artery. For this reason when scalenotomy has been done as a preliminary to thoracoplasty a much greater length of the first rib can be removed.

The operation is performed under infilteration anesthesia using 10 to 15 c. c. of a .5 per cent novocain solution.

MEDICAL RELIEF

Grave deficits in the administration of the relief provisions of the Public Welfare Law were shown on September 13 during the conference of secretaries of the county medical societies of New York State reported on page 1120 of this Journal It was also demonstrated that the defects can be corrected if a committee

of each county medical society will sit down with the welfare officials and discuss with their the problems of medical relief in that particular community The success of those county societies which have already acted is a challenge to all other societies to develop similar agreements with their welfare officers

THE NATIONAL RECOVERY ADMINISTRATION

A great parade in New York City—the largest in its history—took place on the afternoon of Wednesday, September 13, 1933, for the promotion of the program of the National Recovery Administration. Section 70 of the parade was assigned to physicians, with Dr. D. J. Kaliski as marshal. This recognition of the medical profession leads to a consideration of the place of physicians in the administration of the National Industrial Recovery Act.

The N.R.A. is concerned primarily with industrial and business conditions. It deals with the production and distribution of goods and wares whose value is material in distinction from those whose appeal is cultural and educational, such as art, literature, and music. The forms of industrial organization with which the N.R.A. is especially designed to deal are those in which the methods of mass production are followed, particularly those in which great capital is involved, and a large number of laborers are employed.

The physician does not come directly under the N.R.A., for he cannot be classed either as a capitalist, or as an employer of labor, or as a hired workman. He constitutes only one-tenth of one per cent of the people of the United States, and yet he is universally recognized as a most essential factor in every community, for it is he only who understands the inner workings of the human machinery and can keep it in good working order. His methods are in contrast with those of mass production, for each patient whom he serves is a thinking personality who expects individual attention from the doctor of his own choosing. The doctor's hours of labor are determined by the needs of the sick and the afflicted, and his remuneration is largely in accordance with the financial ability of his patient. His methods are not those of the factory or counting house, but rather of the educator and the ministering angel. To measure him by the standards of trade and industry is to do him an injustice. Yet he wishes to conform to the highest standards of conduct in his dealings with his fellow men and to give his hearty support to the principles of the N.R.A.

The essential feature of the N.R.A. is the code which defines the relations of employers to one another, and to those whom they employ. Representatives of each branch of industry were asked to propose a code defining the standards of action to which those engaged in the industry should conform. Approximately one thousand groups of industries have submitted their codes to the Federal Administrators. The voluntary formation of these codes, representing every kind

of business and industry, is a guarantee of their fairness, and insures their universal observance.

If physicians were required to formulate a code, they could show the oldest one governing any industry or profession. A code devised by the "Father of Medicine," Hippocrates, over 2,000 years ago, had been observed through the centuries until the present generation; and in an elaborated form it is still recognized as the rule and guide of faith and practice by the members of the Medical Society of the State of New York and the American Medical Association. If the N.R.A. does for industry what the doctor's code has done for medicine, it will abundantly justify itself.

A feature of every industrial code is the recognition of the right of the employed to act as a unit in entering into agreements with their employers regarding wages, hours of work and other essential conditions of labor. The object of the agreements is to give every workman a sufficient wage to enable him to obtain the necessities of life in such abundance and of such quality that he and his family can live according to the standards of modern society and without giving offence to his neighbor. Philosophers and economists could not foresee the anomaly of the last few years when men suffer dire want in the midst of plenty; when crops are too large to be utilized, and storehouses are bursting with goods; and when the Federal Government advocates the destruction of agricultural products as a means of improving the finances of the farmer.

Distress and want are largely man-made, and are curable by human effort. The people of the United States recognize their duty to provide the necessities of life for those who are temporarily unable to obtain them. These necessities are food, clothing and shelter; to which health has been added in recent years.

Health is not a commodity which can be bought and sold, or stored for future use. Its impairment usually comes unexpectedly, and the demand for its restoration is immediate and insistent. The doctor cannot control his hours of labor, nor hire others to do his work; yet he is in sympathy with the fundamental principles of the N.R.A., and will work unselfishly to give to others the health and vigor which will enable them to become self-reliant and independent.

The formal attitude of the medical profession toward the N.R.A. is well set forth in an editorial from the Journal of the American Medical Association which is reprinted on page 1118 of this Journal.

MEDICAL PROGRESS

Virus Obtained from Influenza Patients .--During the epidemic of influenza at the beginning of 1933 Wilson Smith, C. H. Andrewes and P. P. Laidlaw made experimental studies with the filtrates of throat washings, the results of which they embody in this preliminary report. The filtrates, proved to be bacteriologically sterile, were used in attempts to infect many different species. All such attempts were entirely unsuccessful until the ferret was used, when a disease was produced showing the characteristics of influenza in man. The disease was transmissible serially in ferrets either by contact or by the intranasal instillation of virus-containing material. The infective agent has, so far, been recovered only from the nasal passages of sick ferrets. The disease was produced by five of eight throat-washings obtained from influenza patients in the early stages of the disease. Throat washings from healthy persons and influenza convalescents caused no illness in the ferrets. The nasal secretions from a subject with a severe common cold caused no illness in ferrets. Human sera, particularly those from influenza convalescents, were found to contain antibodies capable of neutralizing the virus of the ferret disease. Swine influenza caused a disease in ferrets which was indistinguishable from that produced by the virus of human origin, and the pig and human viruses have close antigenic rela-The authors consider that the evidence submitted suggests that there is a virus element in epidemic influenza and that this virus is of great importance in the etiology of the hu-man disease. Their results are consistent with the view that epidemic influenza in man is primarily caused by a virus infection. It is probable that in certain cases this infection facilitates the invasion of the body by visible bacteria giving rise to various complications. Analogous examples of this type of double infection are seen in swine influenza and dog distemper epizoötics. Decisive evidence on this point, and indeed on the importance of the virus here described, can only be secured by intensive study during an influenza epidemic, since direct experiments on man are fraught with difficulties.-The Lancet, July 8, 1933, ccxxv, 5732.

Peripheral Vasoconstriction by Tobacco and Its Relation to Thrombo-Angiitis Obliterans.—In view of the very definite opinions that have been expressed concerning tobacco as a predisposing cause of thrombo-angiitis obliterans, Walter G. Maddock and Frederick A. Coller made a study of the vasoconstrictor action of tobacco smoking in man by means of skin temperature changes. The subjects

were young adult males and patients with thrombo-augiitis. The tobacco was smoked in the form of cigarettes. The investigation demonstrated a consistent increase in blood pressure and pulse rate and a decrease in the skin temperature of the fingers and toes. Control experiments gave definite evidence that these effects were due to active products absorbed from the tobacco smoke. Nicotine administered intravenously in quantities not greater than those absorbed in the smoking of one or two cigarettes produced comparatively analogous changes. More marked effects were noted when the subject "inhaled" while smoking rather than merely "puffing," and also with rapid smoking more than with slow smoking. The decrease in the peripheral skin temperature on smoking must be due to increased vasoconstriction. In a previous article the authors pointed out the value of measurements of the skin temperature of the fingers and toes under well controlled conditions as indication of stimulation or depression of the sympathetic nervous system. By increasing vasoconstriction smoking reduced the blood supply of the fingers and toes. With several subjects the reduction lasted more than thirty minutes from the time of cessation of smoking and generally was of longer duration in the toes than in the fingers. In the cases of thrombo-angiitis obliterans smoking produced the same eardiovascular response as in the normal subjects. The authors do not offer the results of this investigation as evidence that tobacco smoking is the sole etiological factor in thrombo-angiitis obliterans. The occurrence of the disease in individuals who have never smoked precludes that opinion. It is interesting, however, to recall that other vasoconstrictor substances, pituitrin and ergot, have been responsible for peripheral vascular occlusions and gangrene. There is no doubt that prolonged or marked vasoconstriction may initiate organic vascular occlusions. The experimental data presented form a rational basis for the clinical conclusions as to the deleterious influence of tobacco smoking on the progress of thrombo-angiitis obliterans. Its use definitely decreases the already deficient circulation in the extremities of individuals with that disease .- Annals of Surgery. July, 1933, xeviii, 1.

The Three Reflexogenous Zones and the Regulation of the Cardiovascular Tonus in the Erect Posture.—Physiology shows, according to D. Danielopolu and A. Aslan, that although the cardiac rlythm is more rapid in the wart.

cal than in the horizontal posture, the vertical posture exerts a reflex influence resulting in modifications of blood pressure which, together with the accelerated rhythm, has the effect of compensating the displacement of the blood mass of the upper half of the body into the lower half, thus assuring good cerebral circulation in the erect posture. These authors believe that the cardiovascular tonus is the result of the reciprocal action of a direct humoral factor and a reflex factor, the first engendering the second, and the second modifying the first. The direct tonus arises from the action of the humoral milieu exerted upon the sympathetic and parasympathetic cardiovascular nerve terminals and upon the centers; it is controlled and coordinated by the reflexogenous tissue zone. This direct humoral tonus is amphotropic in its effect upon the blood circulation, but with sympathetic predominance. The reflex tonus, on the other hand, is represented by two other reflexogenous zones, the cardio-aortic and the sinocarotid; it is amphotropic with parasympathetic predominance. It modifies the direct tonus by acting upon the cardiovascular centers and the centers of the organs that regulate the humoral milieu, thus diminishing the sympathetic predominance of the latter. Contrary to the conception of Hering, the authors have demonstrated that orthostatic tachycardia is produced even after paralysis of the parasympathetic by large doses of atropine, thus proving that it is due in great part to excitation of the sympathetic. The observation that there is no retardation of the heart rhythm in the recumbent position when the parasympathetic is completely paralyzed proves that the slowing down is due to excitation of reflexogenous zones by the blood mass, which passes suddenly from the lower to the upper half of the body, provoking by way of the reflexogenous zones an amphotropic reflex with parasympathetic predominance. Accordingly, if under normal conditions there is no cerebral anemia despite the displacement of blood into the lower part of the body in the erect posture, this is because the effects of such displacement are compensated by a pressor reflex due to excitation of the reflexogenous tissue zone of the lower half of the body, and by a diminution of the depressor tonus of the circulatory reflexogenous zones, phenomena which tend to raise the blood pressure and accelerate the heart rhythm. In weak or cachectic subjects, however, with vagotonic or hyposympathetic constitutions, a fall of blood pressure greater than normal occurs in the upper half of the body, accompanied by a well defined tachycardia, and sometimes with vertigo or even syncope upon standing erect. In such subjects the pressor reflex of tissue origin is exerted\ in less degree upon the

markedly hypotonic vessels, so that the pressure is not sufficiently equilibrated in the upper half of the body.—Bulletin de l'Académie de Médecine, June 6, 1933.

Dyspnoneurosis. The Importance of the Central Factor in the Physiopathogenesis of Dyspnea.—In addition to dyspneas of pulmonary, cardiac or mixed pathogenesis, says Guido Lami, in the Riforma medica of June 3, 1933, there is an important group consisting of cerebral or "central" dyspneas, caused by anatomopathologic changes or even by purely functional modifications of the nervous, cortical, subcortical and, especially, the bulbar and medullary centers which provide the nervous regulation of respiration. The most typical form is dyspnoneurosis, often, though not always, accompanied by manifestations of hysteria. The attacks, often quite painful for the subject, are as a rule accompanied by perfectly normal organic findings. In a case cited a healthy youth 16 years of age had for 2 weeks attacks of hyperventilation with dyspnea that came once or twice a day and lasted half an hour. Respiration rose to 28-30 per minute, and spirometric examination revealed a respiratory volume of 1000-1100 c.c., the equivalent of 30 liters per minute, and effective consumption of 340 c.c. oxygen in that Between the attacks respiration was normal, and there was no ground for affirming a neurovegetative dystonia. Following a combined treatment by neurotonics and suggestion the attacks disappeared. In every case of dyspnea an organic nucleus is to be presupposed, in which humoral, pulmonary and cardiac factors meet; but it must never be forgotten that to these there are constantly added, in varying proportion according to the individual case, neuropsychic factors that play the leading These cortical impulses, the intensity of which depends on the conditions of the profound somatic-psychic personality, and which, through the subcortical zones that regulate respiration, are transmitted to the bulbar centers and to the nuclei of the anterior cornua, condition on the one hand the degree of dyspneic sensibility and on the other the intensity of the contribution-always in evidence-made by the will to the respiration that has already been increased by the presence of humoral, pulmonary or cardiac factors. The degree of dyspneic sensibility represents the threshold beyond which the respiratory function ceases to be perfectly unconscious and involuntary and becomes conscious and painful, undergoing voluntary intensification through the inevitable superaddition of corfical impulses. This threshold varies with the individual and depends on factors that cannot be defined in an absolute sense. Thus a given pathologic condition that is practically identical in various patients will produce in some an intense dyspnea due to neuropsychie factors, and in others none at all unless the respiration is greatly increased beyond the normal, with marked reduction of the respiratory reserve. Emotional hyperventilation increasing the metabolism is often observed in dystonic individuals. This condition, frequently met in hyperthyroid constitutions, is often accompanied by sensations of dyspnea and as a rule by extreme instability of respiratory exchange.

The Management of the Newly Born .-Dame Louise McIlroy, writing in the Practitioner, July, 1933, exxxi, 781, calls attention to the fact that the highest mortality among infants is within the first twenty-four hours of life, and that the treatment of the newhorn leaves much to be desired. Careful antenatal supervision will to a great extent diminish the risks of labor and birth not only for the mother but for the child as well. the surroundings of the new-born should, as nearly as possible, be made to resemble the intrauterine conditions. The infant should be kept at rest in a warm atmosphere. It is most important that the mucus or amniotic fluid in the child's month should be prevented from entering the air passages when it takes its first breath. As soon as the child's mouth passes over the perineum it should be wiped out with a piece of gauze spread over the finger. The child should be wrapped in a warm blanket and laid between the mother's thighs until the cord is severed. The infant, after a rest, should be rubbed with warm olive oil, and when thus cleansed should be dressed. The skin is oiled daily until the stump of the cord falls off, when a soap and water bath can be given. The loss of heat results in more loss of weight, in the first few days after birth, in the bathed babies than in those who are oiled. In the treatment of asphyxia of the newly born methods such as that of Schultze should be looked upon as barbarous. When the baby is born in a state of blue asphyxia, it may be sufficient to wipe out its mouth or to suck out the mucus with a catheter. If not gentle massage of the chest will as a rule bring about the establishment of respiration. If the condition is that of white asphyxia it is useless to induce respiratory movements until the eardiac function is restored. After all mucus has been removed from the mouth and pharynx, carbon dioxide (5 per cent.) and oxygen (95 per cent.) should be given by means of a mask attached to a pressure gauge and a eylinder. Lobelin given in a 0.5 c.c. ampule is of value in helping to establish respiration in the newborn. Gentle tongue traction may be of value in some cases. Heart massage is also of use in stimulating cardiac function. Baths must not be given in cases of white asphyxia. Mouth

to mouth insufflation in the new-born infant is dangerous. If atelectasis is present after respiration has been partially established, the infant should be given oxygen at intervals. In the care of premature infants, the use of claborate glass cubicles may possibly lead to want of resistance when the child is removed from the hospital. A simple and satisfactory method is to use an ordinary cot with an awning placed partly over it by means of a metal Under the mattress are placed protected hot water bottles, and an electric bulb is suspended under the cage to warm the air. In the feeding of the newly born there is little to be said in favor of any method except that from the mother herself. Failing her, a wet nurse is the best substitute.

Asthma of Childhood.—Writing in the Bulletin de l'Académic de Médecine, of June 20, 1933, A. Haibe discusses the spasmodic asthma of children between the ages of 5 and 15, which is engrafted upon sequels of respiratory infections, especially of the rhino-bronchial apparatus, which create the inflammatory condition serving as the respiratory irritant. Two factors are always present: a general one, constituted by the humoral and vagosympathetic disequilibrium, and a local one, represented by the inflammatory irritant. The general factor, the "soil," is indispensable, but is not sufficient in itself to account for the attack, for which there must be a point of application, a zone of diminished resistance. Analysis of the secretions will reveal the progress of the infec-Bacterial examination of the secretions of the nose, throat and bronchi of several hundred asthmatic children has frequently revealed the presence of Staphylococcus in the nasal mucosa and of Streptococcus hæmolyticus in the bronchi. That these two microorganisms play the essential role in the etiology is proved by the results of vaccine therapy. In its early stages at least the asthma has all the characteristics of a reflex condi-The inflammatory process irritates the nerve terminations and, by the centripetal route, the pneumobulbar center. The centrifugal are of the reflex then makes use of the phrenic nerves to tetanize the diaphragm, of the motor fibers of the vagus provoke tlie bronchospasm and contracture of the inspiratory muscles. When the irritative process is in the nasal stage its route of transmission is that of the trigeminus; when in the bronchial stage, it is the sensory fibers of the pneumogastric. Treatment consists in the application of the appropriate antivirus and vaccine. When it is applied early enough, it hardly ever fails to cure. The attack is cut short, and the asthma does not return if eare is taken to persevere until results are consolidated. In inveterate cases treatment

should be repeated annually until allergy is transformed into immunity. One is readily convinced of the efficacy of the method when the results are observed. The coryza fails to reappear, or yields promptly to the antivirus; the bronchitis is cured and is not reactivated by the descending rhinitis; the crises of dyspnea are overcome or become progressively attenuated. The cure of the asthma of these older children may well be called the triumph of bacteriotherapy.

The Familial Occurrence of Ulcus Ventriculi. - Modern assertions that there is a familial tendency to peptic ulcer led A. Ritter and H. Keller to make a special study of the subject on a material of 378 operative cases recorded during a 10 year period at the University Clinic in Zurich and the Neumunster Hospital. The results of their investigations do not confirm those of other recent writers. In five cases in which a familial frequency was evident, they consider that special circumstances were present to account for the phenomena. An inherited anlage may be accepted as probable in Case 3, where three brothers, one sister, and three persons of the preceding generation had all suffered with gastric ulcer, and in Case 4, in which the patient, his mother, his brother, sister, and daughter had exhibited the same gastric affection. Case 5 was also significant, in which nine persons in three generations of a single family had been similarly affected. In these three families there is every indication that constitutionally weak stomachs were present; the cases seem to confirm Bauer's conception of a constitutional inferiority of a given organ, transmissible to offspring. All five cases support Bergmann's theory of the neurogenous origin of peptic ulcer, and Strauss's concept of a vegetative-neurotic disposition, since in every one there existed what that author termed "vegetative neuro-dysergia." In two of the families the presence of malignant new growths could be determined. In three of the families hyperchlorhydria was found, but with no marked conformity to any given type. Here and there the same localization could be asserted in two members of a family, but no general rule of this kind could be established. As a result of their investigations the authors conclude that the majority of peptic ulcers are unrelated to any familial predisposition. On the basis of their own verified postmortem material they do not hesitate to assert that constitution and heredity play no important part in the development of gastric ulcer, and that these constitute at most only a relative factor, entirely subordinate to other more important etiological factors. — Schweizerische medizinische Wochenschrift, June 10, 1933.

Practical Points in Otology of Special Interest to Pediatrists and General Internists.-William Hewson emphasizes the fact that ear conditions so often explain unexpected temperatures, intestinal upsets, and symptoms referable to the nervous, respiratory and other systems of the body that the examination of a child is no longer considered complete without careful scrutiny of the ears. A boy, 13 years old, was brought to him for a cough which had lasted for three weeks, since his return from the seashore. The examination of the nose, throat and ears was negative, except that a good-sized grain of sand was found in the little cul de sac in the vestibule of his right ear. After this was removed the cough stopped like magic. This cul de sac is likely to be missed if one uses an otoscope or a Hewson advises the more frequent use of a head mirror with reflected light. Impacted wax is best removed by the use of a small syringe with a fine gauge tip. This permits greater force for drilling through the wax. If the stream of water is directed to the margin of the wax, it will separate more quickly and is more likely to come away in one piece. It is rarely necessary to use olive oil, peroxide or bicarbonate of soda to soften the wax in children's ears if this method is followed. Local treatment of an external otitis must be directed only to the affected area or else extension and complications are apt to follow. Douching or much manipulation of the ear is contraindicated. Careful application of iodine, biniodide of mercury or yellow oxide of mercury and cold or hot packs are all that should be used locally. The general resistance may be raised by staphylococcus varcine and other general measures. Colds must be thought of in terms of acute otitis media and vice versa. Early in acute otitis media the disease is confined to the throat and treatment should be directed to the nose and throat. A little local treatment applied to the posterior nares and the orifices of the eustachian tubes can be easily accomplished and benefits the whole ear. Gentle shrinking followed by aspiration and bland oil have worked best in Hewson's experience. Reckless douching and spraying should be condemned. A child with acute nose and throat infection should be placed in the ventral position, as this favors drainage. It is well to remember that tonsils as well as adenoids may obstruct the eustachian tubes. In middle ear infection, after the drum has been incised, the danger of secondary infection should be taken into account, and every effort made to raise the patient's general resistance. After an acute middle ear infection has subsided local treatment should be employed to prevent the formation of adhesions which may lead to conductive deafness.— Laryngoscope, June, 1933, xliii, 6.

LEGAL

INSURANCE—SURGEON'S POLICY AGAINST ILLNESS AND ACCIDENTAL INJURY

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York,

Many physicians and surgeous carry large policies of insurance, taken with a view to protecting themselves against financial loss in their professional practice resulting from accidental injury or illness. Before such policy is taken out it is very important that the physician or surgeon should read his policy carefully so that he may be correctly informed as to exactly what is covered by the particular policy purchased. A case recently decided in one of our Federal Courts illustrates very well how a physician or surgeon may find that his policy does not cover his needs, although he may be confident that it does.

A doctor who was well-known as a surgeou not only in his own locality but as well abroad, had taken out a policy in the principal sum of \$50,000, which included what was called "Special Professional Coverage." The policy insured the doctor as a professional man "against dismemberment or complete and permanent loss of use of limb—resulting—trom (2) Disease of physical parts or members mentioned in Article 1 of this policy—." The clause in question provided that for complete and permanent loss of use of a right arm as a result of disease, seventy-five per cent of the capital amount of the policy would be paid to the assured.

While the policy was in effect the doctor was taken with an illness which resulted in paralysis agitans or palsy. The doctor had according to his testimony upon the trial devoted about ninety-five per cent of his work to surgery and had only practiced medicine as such in connection with his surgical practice. He had regularly performed more than one hundred major operations each year.

In applying for his policy of insurance he had filled in the form as follows with respect to his occupation:

4. Member of firm or employed by? B.... & O.... (North Chicago Hospital). In what business? General Hospital.

5. What is your occupation? Surgery and Physician. What are the duties of your occupation, fully described? Operating Surgeon.'

Subsequent to the illness his physical condition was such that it was a physical impossibility for him to participate actively in

any surgical operation. His right arm had developed a weakness, and his right hand shook continually. Occasionally he suffered brief spasms of the right arm. It was con-cededly a permanent condition. Such ordinary functions as tying a necktie, shaving, or raising liquids to the lips could not be accomplished with the right hand. He, however, with difficulty using the left hand together with the right, managed to make the right hand somewhat useful to pick up objects, to cut foods while eating and to write. The doctor after a period of convalescence resumed a portion of his practice under difficulties. He maintained his office and was repeatedly consulted by nationts for diagnosis. He managed to use a stethoscope and to test by percussion, tapping with the fingers of his right hand, however difficult a procedure. He continued to write prescriptions using the right hand, and succeeded to write out the names of medicines, and to sign his name. The doctor made certain bimanual examinations, but also under difficulties due to limited sensation in his right hand.

The insurance company refused to consider that the doctor was entitled to payment under the policy for the loss of the use of his right hand and arm, and he brought a suit in the Federal Court to recover the sum of \$37,500, the amount to which he claimed to be entitled under the policy. The case came on for trial and the plaintiff's evidence was put in, proving in substance the facts above set forth. The trial court at the close of the plaintiff's evidence directed a verdict in favor of the insurance company. From the judgment entered thereon an appeal was taken.

It was urged on appeal that with reference to his occupation as a surgeon the proof showed that the plaintiff had sustained a complete and permanent loss of use of his right hand or arm under the policy. He claimed to have been insured as an operating surgeon, and that for all practical purposes his arm and hand were completely and permanently lost to him for pursning the occupation for which he was insured. The Appellate Court, however, determined the appeal against the doctor and ruled that the record showed that

the plaintiff's arm and hand were of sufficient actual practical use to him in his occupation as to prevent the company from being liable on the clause in the accident insurance policy referred to above. The court found against the doctor. He had been insured as a physician and surgeon; and the fact that ninety-five percent of his work had been surgery was not made part of the insurance contract, or brought to the attention of the company when the policy was taken out.

In deciding in favor of the insurance company the Appellate Court said in part:

"Surgery is commonly defined as the art or practice of healing by manual operation. It is that branch of medical science which treats of mechanical or operative measures for healing diseases, deformities or injuries. It obviously presupposes a knowledge and practice of medicine as applied to surgical cases. It is fair to say from the evidence that it also contemplates examination, manual and otherwise, diagnosis, and preliminary and subsequent treatment. We assume that examinations, diagnosis and treatment in a strict sense are to be considered as the practice of medicine incident to surgery and not as surgery itself, but, be that as it may, all of these things were done by appellant in connection with his operative surgery at the time the policy was issued and they, together with operative surgery, were unquestionably covered by the policy.

"Appellant's testimony discloses that he is now and has been since his sickness, doing everything in the practice of his profession that he did before his sickness with the exception of using the knife in the operations, and in doing those things he uses his right hand and arm-not perhaps as well or with as much ease as he formerly did, but certainly in such manner and extent as to constitute some actual practical use of his right arm and hand in the pursuit of his profession. The use of a stethoscope, the act of percussion, the writing of prescriptions, the bimanual examination for adhesions as a result of abdominal operations, and for other purposes, are all matters in which the right hand and arm perform some actual practical function, and appellant testified that he does these things, although not with ease. As to whether appellant is able to administer surgical aid in cases where the knife is not used, such as the reduction of fractures, the record is silent. If he is able to do such things by the use of his right hand and arm, that, it seems to us, would be some actual practical use of his right arm in the pursuit of his profession as an operative surgeon; and it would defeat liability on the policy.

"There is no doubt that appellant has sustained a very great and serious loss in the use of his right arm and hand, and it is permanent. He has been deprived of that use which no doubt was dearer to him than any other part of his work, but that fact itself is not determinative of his right to recover in this action. This is not a suit for damages, but it is one to enforce a contract right, and we cannot enlarge upon the terms of the contract."

The decision may seem harsh. There can be no question that the surgeon in taking out the policy believed that he was protected against the very contingency which happened in this case, but the court was powerless to construe the policy otherwise than it did interpret it.

ALLEGED IMPROPER TREATMENT OF FRACTURE

A middle aged woman fell on an icy sidewalk, her weight falling on her outstretched hand. She immediately felt severe pain in her wrist and shortly thereafter reported to a local hospital where an x-ray was taken which report showed a fracture of the left radius in the lower third near the joint. There were two fracture lines; an irregular transverse line extending through the bone and a shorter horizontal line extending into the joint with slight impaction and posterior displacement of the distal fragments. A surgeon was called into the case for reduction and subsequent treatment. He put the woman under a gas oxygen anesthesia and reduced the deformity without a large amount of manipulation. The hand was readily flexed at a right angle to the wrist

and antero-posterior moulded plaster splints were applied extending to the metacarpo-phalangeal articulation and to the upper third of the radius and ulna. The splints were applied without constriction at any point, allowing room for subsequent swelling. The patient was allowed to go home after she came out of the anesthesia and was advised to report every day for dressing and to keep the arm continually elevated.

The next day the doctor saw the patient and rebandaged the arm as he found the splints had been slightly loosened. The condition at that time was satisfactory and he continued to see her almost daily for a period of several weeks. Six days following the reduction the anterior splint was removed entirely and the

posterior splint was shortened and straightened at that time. The hand had been flexed to a right angle on the forearm at the time of reduction and at this time was straightened to about ten degrees flexion. During the second week of treatment there was moderate swelling extending down into the fingers and the patient complained of inability to move the fingers or the thumb. The fragments however remained in good position. All splints were removed about four weeks after the injury. The patient, however, from that time on displayed marked unwillingness to attempt any movement of the wrist or hand. Careful instructions were given to the patient as to her exercise and she was referred to the psysiotherapy department of the hospital for baking and massage and the institution of mild passive motion. About seven weeks after the injury the patient reported to the doctor that she was still unable to use her fingers and hand due to pain. The doctor examined her and found that due to her lack of cooperation passive motion had not brought about anv satisfactory results. He therefore made arrangements to put her under anesthesia for the purpose of manipulation but the patient failed to report in accordance with the arrangements and never saw the doctor thereafter.

The patient brought a malpractice action against the doctor charging that by reason of his alleged negligence her hand was bent out of a straight and normal position and that the defendant allowed it to remain in that position so that a permanent deformity had resulted. She charged the doctor with improper application of the east and bandages to her wrist and arm and failure to properly remove or loosen the same at the proper times, and further charged him with improper manipulation and massage of the injured parts. The case was brought on for trial before a judge and jury and at the close of the plaintiff's case a motion was made on behalf of the defendant doctor to dismiss the case on the merits, on the ground that the plaintiff and her witnesses had not proved that the doctor in any manner had departed from proper and approved practice in his treatment of the case. The motion was granted and judgment entered in favor of the doctor, thereby successfully ending the matter.

BURN DISCOVERED SUBSEQUENT TO OPERATION

LEGAL

A specialist in surgery was consulted by a woman complaining of irregular menstruation and bleeding. He recommended that she enter a hospital for observation and there decided to perform upon her a diagnostic dilatation and curettage. The operation was performed and the laboratory report returned a diagnosis of chronic hypertrophic endometritis. The operation itself was uneventful and the woman came out of other anesthesia in an excellent condition.

When the doctor called to examine the patient the morning after the operation she complained to him of severe pains in the region of the lower spine. He examined her and found three large blisters over the eoecyx. He was unable to determine whether the burns were received by the patient moving on the operating table or whether they were hot water bottle or acid burns. They were classified by the doctor as second degree burns. She remained in the hospital for a few days and during that time the doctor treated the patient's blisters. At the time of her discharge from the hospital the burns were clearing up pretty well.

Some time thereafter a suit was instituted against the doctor to recover large damages, charging the doctor with negligently having moved the body of the plaintiff while the operation was being performed and while she was under an anesthesia in such a manner as to cause the skin of her back to be caught and injured by contact with the surface of the operating table or with certain articles thereon. The case came on for trial before a judge and jury; and plaintiff proved that she had sustained blisters but was unable to show that the blisters were connected with any negligent or improper treatment on the part of the defendant.

A motion was made to dismiss the complaint at the close of testimony introduced on behalf of the plaintiff and the court granted the motion. The doctor thereby was successful in the case without being put to his defense and without the issues of the case being submitted to the jury.

NEWS NOTES

PHYSICIANS AND THE NATIONAL RECOVERY ADMINISTRATION

The Journal of the American Medical Association for August 26, 1933, contains an editorial announcement of the relation of physicians to the National Industrial Recovery Act, quoting Mr. Donald R. Richberg, general counsel of the National Recovery Administration, as follows:

WE DO OUR PART

Fig. 1. Emblem to be displayed by employers of labor.

"Hospitals, not engaged in carrying on a trade or industry, do not come within the purview of the National Industrial Recovery Act, so as to come under the ordinary requirement of a code of fair competition.

"There is nothing to prevent any employer of labor outside of trades and industries, any professional man or organization, or any non-profit organization, from signing the President's Reemployment Agreement and conforming to its provisions. This does not mean, however, that they are under any compulsion to do so other than that resulting from a desire to cooperate where appropriate, and so far as possible, with a general program of reemployment at shorter hours and higher wages.

"To the extent that labor is employed in occupations comparable with those engaged in trade or industry, it is of course desirable that similar conditions should prevail."

The editorial continues, as follows, expressing the views of the A.M.A. leaders:

"Outside of the trades and industries, therefore, a hospital, a professional man or organization, and a non-profit organization of any kind are under no legal duty to formulate and adopt a code of fair practice or to sign the President's reemployment agreement. With them the adoption of codes and the signing of the agreement are matters of circumstance and of patriotism. Whether a physician will or will not sign the President's reemployment agreement and display the official emblem in his office, on his automobile and elsewhere may, of course, be determined by the local medical organization in each community."

WE DO OUR PART

Fig. 2. Emblem to be displayed by consumers, which means practically every self-supporting person not an employer of labor.

Unconscious Discrimination

The A.M.A. Journal brings up the points of unconscious discrimination and unfavorable reflection if a doctor displays the agreement, while his colleagues do not:

"Obviously, if a physician whose financial circumstances enable him without hardship to reduce the hours of his employees and to pay the wages specified in the President's reem-

ployment agreement signs the agreement and displays the emblem, indicating to the public that he has done so, he may work an injustice on his financially less fortunate fellow practitioners. He would, perhaps, leave the public in doubt as to whether their failure to display the emblem is due to lack of patriotism or to lack of professional or financial success. This conduct certainly would not constitute fair practice, which, after all, is one of the prime objectives of the National Industry Recovery Act."

The Consumer's Agreement

The editorial ends with the following advice concerning the Consumer's Agreement and Emblem

"If all physicians in a community cannot without induc hardship sign the President's recumployment agreement and conform to its exact terms as they are written, a local medical

society that desires to cooperate with the President without violating the principles of fair practice may follow either of two courses

"Under paragraph 14 of the President's reemployment agreement it may ask for a modification that will permit compliance without hardship, or

"It may advise its members to circll under the consumer's agreement and to display only the consumer's emblem."

The consumer's agreement which each individual is asked to sign is as follows

"I will ecoperate in reemployment by supporting and patronizing employers and workers who are members of NRA'

The official consumer's emblem is similar to that of the producer's or cuployer's, except that it bears the word "Consumer instead of 'Member' as shown in the copies supplied by the NRA headquarters

THIRD DISTRICT BRANCH MEETING

The Iwenty-seventh Annual Meeting of the Third District Branch of the Medical Society of the State of New York was held on Thesdry, September 5, 1933, at Haunes Falls, New York in the Catskill Mountain House on the brow of the mountain overlooking the broad valley toward Catskill The President, Dr Clark G Russman of Hudson, presided, and seventy members were present

The Third District Branch is composed of seven counties extending across the State southwest from Albany. The number of members in the constituent County Societies ou September 1, 1933, was Albany, 250, Columbia, 36, Greene 23, Rensselaer, 108, Schoharie, 20, Sullivan, 38, and Ulster 66, total 545

The meeting consisted of a business and scientific session in the morning, a noon lunch con with after dinner speaking, and an afternoon scientific session

The first number on the program was a County Presidents Round Table at which a representative of each county outlined the particular problems in his County Society and the manner in which the Society was trying to solve them

Dr R A Lawrence President of the Albany County Society, said that his society s greatest problem was the abuse of hospitals and dispensaries. Patients from outside of the county came to the Albany clinics for treatment when they were able to pay their own family doctors at home.

Another problem was the administration of toxin anti-toxin to school children, it being done principally by the Department of Health

free when it should be done by the family

ปฏิวัยเก๋านะ

Dr Louis Van Hoesen President of Columbia County Society, reported that his County Society was emphasizing the public relations of doctors to the community. While pamplilets were being distributed telling what a patient should know about tuberculosis and cancer, another our should be added on the subject "What everyone should know about his physician." Unscrippilons physicians had promised impossible cures and collected big fees in advance, thereby undermining the people's faith in doctors generally

Dr Van Hocsen said that when a baby born in Columbia County reaches the age of six months it is visited by the public health nurse and its parents urged to give it immunization against diphtheria. A further check-up is made three months afterwards

Dr L B Honeyford, President of Greene County Society, said that the County Board of Supervisors had chiminated the two public health nurses of the county on the ground of expense, thereby seriously crippling a great part of the public health work of the county the nurses had secured many diphtheria immunizations, but the doctors will continue to do the work on their own initiative

A public health worker from outside of the county had outlined a plan of an anti venereal campaign based on evaggerated statistics, but nothing further was done

Dr Honeyford said the County Hospital which had opened on August 10, 1933, now has thirty patients although twenty five is its

rated capacity; but he protested against the double burden which had been imposed on physicians in requiring them to treat the indigent in the hospital free, although the doctors already pay taxes for the support of the hospital on the same basis as other groups of citizens support it. Doctors are at the head of all groups in their contributions to charity.

Dr. G. F. Herben, President of Sullivan county Society, said that his Society was undertaking a survey of school children. Although the county public health nurse had been dropped, yet the County Society is making a major effort to carry on her work among the school children, and plans to offer a course on tuberculosis beginning on October 18th for the benefit of physicians.

Dr. F. M. Holcombe, President of Ulster County Society, said that a great problem in his County was to get officials to assume their proportion of the cost of giving medical service to the poor.

Dr. Frank Overton, Executive Editor of the New York State Journal of Medicine, responding to an invitation to discuss the reports, said that the record of the work done by the County Societies and the opinions given by the Presidents were of great value to physicians everywhere in the State, for all County Societies were considering the problems which had been mentioned. A record of the development of a piece of work by even a small society is a great value to all other societies. The New York State Journal of Medicine features the activities of all the County Medical Societies and District Branches from which it can get reports for the items of progress and development in the counties constitute the record of the State.

The scientific paper of the morning was given by Dr. Edward M. Livingston of New York City on "The Interpretation of Abdominal Signs and Symptoms; a Practical Study of Visceral Neurology." Dr. Livingston had conducted an extensive series of original investigations in Bellevue Hospital, New York City, on neurological signs and symptoms produced by irritation of various abdominal organs. The method was to irritate an organ-inflate a ureter for example,—and observe the pain, reflexes, tenderness, rigidity and other abnormal conditions that were produced. The correlation of the signs and symptoms of a patient with the anatomical distribution of the nerves gives reliable information regarding the location and extent of the abnormality.

Dr. Livingston showed lantern slides and moving pictures which demonstrated the newer methods of examination and observation which are now available to the bed-side observer. The illustrations were chosen from the doctor's new book, entitled "A Clinical Study of the Abdominal Cavity and Peretineum."

Two practical papers were presented at the afternoon session, as follows:

"Certain Forms of Increased Intracranial Pressure and their Treatment," by Dr. Gilbert Horrax.

"Some Varieties of Delayed Speech in Chil-

dren," by Dr. Samuel T. Orton.

The after-dinner speakers at the noon luncheon were Dr. Frederick H. Flaherty of Syracuse, President of the Medical Society of the State of New York; Dr. Arthur J. Bedell of Albany, President-Elect; and Dr. A. J. Hambrook, member of the Committee on Public Relations.

SECRETARIES' CONFERENCE

The annual conference of the secretaries of the component County Medical Societies of the Medical Society of the State of New York was held in the Hotel Ten Eyck, Albany, N. Y., on Wednesday, September 13, 1933, beginning 10 o'clock in the morning. Twenty-eight counties were represented as follows:

Albany, H. L. Nelms; Bronx, I. J. Landsman; Broome, G. S. Lape; Clinton, A. S. Schneider; Columbia, H. G. Galster; Cortland, O. E. White; Erie. L. W. Beamis; Essex, L. H. Gaus; Genesee, P. J. DiNatale: Greene, W. M. Rapp; Herkimer, W. B. Brooks; Jefferson, C. A. Prodhon; Kings, James Steele; Monroe, W. A. MacVay; Montales, T.; Charles, New York, Peter Irving; Hale, Jr.; Onondago, E. E. Mack; S. Roach; Otsego, F. J. Atwell; W. J. Ryan; St. Lawrence, S. W.

Sayer; Saratoga, H. L. Loop; Schoharie, H. L. Odell; Schuyler. F. C. Ward; Suffolk, F. Overton; Sullivan, L. C. Payne.

The following representatives of the Medical Society of the State of New York were present

and took part in the discussions:

Dr. Frederic Flaherty, President; Dr. S. J. Kopetzky, Speaker of the House of Delegates; Dr. Peter Irving, Assistant Secretary, who presided; Dr. J. N. Vander Veer, chairman of the special committee on Temporary Emergency Relief; Dr. J. S. Lawrence, Executive Officer; Dr. Frank Overton, Executive Editor.

The program of the conference was as follows:

1, '' Relief under Welfare Programs.

porary 1 of Ad-

C. Old Age Pension.

- 2. Hospital Dispensory Problems.
 - A. Rochester.
 - B. Buffalo.
 - C. Greater New York.

The discussion on all these subjects was led by Dr. J. S. Lawrence, who had made a special study of the Public Welfare Law which became effective on April 12, 1929, and of the manner of the administration of its medical provisions in the several counties. Dr. Lawrence had provided each representative with an official copy of the Law revised to July 1, 1933, and had prepared the following outline of the relation of the welfare officers to the physicians, as set forth in the Law:

I. Medical Care for the Indigent:

1. Each county has a welfare commissioner and each city and town has a welfare officer. (Pages 9 and 10.)

2. Commissioner must provide and with local funds pay for medical care for indigent, except for communicable diseases. (Pages 9, 25, and 26,)

3. He may use his judgment as to who shall furnish it and the amount. (Page 26.)

4. County commissioner is responsible for those who have no town residence or who apply from a town other than that in which they reside. (Pages 11 and 23.)

5. Many cities have charter provisions for salaried city physicians.

6. In a few counties the welfare officer has entire responsibility.

7. In most counties the town or city welfare officer provides home care, while county officer provides hospital service. (Pages 11 and 12.)

8. It is not demanded, but expected, that the

family physician, when there is one, shall be employed. When there is none, then a physician residing near to the patient is to be called. Page 25.)

9. The welfare officer may contract with a physi-

cian for the work. (Page 26.)

10. Physicians should not render service except in emergency (one call) without authorization from the responsible welfare officer. (Page 27.) 11. Bills should be presented promptly

12. Services and fees must be reasonable.

Temporary Emergency Relief Administration:
 The T.E.R.A. will refund to county, town and

- city welfare officers, according to an adopted schedule, 40% of all sums expended in home 2. Ordinarily it will not refund any portion of
- funds expended for hospitalization, mileage or salaries of contract physicians.
- III. Medical Care of Inmates of Public Homes. (Page

IV. Defective Children. (Page 33.)

- V. Children Born Out of Wedlock: (Pages 33 and 34.) 1. Care for such child with its mother.
 - 2. Provide for expert mental and physical exami-
 - nation.
 - 3. Provide medical and surgical care.

VI. Births in Public Homes: (Page 35.)

1. Provide suitable maintenance and medical care somewhere else, if the home is not properly equipped.

Provide Relief and Care of Veterans. (Page 37.) VIII. Old Age Relief. (Pages 43 and 44.)

The Administration of the Public Welfare Law has varied widely in the counties owing largely to the nature of the law itself. The law provides for a county welfare commissioner and for a continuance of local "Poor Officials" in the local towns, while many cities are under special charters. The county may be the unit of administration with the town officials as the deputies of the County Commissioner or, it may be by towns, with the county commissioner performing his duties as he did under the old law. Few of the counties have adopted the county system, and most townships are still independent units. There is, therefore, no uniformity in the method of supplying medical relief, and physicians are confused as to their duties and uncertain as to their pay.

There was a free recital of the difficulties under which physicians labor in giving medical relief under the Public Welfare Law; but it was agreed that the law was administered with a reasonable degree of satisfaction in those counties in which a committee of the County Medical Society had discussed their problems with the local welfare officials, and had entered into agreements with them regarding fees, methods of calling physicians, rendering bills, and other details. The conference adopted the following motion:

Resolved, That each county Medical Society be urged to have a committee which should confer with the county and town welfare officials and work out administrative methods adapted to that county.

The method of employing a physician to treat the poor on a contract basis was condemned, and the conference voted to favor the employment of the family doctor of the patient's own choice.

The conference also voted to approve the principle of giving medical care in the home so far as possible, rather than sending the patient to a hospital.

The afternoon session was devoted to a discussion of the subject of the abuse of free dispensary service. Dr. W. A. MacVey of Rochester told how the physicians and social service organizations of his city had cooperated in establishing a system of investigating all applicants for free relief in dispensaries.

Dr. L. W. Beamis described a similar system that has been adopted in Buffalo; and commented on its failures as well as its successes.

Dr. Peter Irving outlined some of the legal difficulties which prevent the correction of dispensary abuses in Greater New York especially the general principle that there can be no discrimination among the recipients of the benefits of public funds.

Dr. I. J. Landsman described a survey now being conducted by the Bronx County Medical Society of the financial status of every patient applying for relief at one of the large hospitals of Bronx Borough. The survey has already yielded

OUR NEIGHBORS

MEDICAL ETHICS IN MASSACHUSETTS

The New England Journal of Medicine of June 22 contains the presidential address of Dr. H. G. Stetson, before the Massachusetts Medical Society. Discussing the enforcement of medical ethics, Dr. Stetson says:

"In a recent study of the work of the Committee on Ethics and Discipline there is an element of interest, but not, I am sorry to say, one of pride in discovering that this Committee within the past five years has been called upon to investigate the conduct of 104 practitioners, members of this Society, who have been accused of conduct unbecoming a physician in one way or another. It is interesting to note that physicians who have been so investigated are not graduates of any one particular school, but so far as can be learned, all schools are represented without any particular disparagement to any one. Two conclusions came to me in the study of this report, which I feel are of enough importance to place before you.

"First, greater attention should be paid to the admission of candidates to our Society, by the Censors in the different districts. It is not always possible to exclude the undesirable, by this means, but a few cases show definitely that the physician who ultimately comes before the Committee on Ethics and Discipline should never have been admitted. The character of the work carried on since his admission to the Society was definitely shown by the same character previous to his admission, and should have been known to the Censors of the district. The mere fact that he has been able to pass the medical examination for admission to the Society constitutes, as I understand it, only 60 per cent of the requirements for

admission. The remaining 40 per cent applies to ethics, to his standing among his fellow practitioners, and in his more or less public relations in the community in which he lives. One hundred and four studies in the past five years is not large, but I believe that a more careful examination of the ethics and standing of the applicant previous to admission would lessen the number of our undesirable members.

"Secondly, a study of the work of this Committee, together with some evidence that has been produced in the Committee on Public Relations, would lead me to believe that insufficient attention is placed upon medical ethics and upon business No small economics in our medical schools. amount of the medical graduate's success in life depends upon his knowledge of business ethics and business principles and his relationships with his fellow practitioners, and I believe that more time could be devoted in our medical school courses looking toward a more complete understanding and knowledge of these two subjects. The physician is constantly being criticized by the business man for his lack of business knowledge and business principle, and while the practice of medicine is a profession, it should be governed, if we are to be successful in our contacts with others, by reasonable business judgment and business knowledge. The statement is made altogether too often by the younger practitioner when he begins the practice of his profession, that his knowledge of medical ethics is largely obtained after his graduation. The success of our profession depends, I believe, not upon more business but upon better business."

THE INDIGENT IN PENNSYLVANIA

The July number of the *Pennsylvania Medical Journal* contains the following proposal which the Chester County Medical Society will submit to the Board of Supervisors of the County. The circular letter of the secretary of the county society is as follows:

"The medical profession in Chester County is at present, and has for many years, given thousands of dollars of medical service annually to the indigent of Chester County. Our Committee on Economics feels that this is an unfair and unsound policy, for three major reasons:

"1. The indigent do not receive proper or adequate medical attention under such an arrange-

ment as has been so clearly shown by the Committee on the Costs of Medical Care.

"2. The physician is actually deprived of considerable income which he has properly earned and is rightfully entitled to.

"3. The county and hence the taxpayers expend thousands of dollars, caring for bedfast, indigent patients, when illness might have been prevented if proper medical attention had been granted years before.

"We feel that while charitable service will always characterize the profession of medicine, this excessive load for the strictly indigent prevents

of choice for thirty years mever advertised to the public

"The dextrin-maltose preparations possess certain advantages. When they are added to cow's milk mixtures, we have a combination of three forms of carbohydrates, lactose, dextrin and maltose, all having different reactions in the intestinal tract and different absorption rates. Because of the relatively slower conversion of dextrins to maltose and then to dextrose, fermentative processes are less likely to develop. Those preparations containing relatively more maltose are more laxative than those containing a higher percentage of dextrin (unless alkali salts such as potassium salts are added). It is common experience clinically that larger amounts of dextrin-maltose preparations may be fed as compared with the simple sugars. Obviously, when there is a lessened sugar tolerance such as occurs in many digestive disturbances, dextrin-maltose compounds may be used to advantage." (Queries and Minor Notes, J.A.M.A., 88:266)

POTENCY MEANS SMALLER DOSAGE

1 TABLET OF

PHILLIPS'
MILK OF MAGNESIA

I teaspoonful of liquid Phillips' Milk of Magnesia

I tablespoonful of saturated sodium bicarbonate solution

I glass of lime water

The ability of milk of magnesia to neutralize excess addity in the stomach has been established. For over 60 years Phillips' Milk of Magnesia has been a standard agent for use in gostric and intestinal disturbances.

Now you are able to give your patients an added service—milk of magnesia in tablet form. These tablets are concentrated, safe and pleasant to take. They may be carried about on the person and thus permit ambulant patients to take them periodically.

cally.

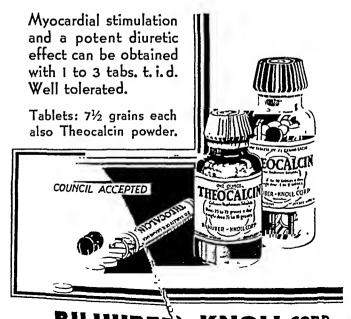

The same standard of quality for which Phillips' Milk of Magnesia has become famous is contained in these new tablets.

the profession from extending charity, that is undoubtedly deserved to even a larger class of people: those who are endeavoring to maintain their independent financial status despite great handicaps. The average general practitioner of medicine after possibly thirty years of service will leave a net estate of \$15,000; during that same time, he will have given in uncompensated service to the community an amount in excess of \$66,000. We feel that any effort looking toward a better distribution of the cost of medical care for the pay or part-pay patient should be based on the fact that those patients now unemployed and on 'relief' are properly a community charge not only for food, fuel, and shelter, but for essential

and emergency medical relief.

"The Committee on Economics of the Chester County Medical Society, therefore, propose to present its case definitely and concisely to our county commissioners. In brief, we propose to ask the county to appropriate to the Chester County Medical Society \$15,000, to be devoted to the care of patients who are now on the 'relief.' The procedure under the contract between our society and the county commissioners would be definitely specific. The members of our society would adopt a fee schedule for operations under this contract, a copy of the same being mailed to each member. All bills submitted to the society would conform to this fee schedule. Those patients on 'relief' after receiving from the Relief Committee of the county authorization for medical service, would then be treated by the physician of the patient's choice, namely, his family When the physician has completed his treatment of a patient on 'relief,' he mails to the proper agent of the society a statement of services rendered accompanied by the authorization slip. The medical men active under the terms of this agreement would furnish medical, surgical, and obstetric care on the basis of the fee schedule arranged. Our plan does not include hospital care, roentgen-ray photographs or treatments, antitoxins, serum, trusses, lenses, etc. The physician would furnish the ordinary office dressings and drugs. Our committee proposes that the society select one of its members, preferably the secretary, to act as the central agent for the society, whose duties would be to handle the correspondence, telephone messages, etc., connected with this work as well as to keep a record of the work done by the various physicians, using the bills received as a basis for this calculation. The Economics Committee, or perhaps an Auditing Committee appointed by the society, would meet at stated intervals to pass and decide upon any questions which might exist concerning any bills which had been rendered to the secretary. All expenses connected with the plan as well as the society dues of all the members would be deducted from the total sum received from the county. The (Continued on page 1128-adv. xiv)

Juture RESEARCH

Above: Sharp, short area prove that the mi-celles are oriented in regular, parallel array. Result: great tensile strength, definite digestion time.

Right: Diffuse, continuous rings prove that the sulure micelles are arranged nearly at random. Result: very poor strength, erralic and non-uniform degestion . . . ONLY X-RAY

diffraction technique can reveal these differences in catgut structure . . .

HEAT STERILIZED SUTURES

X.RAY is now rendering to medical science its third great service since 1895 . . . First came X.Ray diagnosis, then X.Ray therapy, and now X.Ray diffraction research with which the Curity Laboratories are now pioneering in the study of suture structure.

The practical properties of sutures depend ou the structural make-up of the catgut itself. Tremeodously small units in various arrangements determine what the characteristics of the catgut suture are going to be.

No microscope made is powerful ecough to see these units or to reveal this structure. Now, for the first time, Curity reveals catgut structure and studies its influence on suture teosile streogth and absorption by X-Ray diffraction.

With this new X-Ray technique, and other modern methods, the Curity Laboratories are conductiog research never hefore possible. Research that is bringing to light koowledge that coables Curity to produce sutures of greater tensile streagth, moore dependable absorption, grenter surgical snfety than ever before.

CURITY Sutures are heat sterilized and bacteriologieally tested by the Meleney and Chatfield technique.

There is nothing obligatory in this plan for any physician to treat a patient whom he does not care to treat or for an patient coming to a physician other than the on of his choice.

"Under the terms of the contract, the medical society, through its Committee on Medical Economics, merely proposes to provide a more intelligent arrangement for the care of those patient on county 'relief.' It is obvious that such a plai is only just and fair to the physicians, and we are equally confident that it will be a definite mark o progress in caring for the health of the people of the county."

LEGISLATION IN OKLAHOMA

The July issue of the Journal of the Okla homa State Medical Association has the following editorial on legislation affecting the practice of medicine in the State:

. "The last Legislature is to be congratulated on its very good common sense in taking the sensible and modern view of the various meas ures presented before it. Among its acts were

these:

"The prohibition or sale of marijuana, veronal, barbital, luminal, chloral hydrate, bromi dia or somnos except on the prescription of a licensed practitioner of medicine, osteopathy dentistry or veterinary medicine, which prevention would be almost the equivalent of requiring the purchaser to secure a prescription before buying a sack of common table salt o cooking soda.

"We question the practicability of this law It will at once place the drugs in the 'bootleg class, it will not prohibit the sale of a single

tablet.

"It refused to pass a legislative act permitting a poor, ignorant woman, far out in the western hills of the State, to follow her occupation of 'curing' cancer, by the application of certain compounds she alleged would cure the disease. In this case, too, we all know she has no cure for cancer but probably has a mixture

that is a hundred years or more old.

"It is left in the hands of the Governor as to whether the Post-Graduate Medical Extension work should be continued. Of course every physician in the State who studies these matters knows that this work is good not only for the physician but for the people at large, and should be continued. Its continuation, however, depends upon the amount of cash on or in sight, for, there are many other measures clamoring for continuation of appropriations, which lumped together amount to a consider-

MUCIN TREATMENT of Peptic Ulcer ... NOW CLINICALLY ESTABLISHED

THERE are numerous

chemical and dietetic treatments suggested for gastric and duodenal niceration, but none of them has a truly physiologic rationale. Gastric Mucin utilizes Nature's own measures for protection against irritation, thus permitting healing.

The Mucin method, which is physiologic in character, has been hinted at since Claude Bernard, but is now available for the first time in a practical form.

Starting with Fogelson's tests on a small group of patients in 1929, Gastrie Mucin has gradually developed into a safe and rational therapeutic measure.

A questionnaire report from physicians throughout the United States on over 500 cases showed the following results:

In 217 cases of intractable peptic ulcer not responding to any other therapy, 137 (63.1%) were rendered symptom-free; 64 (29.4%) improved; and 16 (7.5%) failed to respond. 69 of these cases had failed to respond to surgery.

seen that any physician would promptly refuse to make a call upon any such basis. The same physician, however, will make charity calls or tend the needs of the sick for nothing, if it is necessary, but to fix the amount at 25 cents per mile which one might charge for calling upon a well-to-do person, is pure folly. In the end the act would probably have been held unconstitutional by the State Supreme Court.

"It refused to pass an act permitting Osteopaths to enter a State- and County-owned hospital upon the same grounds as a finely qualified physician is permitted to enter them."

COUNCIL MEETINGS IN MASSACHUSETTS

Committee meetings of medical societies are likely to be so informal that some doctors become impatient, as did one member of the Council of the Massachusetts Medical Society, whose letter in the New England Journal of Medicine of June 29 was as follows:

"The terrific length of the last meeting of the Council and comments on the time consumed in considering petitions for the reinstatement of members lead me, a Councilor since 1902, to speak of certain possible improvements in man-

"Why can the meeting not start promptly at 12:00? It almost never begins before 12:15 or

even 12:20.

"Why must the Secretary read, even in abstract, the record of the previous meeting? It has already been printed and distributed. In most organizations this reading is on motion dispensed

"Should the presiding officer not familiarize himself before the meeting with the names of his

nominees for committee positions?

"At 3:30 P. M. I for the first time in my life went home before adjournment seeing no probable termination of a debate between two distinguished surgeons entirely uncontrolled by the chair.

"When adjournment was finally achieved I do not therefore personally know, but two and onehalf hours had already gone by with an extra hour

for luncheon and a camera interlude.

"Not one-half of those present before luncheon attended the afternoon meeting."

GRADUATE EDUCATION IN MASSACHUSETTS

The New England Journal of Medicine of May 28, 1933, contains the following editorial announcement of post-graduate courses which the Massachusetts Society offers to its members through its District Branches:

"County Societies desiring post-graduate instruction have only to apply to the Massachusetts Medical Society and they will be furnished a

(Continued on page 1131-adv. xvii)

(Continued from page 1130-adv. rri) course of ten exercises. These exercises will be given by a group of carefully selected teachers, and will be clinical in nature. District hospital facilities will be utilized for teaching centers as

far as possible.

"Post-graduate instruction has already been offered by State Societies in other parts of the country. The methods employed have varied in different localities, but on the whole have proved successful in bringing to doctors knowledge or viewpoints that are useful and stimulating. The Massachusetts Medical Society is to be congratulated on beginning this kind of work. The undertaking is a significant one which well may lead to important achievements."

The method of giving the courses is as follows:

"That an extension course consisting of a series of ten teaching lectures be made available.

'That a registration fee of \$5.00 be charged for a course of ten exercises.

"That instructors be paid expenses but no other

honorarium the first year.

"That a local chairman of post-graduate instruction be appointed in each district, this chairman to be nominated by the Executive Committee and approved by the District Society. The local chairman will have charge of the local registration, preparation of clinical material, attendance, etc.

That the courses be given two or three hours

per day.

"That exercises be given once per week or as

often as the District Society requests.

"That a list of subjects be published and sent to every District Society with the idea that they may choose any ten of the list."

The complete list of subjects names 22 topics, as follows:

"1. Practical Medical Principles for Everyday Use. (History taking, laboratory procedures, etc.)

"2. Vascular Disease.

"3. Gastro-Intestinal Disease.

Disease.

"4. Gastro-Intestinal Disease.

"5. Acute Infections.

"6. Diseases of the Blood and Hematopoietic System. "7. Praetical Psychiatric Problems.

"8. Medical and Surgical Emergencies. "9. Normal Pregnancy.

"19. Arthritis.

"20. Genito-Urinary Disease.

"21. Cancer.

"22. Dietary Problems in Certain Diseases."

WHEN THE DOCTOR'S ADVICE MEANS SO MUCH...

16,750,000 Children under 15 have, or have had, Rachitic Tendencies

30,000,000 have Dental Caries

There are 33,500,000 children in this country 14 years old or under. The American Medical Association estimates 50% to 75% base or hase bad rachitic tendenties, According to the White House Conference on Child Health and Protection, 95% (or over 30,000,000) of school children suffer from dental carres.

ALREADY in England the Ministry of Health is advising an adequate supply of vitamin-D. The Ministry points out that along with sufficient calcium and phosphorus, vitamin-D will prevent or cure rickets. It states further that both for the prevention and cure of rickets and to insure proper development of the teeth, the diet of pregnant and nursing mothers should contain all three of the ingredients mentioned. It asserts that vitamin-D is most apt to be deficient of these three. It states that the rate of progress of caries is decreased by additional vitamin-D in the diet. It advises all medical officers, especially at infant welfare centers, antenatal hospitals and during pregnancy, to secute an adequate supply of vitamin-D in the diet. For children especially it recommends more liberal use of milk.

Bond Bread is a rich source of vitamin-D, of special value to the public for these reasons: 1. The vitamin-D is free. 2. Bread is a natural part of every diet. 3. The amount of vitamin-D is uniform and scientifically controlled. In hospitals, for children, for mothers, prescribe this scarcest of vitamins (in natural foods) through Bond Bread.

PABLUM-MEAD'S PRE-COOKED CEREAL

Mead Johnson & Co. are now marketing Mead's Cereal in dried pre-cooked form, ready to serve, under the name of Pablum. This product combines all of the outstanding mineral and vitamin advantages of Mead's Cereal with great ease of preparation.

All the mother has to do to prepare Pablum is to measure the prescribed amount directly into the baby's cereal bowl and add previously boiled milk, water, or milk-and-water, stirring with a fork. It may be served hot or cold and for older children and adults, cream. salt and sugar may be added as desired.

Mothers will cooperate with physicians better in the feeding of their babies because Pablum is so easy to prepare. Please send for samples to Mead Johnson & Company, Evansville, Indiana.-Adv.

"CONGESTIVE HEART FAILURE"

Before the Cincinnati Heart Council, Dr. B. A. Schwartz reported on a series of 37 cases of congestive heart failure treated with digitalis and Metrazol (Ohio State Med. Jr. May 1933, page 308-310).

The author made use of the circulatory stimulant Metrazol in place of, or in conjunction with, digitalis in a selected group of 37 cases of chronic congestive heart failure in which digitalis did not prove effective or where the patient's gastro-intestinal or even nervous system was partially or wholly intolerant to this drug.

Case histories are given and many

cardiologists and a comprehensive bibliography is included.

In conclusion Dr. Schwartz writes: "Our clinical experience with digitalis and Metrazol in this group of cardiac patients with congestive failure, leads us to conclude that there is a definite synergistic relation between the two stimulants. In those cases where normal doses of digitalis had been found to be toxic or ineffective, smaller doses of this drug in conjunction with Metrazol often proved of value in obtaining the desired results. Where digitalis is not tolerated at all, Metrazol alone has been used references made to reports from with success. In cases of acute digi-

talis poisoning Metrazol has proved of definite value. In acute cardiovascular collapse the use of Metrazol is especially beneficial.

Information and a trial quantity of this circulatory and respiratory stimulant, Metrazol (Council Accepted) may be obtained, upon request to the manufacturers, Billiuber-Knoll Corp., 154 Ogden Ave., Jersey City, N. J.

FROM A LILLY BULLETIN

"The benefits derived from the use of local medicinal agents commonly prescribed in nasal therapy would appear to depend to a considerable extent upon the manner in which they are applied. Some physicians recommend the use of sprays, while others favor drops. Linn has called attention to the value of double spraying; the first shrinks the exterior turbinate, allowing the second spraying to reach more readily the important middle turbinate area. According to Jackson and Coates, gravity will carry further into the recesses of the nose and sinuses than a spray or applicator. In applying drops by the gravity, or postural, method, the patient lies on a couch or table with the head well down over the end. The drops, usually about ten, are instilled into each nostril. The head is then rolled from side to side. After two or three minutes a normal recumbent position is resumed and should be maintained for from three to five minutes. During this procedure the patient is instructed to breathe through the mouth and not to 'sniff.' Gentle tapping over the forehead may facilitate the spread and penetration of the drops."—Adv..

DISORDERS OF MUSCLE TONE AND THEIR LOCALIZING SIGNIFICANCE

By WALTER FREEMAN, MD, ST. CLIZABETH'S HOSPITAL, WASHINGTON, D C.

From the Department of Neurology, George Washington University Rend at the Annual Meeting of the Medical Society of the State of New York, at New York City, on April 5, 1933

THE recent discussions of muscle tonus and its various components have led to so much confusion that at a recent meeting Fulton decried the use of the word, saying that it had ceased to mean anything specific and should there-fore be discarded. To do so, however, would force us to fall back upon other terms whose definitions are equally unsatisfactory, and would deprive us of a term that everybody finds useful For purposes of present discussion, muscle tone may be defined as that quality of resistance met with upon passive movement of the segments of a limb Deviations from the normal may be both quantitative and qualitative. I propose to discuss some of these as a means of localizing lesions in the nervous system It goes without saying that muscle tone of itself is by no means sufficient for localization Hypotonius, for instance, may result from lesions as far up as the cerebral cortex, and hypertonus often results from spinal lesions Qualitative differences are often the important distinguishing features

In addition to "muscle touc" certain other terms frequently used in similar connectious may also be defined Spasticity is to be understood, for purposes of this paper, as the condition in which, with or without hypertonias, there is exaggeration of reflexes and increased postnral reactions. It denotes involvement of the pyramidal tract Contracture, in the same way, is defined as a deformity due to permaient shortening of muscles with or without ankylosis of joints Perseveration, or tonic uncervation, is used in the sense of blocking of passive molement due to insoluntary contraction of all associated muscle groups. Extensibility refers to the normal range of movement of a joint Postural reactions are widespread coordinated reflexes elicited by forcible muscular contraction or by painful stimuli, the prototype is the Babinski sign

Hypotonus

Hypotonus may result from damage to the up per motor neurone as well as from the destruction of the lower — In apoplexy, during the period of shock and in the terminal phases, the hypotonus is quite general, but a hypotonic limb may persist for a long time after interruption of the pyramidal tract. This chronic hypotonia is usually accompanied by diminished extensibility, but sometimes, if the lesion affects the parietal lobe, there may be hyperextensibility and actual muscular atrophy Spastic phenomena such as exaggerated reflexes, synkineses and increased postural reactions, are always present.

The hypotonus resulting from a lesion of the anterior horn cells or of the peripheral nerves is more often accompanied by atrophy than is that due to destruction of the posterior roots as in tabes. The differentiation may often be made by testing the extensibility of the joints, since this is increased and painless in tabes, while it may be increased but painful in polionity elitis, and almost certainly will be decreased and painful in neutritis. The sensitiveness of the muscles to compression is acute in neutritis, and Abadie's maneriver (junching the achilles tendon) serves quite well to differentiate pseudotabes of neutritic origin from the real article. Contractures are absent in tabes, while they often develop in poliomyelitis and in neutritis.

From these two types of hypotonus, the cortical and the neuromuscular, must sometimes be distinguished the cerebellar Tests for coordination will not always serve to distinguish between them, nor will they differentiate between the tabetic and the cerebellar hypotonias lests for coordination jield valid results only when motor power and sensibility are altogether intact. Weakness or spasticity of a limb will interfere with the performance of a movement, while a disturbance in the sense of position will certainly impair its ac-The hypotonus of cerebellar disease is often unilateral, while that of tabes is symmetri-The limits of extensibility are normal in the one and increased in the other, and the reflex activity in cerebellar disease is apt to be normal, while that in tabes, in the stage of hypotonus, is abolished I would call special attention to the importance of the achilles reflexes, since they

may be abolished while the patellar reflexes are The pendular reflex in cases still hyperactive. of cerebellar disease is often of value in determining the side affected. The patient sits sufficiently high so that the feet swing clear, and the degree of back-and-forth movement of the foot is noted after striking the patellar tendon. A similar test may be used on the triceps tendon, the forearm swinging free. The differentiation between cerebral and cerebellar forms of hypotonus is usually easily made, because muscular power remains unaffected in the latter while it is abolished in the former. Moreover the reflexes in the cerebral type are apt to be exaggerated, and synkineses and spasticity are present. Hypotonus with exaggerated reflexes and other signs of spasticity is met with in lesions low down in the posterior part of the frontal lobe cortex and is usually limited to the hand and face.

Hypertonus

Increase of muscle tone is a very common phenomenon in disease of the central nervous system. Aside from the contractures and sclerotic muscular conditions that indicate disease at the extreme periphery, however, hypertonus is generally a symptom of disease of the brain or of its efferent tracts. The problem of differentiation usually narrows down to distinctions between pyramidal and extrapyramidal disease, and the distinguishing features are often difficult to demonstrate, especially in cases of diffuse cortical disorder.

Pyramidal hypertonus, in its minimal state, is characterized by no loss of gross muscular power, but rather by slowness and imperfection of the finer movements. This fact alone, however, even coupled with increased reflexes, will not distinguish pyramidal from extrapyramidal disorders. The Hoffmann reflex occurs in both, but the Mayer sign (forcible flexion of the ring finger produces adduction of the thumb) is absent in pyramidal disease and may be exaggerated in extrapyramidal disease. The presence of this sign is important in Synkinetic reexcluding pyramidal disease. sponses are common in pyramidal disease and absent in extrapyramidal disorders. The Babinski reflex or one of its congeners is the best guide we have to the presence of pyramidal disease, and its homologous hand sign (produced by stroking the hypothener eminence), while less frequently encountered, has an almost equal value. Abdominal and cremasteric reflexes are abolished by pyramidal disease, but not by extrapyramidal disease per se.

The hypertonus of pyramidal disease has a plastic character that is peculiar when well developed. This is due to the so-called lengthening and shortening reactions, the antagonists taking up slack, as it were, so that within fairly wide limits the tonus remains constant. The elasticity,

or snapping back of a limb when stretched and released denotes contracture, and while often found in pyramidal cases, will not of itself distinguish them from extrapyramidal or even from peripheral lesions.

When pyramidal tract signs are present, alterations in muscle tone may throw some light upon the level of interruption. The hypotonus of cortical lesions has already been considered, and the spasticity of spinal lesions needs no elaboration. The distinction between a capsular lesion and a pontile one, however, is not infrequently of importance. In both instances marked hypertonus may result, with spasticity and contracture, limitation of passive movement, and, in milder cases, slowness in volitional movements. In general, the lower the lesion the greater the spasticity and the more precocious its onset. In the pons the pyramidal tracts are divided up into a number of fasciculi, which lie, nevertheless, in rather small compass where they come into relation at three or four different levels with the paramedian branches of the basilar artery. I have been quite impressed with the frequency of small softenings in the pons. The chief distinction between a capsular lesion and a pontile infarction lies in the absence of sensory changes in the latter. A capsular lesion sufficiently large to impair seriously the function of the pyramidal tract will almost certainly destroy fibers in the posterior limb and impair the sense of position in the fingers and The sensory and motor pathways in the pons, however, are subserved by different sets of arterial twigs and hence are usually not involved simultaneously. Crossed paralyses are exceptionally rare in vascular lesions of the pons, however common they may be in tumor cases.

The nearer a small lesion lies to the cerebral cortex the more limited will be the extent of the paralysis and other changes. The cortex is spread out fan-wise, the fibers converging into the internal capsule so that it takes a large lesion to destroy all the cortical fibers while a relatively small one might catch a great many in the capsule. Moreover the foot area lies in a different arterial distribution from the arm and face areas. Pure cortical lesions, as noted above, leave persistent hypotonus. Therefore a monoplegia with hypotonus usually indicates a cortical lesion, while a decidedhypertonic one indicates a small lesion strategically placed at some lower level. The arm is much more frequently the seat of persistent hypotonia than is the leg.

Bilateral spasticity usually indicates a lesion of the spinal cord, but I have observed spasticity of both lower limbs with a "cord" bladder from bilateral lesions of the paracentral lobules. If the face is involved in the spasticity, the lesions must lie above the medulla. Pseudobulbar palsy is due to bilateral pyramidal lesions, but these lesions involve some part lower than the cortex, and their

common locus is the pons.

Among the Extrapyramidal hypertonus. extrapyramidal disorders to be considered from the standpoint of muscle tone, one may include atrophy of the substantia nigra and globus pallidus, leaving aside for the moment the striatal disorders characterized by abnormal involuntary movements. I have been unable to distinguish objectively between the encephalitic destruction of the substantia nigra, and the rare degeneration of the globus pallidus. Most cases of paralysis agitans, I am convinced, are due to nigral atrophy, sometimes associated with rather marked inflammatory manifestations indicating nothing else than chronic encephalitis. The disturbances in muscle tone in parkinsonism are almost too well known to need emphasis, but the maneuver that I have found the most effective in bringing out the characteristic eog-wheel resistance, is a rather wide passive movement of the whole upper limb simulating the overhand swimming stroke. Progressive slowing of movements on repeated opening and closing of the hands or of the mouth, and diminution of the automatic swinging of the hands in walking, are also signs worthy of mention.

The pallido-nigral syndrome (so designated because the pallidum is sometimes affected while the nigra escapes) is to be contrasted with the syndrome resulting from lesions of the cortex, especially of the frontal lobes. The latter condition is seen particularly in senile dementia, lead poisoning, terminal paresis, and in the "central neuritis" of alcoholism and pellagra. In both syndromes spasticity and other signs of pyramidal damage are absent. The tonus of parkinsonism usually relaxes somewhat during continued manipulation, while that of cortical disease usually increases. In the former there is reduction of extensibility, while this is normal in the cortical cases of not too long duration. The hypertonus may be sufficient in either condition to abolish the reflexes. Disease of the frontal lobes may give rise to tremors that may be practically indistinguishable from those of parkinsonism, though at times they come to resemble clonus. The movements have a biphasie character that is peculiar, being termed elonic perseveration. These tremors subside when the patient rests, a differential feature as far as paralysis agitans is concerned. The most important distinguishing feature is the increased resistance to passive movement encountered in the patient with disease of the cortex. The more abrupt the movement the greater the resistance, hence the designation tonic innervation, or tonic perseveration. When the perseveration is quite marked it is apt to be accompanied by reflex grasping, and the clutch reaction may be observed in the foot. To elicit the latter the sole of the foot is tapped lightly with a blunt object at the base of the second toe. Disease of the pyramidal tract usually abolishes this reaction of the toes, and also does away with the grasp reflex. In

parkinsonism some suggestion of the grasp reflex is often found, but the thumb does not participate to any great extent. Moreover, the grasp is not active in character but suggests only that in response to passive extension of the fingers there has been an overswing into flexion. On three occasions I have witnessed a combination of nigral atrophy with senile atrophy of the frontal lobes (proven at necropsy) in which the findings were quite confusing. The condition most often underlying tonic perseveration with reflex grasping is senile degeneration of the brain with many Redlich-Fischer plaques in the frontal lobes. Focal lesions in the posterior part of the superior frontal convolution (Area 6 of Brodmann) or in the underlying white matter will produce these same symptoms provided the pyramidal tract is intact. Evanescent signs of this character may be observed in many acute cerebral conditions.

The distinction between the above disorders and catatonic states is sometimes important. Not infrequently patients have been admitted to mental hospitals with the diagnosis of catatonic dementia precox, which has turned out to be chronic encephalitis. Waxy flexibility is met with only in dementia precox and the resistiveness of the catatonic with its negativism is so different from the placid indifference of the senile and the confused state of the pellagrin that no difficulty should be encountered in distinguishing tonic perseveration from negativism. Reflex grasping does not occur in catatonia. When a patient is "resistive," watch out for perseveration. It has some localizing significance, pointing, I believe,

to the frontal lobes.

Hypertonus is a condition rather generally met with in old age. In some individuals it is accompanied by tremor of a modified intention type rather than the pill-rolling of parkinsonism. Not infrequently the patient with an advanced form shows considerable tonic perseveration, interfering not only with passive movement, but also with active movement. These individuals are often unsteady on their feet, slow in walking, sometimes taking short steps (the "marche à petit pas" of French writers) sometimes walking on a broad base, sometimes showing exaggerated balancing movements of the arms, at other times rather deficient movements with a tendency to topple over.

In the widespread atrophic processes going on in the brain during the senile period it is difficult to separate those conditions of hypertonus due to cortical lesions from those due to disease of the basal ganglia. In the putamen and caudate nucleus, also in the globus pallidus and at times in the thalamus and even in the cortex there is widespread retraction of the tissues from about the smaller blood vessels, indicating atrophy of the so-called molecular type, there being no definite focal lesions. This is the status cribralis, état criblé. Unlike certain other degenerative lesions of the striate body it is not accompanied by in-

voluntary movements like those seen in chorea. Aside from hypertonus and the tendency to tremors, little is found on examination and the signs of pyramidal involvement are absent. How much of the rigidity is due to disease of the basal ganglia and how much to cortical involvement is not altogether certain. I am inclined to favor the basal ganglia since in status cribralis one does not so often get the tonic perservation, and only very infrequently the reflex grasping and groping that are so often encountered in senile dementia.

The Dystonias

The dystonias belong in a class by themselves on account of the presence of involuntary movements which result from constant shifting of muscle tonus from one group to another. term covers a whole group of disorders, such as athetosis, chorea, Wilson's disease and pseudosclerosis, dystonia cerebellaris, dystonia lenticularis, etc. Very often confused with the lenticular group of dystonias is the cerebellar group. both types there may be marked hypertonus, often with deformity and hyperextensibility, exaggeration of involuntary movements by volitional activity, and quieting on rest. Tonus may be exaggerated in some of the cerebellar dystonias, and reduced in the acute choreas. The reflexes are extremely variable and are often impossible to obtain on account of the involuntary movements. I have erred most in attributing the involuntary movements to lenticular disease when they were found to occur in individuals with cerebellar atrophy. As a general rule the cerebellar dystonias remain quiet until stirred into activity, while the choreas cease only during sleep. In the cerebellar cases there is more oscillatory to-andfro movement, while the striatal cases show more complex movements and less stereotypy. presence of considerable atrophy in the lower limbs is in favor of cerebellar disease, since there is so frequently an accompanying degeneration of the spinal cord as in Friedreich's ataxia.

True athetosis is to be distinguished on the one hand from striatal disease and on the other from the pseudoathetosis occurring in tabes and in multiple sclerosis from loss of the sense of position. Athetosis is due to very complete interruption of all the volitional pathways at a low cerebral level, by virtue of which the automatic postural centers in the midbrain are released from higher control. The usual signs of pyramidal disease are present, and one may often elicit the cervical reflex of

Magnus and deKleyn. In the lenticular and cerebellar dystonias there are no synkineses or other pyramidal signs, and the cervical reflexes are absent. Hemiathetosis and post-hemiplegic hemichorea merge imperceptibly into one another. A lesion in the vicinity of the corpus subthalamicum is usually found at necropsy.

It is curious that similar lesions of the corpus striatum (putamen and caudate nucleus) should give rise to so wide a variety of involuntary movements. The abrupt jerky movements of dystonia lenticularis, the slowly progressive rigidity of Wilson's disease, the oratorical style of Huntington's chorea and the terrific contortions of torsion spasm all seem to have very much the same type of lesion. In the whole group the pyramidal signs are absent, the movements are less tremulous, affect the proximal portions of the limbs and the trunk and tend to subside only when the patient is completely at rest or asleep.

Not enough is known about the lesions underlying the involuntary movements in the hemiplegias and diplegias of childhood to attempt localization. It is my feeling that the movements are pseudoathetoses due to loss of the sense of position in the limbs resulting from widespread subcortical destruction. Tonus is usually increased, sometimes with contracture, sometimes with hyperextensibility. Synkineses are always present and often vivid, spasticity is present, and the cervical reflexes are sometimes elicited. The movements are really uncontrolled postural reactions.

Summary

The estimation of muscle tone will occasionally give important information concerning the localization of a pathologic process in the nervous system. Hypotonia may result from a cortical lesion as well as from a peripheral one, but its quality is different. Hypertonia without spasticity may result from disease of the substantia nigra or from that of the frontal lobe. There are differential features, however, that often render a diagnosis possible. Dystonia, with what appear to be involuntary movements, may occur in widespread cerebellar disease as well as in atrophy of the striatum. The differential features of the two forms are discussed. While the distinction between the different categories is sometimes impossible on the basis of muscle tone alone, this phenomenon, taken in conjunction with others, will often lead to correct localization of a disease process within the nervous system.

THE EXTERNAL EXAMINATION OF THE EYE IN THE DIAGNOSIS OF GENERAL DISEASES

II. THE EXTRA-OCULAR MUSCLES, CONJUNCTIVA, CORNEA AND SCLERA By CONRAD BERENS, M.D., and JOSHUA ZUCKERMAN, M.D., NEW YORK, N. Y. The second of a series of three papers read before the Dallas Southern Clinical Society, Dallas, Texas, April 1, 1931.

Outline

- D. Extra-ocular muscles
 - (1) Heterophoria (tendency to "cross eye" or "wall eye")
 - (2) Heterotropia (actual "cross eyc" or "wall eye")
 - (3) Convergence
 - (4) Paresis, paralysis and overaction
 - (5) Congenital abnormalities of the extraocular muscles
- E. Conjunctiva
 - Chronic conjunctivitis caused by focal infection in the sinuses, intestinal tract, and other foci

- (2) Pucumococcic conjunctivitis
- (3) Gonorrheal conjunctivitis(4) Tuberculous conjunctivitis
- (5) Diphtheritic conjunctivitis
- (6) Subconjunctival hemorrhages
- F. Cornea-Corneal Opacities
 - (1) Superficial
 - (2) Deep
 - (3) On posterior surface of cornea
- G. Sclera
 - (1) Inflammation
 - (a) Focal infection
 - (b) Tuberculosis

D. The Extra-Ocular Muscles

Diagnosis of Motor Anomalies—The eyebali is rotated by four recti muscles and two oblique muscles. In order to detect almost all motor anomalies (paresis, paralysis or overaction) which can produce symptoms, it is merely necessary to proceed as follows: Ask the patient to fix a small object at 6 meters (twenty feet) or any distance beyond this; place a card in front of one of his eyes, then alternately shift this card slowly from eye to eye; observe the direction of movement of the eye which is being uncovered. When fixing at 6 meters there should be practically no movement of the eyes, i.e., they should both continue to fix behind the screen.

(1) Heterophoria (tendency to "cross eye" or "wall eye")1—Movement of either eye inward when it is uncovered denotes exophoria (a tendency of the eyes to deviate outward); movement outward denotes esophoria (an abnormal tendency of the visual axes to converge); movement upward denotes hypophoria (the condition in which the visual axis of one eye falls below that of the other) and movement downward denotes hyperphoria (the elevation of one visual axis above the other) which is usually due to underaction or overaction of the vertically acting muscles. It will be noted that the terms exophoria, esophoria, hypophoria or hyperphoria are employed to describe the position which the eye assumes behind the screen. The same procedure is repeated with the patient fixing a small object placed at 25 centimeters (ten inches) and the same movements of the eye behind the screen denote the same anomalies. Exophoria, esophoria, hypophoria or hyperphoria is manifested to the patient by a "shifting" or "jumping" of the test object inward, ontward, upward or downward respectively as the eye is being uncovered. A small amount of exophoria or esophoria when fixing at 25 centimeters is considered normal. This produces a subjective sensation of movement of the object of approximately 2 centimeters at this distance when the card is shifted. Any vertical movement of the eyes seen by the observer or noted by the patient should be carefully studied, because hyperphoria² is a common cause of eyestrain and headache, and may indicate a beginning muscular paralysis.

(2) Heterotropia (actual "cross eye" or "wall eye")—With both eyes fixing a small test object at 6 meters the examiner covers one eye, then uncovers it, meanwhile noting the position of this eye. The same procedure is followed with the other eye. If either uncovered eye moves in, out, up or down to fix the object, heterotropia exists, named in the same manner esotropia, exotropia, hypertropia or hypotropia.

(3) Convergence—To test the near point of convergence, the eyes are made to fix a 2 millimeter black dot on a white card which is carried as close to the eyes as possible until double vision occurs, i.e., until either eye ccases to converge and can be seen to diverge. If the near point of convergence is found to be greater than 75 millimeters (three inches) from the cornea, convergence insufficiency may be suspected. This is a frequent cause of tiring of the eyes during or after close work.

(4) Paresis, paralysis and overaction—The patient is requested to follow a test object (a 1 or 2 millimeter white-headed pin) with both eyes. The pin is carried into various positions in the visual fields and any limitation of rotation of

the eyeballs is noted by the physician. Limitation of movement of either eye in a certain direction denotes paresis (incomplete paralysis) or paralysis of that muscle, the primary action of which is to turn the eye in that direction. Limitation of movement of either eye upward and temporally indicates paresis or paralysis of the superior rectus muscle, the primary action of which is to turn the eye upward in the temporal field; limitation downward and temporally denotes involvement of the inferior rectus; limitation upward and nasally, the inferior oblique; downward and nasally the superior oblique. It will be noted that the superior and inferior recti muscles act in the temporal field and the oblique muscles act in the nasal field. Paralysis of the extra-ocular muscles is characterized by (a) absence of movement; (b) squint, convergent or divergent; (c) diplopia, i.e., double vision. When diplopia is present the paralysis is usually recent. The lesion responsible for the diplopia may be central or peripheral and the paralysis may be caused by hemorrhage, exudate, tumor, periostitis, injury or vascular disturbance producing compression or inflammation of the nerves. Syphilis and epidemic encephalitis are the most common causes. Other causes are diseases of the nervous system: tabes, general paralysis and disseminated sclerosis; infectious diseases: diphtheria and influenza; poisónings; alcohol, botulism and ptomaine poisoning; and vascular disturbances; diabetes and hypertension.

(5) Congenital abnormalities, especially paralysis or paresis of the superior rectus, or fibrosis or paralysis of the external rectus, are not uncommon.

... (6) ,If nystagmus, i.e., an involuntary oscillation of the eyeball, is noted before the eyes are rotated 45 degrees in any direction it may be considered pathologic. Nystagmus usually affects both eyes and is associated with imperfect vision. Usually the abnormal movements of the eyeballs are from side to side (lateral nystagmus) but vertical, rotary and mixed nystagmus are also Irregular · nystagmus, common in Friedșeen. reich's disease and in multiple sclerosis, is not found in paralysis agitans. In true ocular nystagmus the eyes pass and repass the point of fixation and the components are of equal velocity; in labyrinthine nystagmus the cerebral component is rapid and the other component is slow.

E. Conjunctiva

In examining the conjunctiva, cornea, and sclera, natural daylight or artificial daylight illumination is essential in order to detect the presence of jaundice and congestion. Concentrated light is necessary in searching for small ulcers, infiltrations and foreign bodies. For these examinations and for the study of the deeper structures a hand lens and a loupe are valuable. A

strong convex lens is held in one hand in such a manner that the apex of the cone of light produced by it is thrown upon the part of the eye to be examined. The loupe is held in the other hand and the illuminated part of the eye is examined through it.

Conjunctivitis—Congestion of the conjunctiva in mild or (1) chronic conjunctivitis is often associated with chronic infection in the nasal accessory sinuses or in the gastro-intestinal tract. We have also seen congestion and low-grade chronic conjunctivitis in one eye rapidly subside after the extraction of an abscessed tooth.

(2) Pneumococcic conjunctivitis—It is well known that the pneumococcus, the gonococcus and the diphtheria bacillus as well as the tubercle

bacillus may attack the conjunctiva.

(3) Gonorrheal conjunctivitis — In certain cases of chronic gonorrhea there is a mild chronic conjunctivitis without the presence of gonococci. This type of conjunctivitis may recur simultaneously with evidence of the gonorrheal infection elsewhere.

(4) Tuberculous conjunctivitis³—Tuberculosis rarely affects the conjunctiva but occasionally occurs as a yellowish-red irregular lesion covered with secretion. Eczematous or phlyctenular keratoconjunctivitis, considered tuberculous by certain authorities, presents the appearance of small papules surrounded by congestion involving the conjunctiva and superficial layers of the cornea with predilection for the pericorneal zone. These lesions usually occur in children but occasionally adults up to the age of thirty or thirty-five may be affected. The lesions may be accompanied by chronic rhinitis, eczema and swelling of the

lymphatic glands.

Our belief is that many cases of phlyctenular conjunctivitis do not arise from tuberculosis but from sensitization to bacteria in the nasal acsinuses. Phlyctenular conjunctivitis and keratitis of nasal origin have been reported by Wormes and Bidault. In a study, conducted at the New York Eye and Ear Infirmary several years ago, we observed a group of children with phlyctenular keratoconjunctivitis all of whom had adenoids and chronic infection in their sinuses; streptococci were recovered in most of the cultures. On the other hand, Castaris⁵ reports that all of his patients with phlyctenular keratoconjunctivitis reacted to tuberculin intracutaneously; eye symptoms in every instance began to clear immediately when treatment by desensitization with tuberculin was begun. He concludes that phlyctenular keratoconjunctivitis is in all probability a local manifestation of hypersensitiveness of the patient to the tubercle bacillus or its toxins and a tuberculous focus somewhere in the body is the underlying etiologic factor. Whatever the cause may be it is apparently evident that desensitization with tuberculin is a good nonspecific treatment.

(5) Diphtheritic conjunctivitis-It is important to remember that in most cases of diphtheritic conjunctivitis diphtheria is present in the nose or throat. Ehlers describes six cases of diphtheria with diagnosis based on the presence of diphtheria bacilli in the infected conjunctiva. In five of the cases which were observed from their inception a simultaneous diphtheria was found in the nosc and throat. In two cases there was a false membrane. Membranons conjunctivitis may also be caused by streptococci which, in the cases we have seen, have also involved the nasal mucous membrane.

(6) Subconjunctival hemorrhages commonly accompany voniting and whooping cough. Patients who have recurring subconjunctival hemorrhages should be studied carefully to exclude hypertension, chronic infection or metabolic dis-

turbances (diabetes, etc.).

F. Cornea

Certain corneal opacities may indicate general disease.

(1) Superficial punctate opacities, which stain with fluorescein) and also branched opacities (dendritic keratitis) may be associated with chronic infection (virus or bacterial) elsewhere in the body even though Kip beheved that ninety per cent of the cases of dendritic keratitis in America were caused by malaria. In our experience most of these infections are "focal infections" localized in the teeth, tonsils, or nasal accessory sinuses. The elimination of chronic infections, even though they may not be the cause, is sometimes apparently beneficial in preventing recurrences of dendritic keratitis.

(2) Deep infiltration of the cornea—so-called interstitial or parenchymatous keratitis—is caused in ninety per cent of the cases by hereditary syphilis, rarely by acquired syphilis. It is an interesting fact that traumatism is often the exciting cause of this process. Recently we observed this in a young man whose left eye was struck by a piece of metal. Parenchymatous keratitis developed and after a period of three weeks involved the right eye. The Wassermann test was four plus. On close questioning this patient gave a history of chancre. Interstitial keratitis may also be caused by tuberculosis and in certain cases by focal infection.

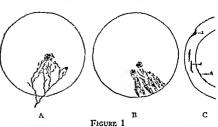

Diagram representing the vorious positions of infiltrations in the cornea according to their depth: A, super-ficial opacities; B, deep opacities; C, corneal opacities: 1, superficial, 2, deep; 3, on posterior surface.

(3) Round opacities on the posterior surface of the cornea—The so-called punctate keratitis of the deep type—are usually associated with chronic infection of the deeper ocular structures eaused by tuberculosis, syphilis, and focal infections. When these deposits are numerous they are usually arranged in the form of a triangle with the apex upward.

G. Sclera

Superficial and deep inflammation of the sclera is usually caused by (a) focal infection or (b) tuberculosis; if the cornea is involved in the process, the condition is called sclerosing keratitis.

IMPORTANCE OF BRONCHOSCOPY IN OBSCURE PULMONARY CONDITIONS Report of Two Cases

By JOSEPH W. MILLER, M.D., NEW YORK, N. Y.

From the Laryngologic and Bronchoscopic Clinic, Beth Israel flospital, New York City Service of Dr. Samuel J. Kopetrky.

THE first case I am about to report will best illustrate the importance of bronchoscopy in all doubtful chest conditions, especially those running a bizarre course for some length of time. The patient, J. M., a journalist, sixty-five years of age, was admitted to the Beth Israel Hospital on January 9, 1932. His chief complaint was intense coughing for over one year's duration with profuse expectoration. He had pneumonia and peritonitis at the age of twenty and ulcers at sixty, but otherwise was in perfect health. There is no history of inhalation of a foreign body, tonsillectomy or recent operation.

About one and a half years ago, he began to cough with profuse expectoration. Four months later he developed bronchopneumonia with fever, sweats, cough and chills. He was in bed two weeks and returned to work in one month. Following this illness he was well except for asthmatic breathing and severe cough with marked expectoration of greenish material. Eight weeks before admission he developed chills, fever, profuse sweats and cough with occasional foul and sometimes bloody expectorations. His temperature was septic in type with remission to 99° for three weeks, after which it became septic again. He lost about twenty pounds in two weeks and became morbidly pale.

On admission his temperature was 103°, pulse 96, respiration 32. Examination revealed a chronically discharging left ear; upper and lower dental plates; and a barrel-shaped chest. There were diminished breath sounds at the right base, with distant tubular breathing above this area. There were also medium moist rales at left base, and occasional rales at right base.

A lung abscess and lung neoplasm were considered as diagnostic possibilities on January 9, 1932.

Laboratory findings: The urine showed considerable glucose on one occasion. The blood count on admission showed 3,840,000 red cells with 62 per cent hemoglobin; 14,000 white blood cells with 82 per cent polys and 3 staff cells. The sputum showed elastic tissue, many pus cells and many gram positive displococci.

An x-ray of chest taken on January 11, 1932, showed effusion into lower portion of right pleural cavity. The posterior portion of the right lower lobe showed evidence of consolidation. The pleura was markedly thickened and the mediastinum and heart were retracted toward side of lesion. The x-ray diagnoses were: Pleural effusion; bronchopneumonia; bronchostenosis and lung tumor.

On January 12, 1932, bronchoscopy was performed under local anesthesia using 10 per cent cocaine and adrenalin. A Jackson 9 m.m. bronchoscope was inserted through the glottis, into the trachea and down to the carina. The trachea was found adequate and its mucosa markedly congested. The carina was found in the median line thickened, obtuse, and intensely inflamed. At the bottom of the right main bronchus, there was a mass entirely plugging its lower end. This mass was enmeshed in foul purulent secretion. Believing that the mass was a lung tumor, a cup-shaped forceps was used in order to secure a good-sized piece for biopsy. The alleged tumor was then seized and brought forth, which proved to be an irregular curved-shaped chicken bone. After its removal the ever-present hacking cough immediately stopped; the purulent material found at the bottom of the bronchus was suctioned off; and the exuberant granulations from the inflamed area removed.

An x-ray examination following removal of the bone revealed the aeration of the right lower lobe improved; but still present are interstitial changes at the base with marked pleural thickening and a small effusion in the costo-phrenic space. Following the bronchoscopy, the patient felt subjectively better; and although he ran an irregular fever, going up at times to 103°, he improved gradually and left the hospital on February 2, 1932, for a country sanitarium, where he fully recuperated in a short time.

Examination of the chest on March 24, 1932, gives the following results: The lung is completely restored to normal after the removal of the foreign body. Aside from a slight thickening of the pleura, there is no evidence of any change. The aeration of both lungs is normal.

The important points in this case are: The bizarre course which the patient ran for over a year; the inability of the x-rays to locate the foreign body; the asthmatic breathing and the dental plates, which probably prevented the patient from detecting the bone.

The second case is that of a beef bone in the right main bronchus simulating asthma and

empliysema.

A married man, forty-nine years of age, presented himself to Dr. Joseph Grubman on July 9, 1932. His chief complaint was shortness of breath, severe cough with slight expectoration and a sensation of choking, especially so before he fell asleep.

Because of a rather vague or indefinite history of having "swallowed" a fish bone about two months prior to consulting Dr. Grubman, he was radiographed on several occasions with negative results. No tuberculosis, new growth or foreign body could be demonstrated.

Physical examination recorded by Dr. Grubman: A well-developed man with a brassy cough and a voice that seemed to be characteristic of laryngeal pressure. Lungs were hyperresonant throughout, expiration prolonged and feeble and accompanied by squeaks and crackles especially so on the right. Having consulted several outstanding clinicians without gaining any more light on the subject, Dr. Grubman decided on an exploratory bronchoscopy.

Accordingly, a diagnostic brochoscopy was performed on patient L. B. at the Sydenham Hospital on November 25, 1932. Under local anesthesia using ten per cent cocaine, to which a few drops of Epinephrin Solution were added, a Jackson 9 m.m. bronchoscope was inserted through the glottis, into the trachea and down to the carina. These passages were found adequate and the mucosa normal.

Entering the main bronchus we found a mass

Volume 33 Number 19

almost blocking the entire lumen. This mass appeared to be enmeshed in sanguino-purulent secretion and scenied to be attached to the left lateral wall of the right main bronchus. It had a cauliflower appearance with a necrotic center.

After the purulent secretion was removed by suction, the mass was sponged dry with cotton applicators and instead of the apparent cauliflower mass it now began to look like a hard bony substance. After several trying attempts I succeeded in delivering an irregularly shaped meat bone with very sharp edges. It was about three-fourths of an inch in length, one-half inch in width and about one-fourth inch in thickness. The concave surface was irregular and rough; the convex surface was rather smooth.

Slight bleeding followed the removal of the forcign body, but the cough soon ceased and the patient left the hospital on November 27, 1932, entirely well.

Comment:—It would be a good plan to refer all chest conditions running a bizarre course for diagnostic brouchoscopy. Many foreign bodies in the air and food passages, especially those organic in character, fail to throw a shadow to rrays. Patients with asthmatic breathing should be referred to the bronchoscopist; for Jackson's slogan should be borne in mind that, "All is not asthmat that wheezes." Last, but not least, patients with upper dental plates have no way in detecting foreign bodies, especially when swallowing soup.

SEQUESTRUM OF THE FRONTAL SINUSES By E. ROGERS NODINE, M.D., FREEPORT, N. Y.

THE literature is not very rich in reports of sequestra following ostcomyclitis of the sinuses, and so the presentation of this

case with recovery seems worth while. Osteomyclitis of sinus origin usually affects the frontal bone, and produces swelling and pain over the frontal sinus. At this stage there is usually scropurulent fluid between the periostium and bone. Necrosis involving the whole bone may follow and extend to other cranial bones through the diploe. If the condition becomes localized, a subdural abscess may form producing a boggy external swelling. Recovery may take place with the separation of sequestra. If the condition arises secondary to operation on the sinuses, the prognosis is poor. A mortality of 100 per cent in post-operative osteomyelitis was reported by McKenzie in the Journal of Laryngalogy, May, 1913, page 179.

A primary case of osteomyelitis of the nasal sinuses always brings with it a history of chronicity along with the acute symptoms.

Case report, Male, P.M., Age 35, was seen in my office in October 1931, complaining of severe frontal headache, nasal discharge, and edema of the right eyelids. The history was that of a chronic frontal sinusitis of ten years duration, with acute exacerbations on the average of five or six times a year. No nausea or vomiting had occurred.

Examination showed tender edema over the frontal region, and marked swelling of right cyclids with exophthalmos of this eye. There was intense headache with no nasal discharge Temperature, 99.8 by month. Intranasally

there existed a high deviation of the septum narrow nares, and a slight purnlent discharge from the right middle meatus.

Intranasal drainage was instituted at once, and x-rays were taken which showed pansinusitis with suggestive necroses of the frontal bone. He did not improve under intranasal treatment, and in view of the x-ray findings an external operation was decided upon.

Under ether anesthesia a modified Killian operation was performed. An incision along the brow was made, the periostium reflected, and the frontal sinus entered by removing the necrotic anterior wall. The interior of the sinus was full of creamy pus which was aspirated; and along with the pus a sequestrum came away about the size of a small lima bean. The sinuscs were very large in all directions, and full of polypoid tissue, which was curetted away. The floor of the sinus was removed, along with the ethmoids and middle turbinate.

While completing the operation it was discovered that the right and left frontal sinuses freely communicated, and the possibility was that the sequestrum was the main sinus septum which had sloughed off and was moving about in the large sinus spaces. All recesses of the sinus were rounded, and eigarette drains were introduced into the nose and the wound angles.

Recovery was uneventful except for a small persistent fistula at the inner angle of the wound, which finally closed under silver nitrate applications. The patient is now well and working.

A STUDY OF THE MATERNAL MORTALITY OF NEW YORK STATE A Preliminary Report

By GEO. W. KOSMAK, M.D., NEW YORK, N. Y.

This preliminary report was presented at a meeting of the Section on Obstetrics and Gynecology of the State Medical Society, April 4, 1933, and has been amended to include the more complete statistics developed since that date by the Department of Health.

N view of the generally unsatisfactory mortality record associated with childbearing in the State of New York among, of course, many others, the importance and value of a study to determine the underlying factors or causes, cannot be denied. A record which, in comparison with the improvement in other fields of medical practice, has remained practically unchanged during two decades, as regards the deaths from sepsis, hemorrhage and other conditions associated with pregnancy, is evidently in need of attention. It has been found that a satisfactory study of the matter must be based on a close examination of individual cases rather than collections of unrelated hospital and other statistics. And therefore the underlying circumstances in each instance must be obtained from the attending physician within a reasonable time after the fatality occurs, while the facts are still fresh in mind. For it is only thus that we can evaluate the particular case and determine the underlying causes, a knowledge of which should be helpful in formulating preventive measures against future contingencies.

A survey of the deaths associated with pregnancy which occurred during 1932 in this State, with the exception of New York City, has been conducted during the past year by the Department of Health with the cooperation of the Committee on Public Health and Medical Education of the State Society. The survey was in line with that being made for the Greater City of New York by a joint committee of the Academy of Medicine and the New York Obstetrical Society, but for obvious reasons the methods employed had to be adapted to different conditions. The officers of the State Department of Health were desirous of making their study with the full cooperation and support of the medical profession and a satisfactory liaison was developed with the Committee on Public Health and Medical Education of our State Society. A Sub-Committee, consisting of Drs. Farmer, Foster and Kosmak, has dealt directly with this matter and it is as a member of the same that I have been delegated to make this preliminary report and to request an endorsement of this important piece of work and a resolution for its continuance. The various County Societies have been favorable to the scheme with the exception of two which opposed that phase of the study which permitted a State physician in place of the family doctor to obtain information from the family. This objection, I am informed, has been adjusted satisfactorily.

As already stated, the value of a survey of puerperal deaths depends on a study of individual case records, supplemented by a personal interview with the attending physician. This constitutes a problem of considerable magnitude, but it has been attempted by the Department's specially designated physician investigators; and the partial results of the first year's work, namely those of 1932, are herewith presented for your comment and approval. If the project meets with the support of the profession in an earnest effort to learn and to make use of the information for the good of pregnant women, then definite plans must be formulated for the continuance of the investigations over a longer period before satisfactory final conclusions are possible; or the survey should be made a continuous one with periodical publication of the maternal mortality figures and a cumulative report of comparisons at Thus, by keeping the subject stated intervals. constantly before the profession, more permanent good may result than by sporadic and unconnected reports. The State Department of Health would seem to be well organized to do this through its ably conducted Division of Maternity, Infancy and Child Hygiene, and we bespeak for these efforts the support of the physicians of the State. The Director of the Bureau, Dr. Elizabeth M. Gardiner, is to be particularly commended for her enthusiasm, personal labor and interest.

The medical profession must accept the responsibility of reducing unnecessary deaths associated with pregnancy; and it must be accepted that a certain proportion is needless. This can be accomplished, I believe, by a due appreciation of the lessons which are taught by the results of such investigations as that under consideration. In carrying out a study of this kind one of the most essential purposes, as already stated, should be an analysis of the factors dealing with preventability. It was found in other and similar investigations that approximately four avoidable factors entered into the question of puerperal mortality: (1) omission of, or inadequate, prenatal care; (2) professional negligence, errors of judgment, or incompetency; (3) improper environment or lack of facilities; and (4) contributing negligence on the part of the patient or family.

The individual case records included in the present study were classified in the usual fashion according to cause of death, and likewise with regard to the factor of preventability, as just outlined. A member of your committee has gone over the year's case histories with the Chief of the Division of Maternity, Infancy, and Child Hygiene; and while in many instances the records were unsatisfactory, it was possible in many cases to establish, at least in part, the preventability factor. Conclusions will be ventured later on.

Unfortunately it is not possible to present a complete and satisfactory report of this survey because of lack of time and opportunity to study the results, but there is enough material on hand to present certain general conclusions and to show the desirability of continuing an effort to stabilize, if nothing more, some of our obstetrie methods and procedures. May I therefore summirize the statistical findings thus far obtained

During 1932 there occurred in New York State outside of the Greater City, 642 fatalities associated with pregnincy. I his number includes 126 cases of abortions and ectopics, and 123 cases in which the actual cause of death was believed to be non puerperal (cardiae, pulmonary and other intercurrent diseases). This leaves for consideration 285 deaths which may be divided into six groups according to the chief cause, as follows.

Otths accounting to the other cames, and an	
Sepsis	85
Hemorrhage	68
Toxemia	66
Embolism	32
Miscellaneous, associated with surgical procedure	31
Miscellaneous, associated with other eauses	3
•	285

The majority of deaths, 243, or 85%, occurred in hospitals. Of these more than half may be regarded as emergency eases, including 35 delivered at home and brought to the hospital when complications developed after delivery (See Table I)

Only 27% of the total cases had received adequate prenatal case, 45% had madequate, and 27% no prenatal care at all (See Table II)

Operative procedures were employed in 63% of the cases 36% of which were cesarean sections, 26% forceps deliveries, 26% versions and 13% induced hibor or other procedures (See Table III)

Thirty eight per cent of the cases were primparae, 57% multiparae and 5% not stated (See Table IV)

Seventy per cent of the deaths were associated with full term deliveries (See Table V)

A brief analysis of each of the groups of deaths classified by cause shows that prenatal care in the 85 deaths from sepsis was inadequate or entirely lacking in 67. Seventy seven of the sepsis deaths occurred in hospitals, but 24 were admitted after delivery elsewhere. In 49 or 58% some operative procedure was associated with delivery, and in 7 instances these procedures were followed by major abdominal operations during the puerperium. The operative procedures included 13 cesareans, 15 forceps deliveries and 10 versions. Some non puerperal disease was mentioned in connection with 59 of the septic deaths.

In the 66 deaths from toxenin only 14 were strict to have had adequate prenatal care. In but 28 cases was a spontaneous delivery recorded Cesarean was done in 17, version in 10 and forceps in 6. It may be called to your attention that where stated, the anesthetic used was chloroform in 7, and spiral anesthesia in 6.

There was 68 deaths from hemorrhage, 37 of which were associated with some type of placental anomaly. Rupture of the uterus occurred in this group 5 times and version was performed 18 times. Cesarean section was done in 13 cases of which 6 had contracted pelves.

The deaths from embolism numbered 32, among which there were 18 preceded by operation

In the miscellaneous group of 31 deaths after surgical procedures, 16 followed cesarcan section, 6 versions and 9 forcens. Long labors were present in more thin one third, mostly associated with cesarcan section. In the other miscellaneous group of 3 there were 2 deaths from puerperal psychoses.

It is not practical to present the detailed figures in this report, which must be regarded as preliminary, but these will be published in due course. However, to those who studied the ease histories a few observations may be permitted, among which the following are of especial interest

A large proportion (45%) of these fatalities occurred in women who failed to register with any physician or hospital until late in pregnancy or mactual labor

A considerable number of cesarean sections were "emergencies," often preceded by unsuccessful attempts at forceps or versions

There were many very long labors preceding operative deliveries, with the consequent bad risk of an exhausted patient. One hundred and forty-four, or 80%, of the operative cases were stated to have had labors from 12 to 100 hours. The coareans in this group averaged 40, the versions 37 and the forceps deaths 30 hours each

The factor of contracted pelvis was not recognized during pregnuncy in many instances, and even if recognized no plans were made for lospitalization or appropriate delivery

Too little attention was paid to intercurrent disease, with no intelligent planning for cardiac cases for example, hospitalization being post poned until a late period

There are many instances in which high blood pressure, edema and albiminum were noted in the final weeks, which had been under prenatal care and jet no effective measures were employed to properly evaluate these warnings of an impending eclampsia

One is impressed in studying a series of cases such as this that more information is needed about environmental conditions, about the competency of individual operators, about the lack of and the greater need of education in proper maternity

care of both the public and physicians. The pregnant state, notwithstanding all the efforts which have been made in this direction, does not seem to command or receive the attention which it merits.

In order to make a study of this kind of value, some conclusions should be reached as to how many of these deaths should have been avoided. Although the case histories were gone over with this in mind, I do not feel competent to make any absolute statements in this respect, but I would venture my personal belief based on a review of 285 puerperal cases, excluding abortions and non-puerperal deaths, and classified according to the formula already previously mentioned, that over half could be ascribed to faulty management, either by the doctor or the hospital, over 17% to the personal negligence of the patient or her

family, and a very few to midwife participation, thus leaving about 30% of the total in the non-preventable class. The latter also includes the doubtful and undetermined cases. (See Table VI.)

It is quite evident, therefore, that a knowledge of the mortality associated with the pregnant state must be effectively disseminated, so that the lessons to be learned from a study of obstetric practice in any given community will lead eventually to improvement in the care of our prospective mothers. Moreover, it is essential that the feeling of fear, of uncertainty and even of suspicion, which results from the presentation of such unfavorable figures be clarified and eliminated. It seems to me that this is strictly a medical problem to the solution of which the organized medical profession must lend its moral support as well as its qualified technical assistance.

POSTGRADUATE MEDICINE AND THE GENERAL PRACTITIONER

By ALAN R. ANDERSON, M.D., NEW YORK, N. Y.

From the Administrative Board on Postgraduale Studies in Medicine, Columbia University.

TN the past ten years a remarkable amount of interest has been evident in the field of postgraduate medical education. The responsibility for the quickening of this interest has not been centralized, but has been distributed among such widely diversified agents as national, state, and county medical societies; educational agencies such as the Council of Medical Education of the American Medical Association; medical schools; academies of medicine in our larger cities; and by various specialistic medical and surgical bodies too numerous to mention. Postgraduate training has been featured in medical periodicals, and comprehensive reports by medical commissions have reviewed the present status of graduate training and have suggested plans for the future.

In the present article some of the trends of postgraduate training as it concerns the general practitioner will be indicated. No attempt will be made to review the advances being made for the training of the specialist, nor will there be mention of courses having a particular appeal to the specialist. Some excellent discussions have been contributed to this field, particularly by Cutler,1 Rappleye,2 Hener,3 Dannreuther,4 Mecker,5 Mac-Pherson, McCarthy, by the Report of the Commission on Medical Education (1932), the yearly reports of the Council on Medical Education of the American Medical Association,8 and the bulletins from the National Boards of Oto-Laryngology, of Ophthalmology, and of Gynecology and Obstetrics.

It has been gratifying to note the active part that the state and county medical societies have taken in developing the postgraduate program for practitioners. It is safe to say that in many counties in New York State and elsewhere the atmosphere of the medical meeting has been completely changed by the emphasis that has been placed on education in planning medical programs. The county is the logical medical unit of the state. The county is and should be willing to let the specialist shift for himself; but the county through its medical society should be everlastingly aware of its obligation for the continuation education of its general practitioners. should be no danger of state medicine in a county where vigorous, progressive physicians united in an active medical society are working in cooperation with a well managed community hospital and intelligent health agencies.

One of the first attempts to carry postgraduate training to the doctor was made in North Carolina, where in 1916 an itinerant clinical course was given successively to six groups of physicians. Slightly different itinerant courses have been carried out in Wisconsin, Minnesota, and

Kansas. Other states that have conducted similar clinical courses include Michigan, Pennsylvania, Ohio, Missouri, West Virginia, Colorado, Iówa, and Oklahoma.⁹ Plans have been made by the New England Medical Council to carry to a number of rural New England communities all of the essential apparatus to teach general practitioners the fundamental principles of the treatment of fractures.¹⁰ Information regarding the treatment of fractures has been exceedingly well distributed by national and regional committees on fractures.

In the counties of New York State another form of graduate education in which medical courses have been brought to the doctors has been fostered. Under the aegis of the Committee on Medical Education and Public Health of the State Society, correlated series of clinical lectures have been given for the past six years at the meetings of the county medical societies. recent report of that Committee indicates that to date 116 courses comprising 632 lectures have been given in 47 different counties of the state.11 This means that approximately 70 per cent of the membership of the State Society has been reached by these correlated courses. The clinical lectures have been given by well known clinicians and surgeons for the benefit of practitioners of medicine, and a majority of the subjects have been in the field of internal medicine.

In the more populous sections of New York State the county societies have taken the initiative in establishing postgraduate courses. A good example is the series offered each year by the Kings County Medical Society in conjunction with the Long Island College of Medicinc. Outside of New York State educational plans sponsored by county societies that have recently come to our attention are those of the Allegheny County Medical Society (Pennsylvania), and the Mahoning County Medical Society (Ohio). Another very stimulating type of postgraduate course is the Graduate Fortnight of the New York Academy of Medicine, which has attracted each year for the past five years a large number of medical visitors. It goes without saying that urban communities, especially those that have within their eonfines one or more medical schools, can offer to their physicians more advantages in postgraduate training, elinical and pathological conferences. and section meetings at the various academies of medicine. The urban practitioner has plenty of graduate instruction within his reach if he will only take advantage of it.

A departure from the clinical lecture type of course in favor of a "clinical conference" plan is being advocated this year by the Committee on Medical Education of the New York State So-

ciety, and it is suggested that this plan be tried in some counties as an experiment. "The scheme of a clinical conference is to have physicians in an area bring to the meeting some half dozen cases which present concrete problems either in diagnosis or treatment. These cases should be brought to the center where the meeting is to be held, early in the day, thus allowing the guest chief of the clinic an opportunity to study these cases. Then, at the time of the meeting, the patient's physician presents the case and gives his point of view. The patient is shown and the case is opened for general discussion; and finally the guest chief summarizes his own findings, expresses his own opinion and makes his recommendations." 12 This plan is fraught with great possibilities, since it places the local hospital where it ought to be, at the center of the community's medical life, and gives the local physicians almost complete charge of a very practical program. Skilled clinicians should have no difficulty in making noteworthy contributions to the knowledge of the practising physicians in such practical problems as tuberculosis, heart disease. diabetes, infant feeding, and gastro-intestinal disorders. It would seem that, wherever postgraduate training is carried to the local groups, it can best be done by some such plan as this. Several of the rural hospitals under the Commonwealth Fund have had success with just this type of clinical conference. A very interesting document setting forth what the outlying hospital could do in postgraduate medical education was written by Dobson in 1921.

A complementary plan, and one that offers advantages not available to the average community hospital, is the establishment in large centers of practical clinical courses of one week's duration. These courses should be held at any time of the year when a sufficient number of applicants are available, and the schedule should be sufficiently elastic to meet the requirements of the general practitioner. In the large clinics and wards of our leading hospitals, clinical chiefs in pediatrics, internal medicine, obstetrics, tuberculosis and cardiology will have every opportunity to present a number of medical problems, with all the confirmatory evidence of the pathological, bacteriological, chemical, and roentgenological labora-Furthermore, in the large urban clinics, the general practitioner can get a more adequate approach to the control of gonorrhea and syphilis, to public health problems, to the care of school children, to mental hygiene, and to certain phases of industrial medicine. In each course of one week several hospitals, a variety of clinical services, and public health agencies would be utilized. One such plan has been presented by the Committee on Medical Education of the State Society, and a description of several tentative oneweek courses was published.

The medical schools of New York State have for many years offered postgraduate instruction to the general practitioner. Those listed in 1932 as having approved postgraduate courses by the Council on Medical Education of the A.M.A. are: Albany Medical College, Columbia University (including the New York Post-Graduate Medical School, Vanderbilt Clinic, Neurological Institute of New York and the New York State Psychiatric Institute and Hospital, and the affiliated hospitals. Mount Sinai, Saint Luke's, and Montefiore), Cornell University Medical School. New York Eye and Ear Infirmary, New York Polyclinic Medical School, Trudeau School of Tuberculosis, University and Bellevue Hospital 'Medical School, and University of Buffalo Medical School. Space does not permit a discussion of the variety of courses offered by these medical schools. It is sufficient to say that the general practitioner can find almost any type of course that he wishes, either part time or full time, and he can spend at this work a few hours a week or he can devote himself for several weeks full time to the study of medicine. In New York City the efficient Bureau of Clinical Information at the New York Academy of Medicine has made available to all medical visitors a summary of postgraduate opportunities in New York and Brooklyn, as well as a calendar of the daily clinical conferences in the large hospitals.

What can the practicing physician hope to get from the postgraduate programs locally and in the large centers? So much depends on the native ability, medical education and practice, and the aspirations and ideals of the individual practitioner that no ready answer can be given to this question. It has been pointed out in the report of the Commission on Medical Education that the capable general practitioner is well qualified to handle 80 to 90 per cent of the illnesses he is called on to treat. 15 But he does need to be kept informed of the recent advances in medicine, and those less capable need a more basic training than that. In a general way the benefits to be expected from postgraduate courses may be grouped under the following headings: (1) a more thorough understanding of the fundamentals of physical diagnosis, history taking, and the rationale of differential diagnosis, (2) an appreciation of the usefulness and limitations of laboratory aids in medical practice. (3) a practical survey of modern treatments of a variety of diseases, the management of which falls largely to the lot of the general practitioner, and (4) an accession of that intangible something usually referred to as morale.

It is difficult to get physicians in practice to realize the importance of physical diagnosis and history taking. Many clinicians feel that these are studies for only the undergraduate medical student, and that it is an affront to the doctor's in-

telligence to insinuate that lie cannot make a thorough physical examination or take a eareful his-And yet it is only necessary to think of the intricacies in the physical diagnosis of those patients one sees in eardiac, chest, gynecological and neurological clinics to realize that the recent graduate, no matter how good his medical education or his hospital internslup, cannot possibly get all the refinements. And many of the older hysicians, furthermore, have not had the advantages of modern medical training. Some of the points in physical diagnosis to be stressed are value of percussion and auscultation in examining the heart and lungs, appreciation of cardiac murmurs, altered breath sounds, and rales, palpation of the neck for thyrnid enlargement, correct examination of the nerves of special sense, determination of exophthalmos and increased intra-ocular tension, appreciation of motor and sensory (touch and pain) disturbances, pelvie examinations leading to correct diagnoses, rectal and prostatie examinations, and blood pressure readings These are only a few of the more important elements which constitute a complete physical examination

The use and abuse of laboratory data in arriving at diagnostic conclusions have been widely discussed in recent years. It is generally agreed, however, that, in the great majority of clinical problems, whether a diagnosis is fairly evident or not, a few laboratory tests are mandatory Among the more important may be mentioned urinalysis, estimation of hemoglobin, white and red cell counts differential counts, and staining of smears for gonococci, tuberele and diphtheria bacilli It would seem that every active practitioner should be able to properly evaluate these tests Somewhat more complicated tests that will not be done in the practitioner's office, but which at times he will have oceasion to use are the estimation of the sugar and urea content of the blood, examination of spinal fluid blood cultures, Wassermann test, analysis of stomach contents and feces, and the estimation of basal metabolic rates under laboratory data should be mentioned such tests as the Mantoux and the Schick The knowledge a general practitioner should have about roentgenological diagnosis is a moot question Certainly he should know enough to choose intel ligently a competent roentgennlogist to make interpretations for him, and he should be able after sceing the report to visualize fairly accurately the pathological changes that have occurred

Many practitimners wish to touch rather lightly on the diagnosis, and concentrate on treatment Winle this is a misplacement of emphasis, considerable attention must be given by the teacher to those forms of treatment that have been intro duced successfully within the past ten or fifteen Methods of treatment that will be in demand are the use of insulin in diabetes, management of anemias by liver and iron, use of arsphenamines, infant feeding (an important topic), management of obstetrical problems, use of digitalis and other cardiac drugs, treatment of arthritides, and the technique of intravenous and intraspinal therapy Psychotherapy (not psychinanalysis) should have a place in the practice of every doctor, and nearly every one is using it consciously or otherwise. In all forms of treatment, prescription writing, although having its place, should not be unduly stressed

An important by-product of any postgraduate training is an increase in the morale of the student physician Graduate training means for one thing a break in the routine of practice, it takes the doctor back to the atmosphere of pleasant undergraduate medical days, and it brings new thoughts and ideas to minds that have too often grown rigid. The reading of incdical literature has been one of the chief antidotes against the feeling of staleness that inevitably comes to one in the practice of medicine Graduate training in its simplest form is this practical literature made vivid by personal contacts with stimulating The renewed interest in a medical chnicians practice which comes to the practitioner after a visit to the hospital ward or clinic of such a clinician can be appreciated only by one who has had such an experience

PHYSICAL AND CONSTITUTIONAL MEASURES IN CHRONIC ARTHRITIS By RICHARD KOVACS, M.D., and JOSEPH KOVACS, M.D., NEW YORK, N. Y.

Read before the Session on Physical Therapy at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 6, 1933.

THRONIC arthritis causes more prolonged disability, suffering and economic loss than any other chronic disease including tuberculosis. The medical profession is striving earnestly to solve the problem of its cause and to find its effective remedy. In recent years under the dominating influence of modern bacteriology the theory of focal infection has been propounded as a prime etiological factor. It is generally conceded that in both types of chronic arthritis, the rheumatoid and the osteoarthritic, a low grade microbic infection is present. The consensus of opinion inclines towards considering chronic arthritis as a streptococcus infection, yet in spite of a huge amount of research work, up to the present time it has been impossible to find the specific microorganism. It has not yet been decided which strain of streptococcus should be accepted as the causative microorganism. On the other hand, Crowe indicates as a frequent cause of arthritis a staphylococcus, the micrococcus deformans; Loewenstein and Reiter are in favor of the bacillus of tuberculosis, while still other research workers believe that colon, dysentery and pneumonia bacilli are responsible.

It is a well known fact that most of the above mentioned bacteria can be always found in the nose, throat, mouth and bowels of perfectly normal persons. There are also many individuals who harbor dental, tonsillar, prostatic or other foci of infection for many years, yet do not show

any signs of arthritis.

Considerations such as these must lead to the conclusion that there must be also some other factor responsible for the development of the disease. Bacteria take hold only in an organism in which they find an appropriate nutritive soil. Bacteria of the type held responsible for arthritis will thrive only in a body with lowered resistance—with an arthritic diathesis, an increased susceptibility towards chronic infections. A lowered resistance as a rule depends on the constitutional make-up of the individual and this introduces a consideration of the "constitution" as one of the main factors in the development of chronic arthritis.

What do we mean by constitution? It signifies that complex of conditions which determines the reaction of the individual both against physiological (normal) and pathological (harmful) external and internal influences. The important function of the constitution is its ability to counteract any disturbances and to adapt the body to changed conditions. Two factors are recognized in the formation of an individual's constitution: One of these is the genotypic factor—the qualities inherent in the germ plasm. In a large series

of cases studied by Pemberton and Pierce¹ heredity played a very great role in the background of chronic arthritis. The other factor is the paratypic, the effect of environmental influences. Environmental forces modify the individual's constitution constantly. Infectious diseases of childhood, unfavorable housing, lack of light, air and exercise, improper or insufficient food, all exert a potent influence on the constitution.

In recent years consistent efforts have been made to classify individuals according to constitutional types. A classification is based mainly on antrophologic measurements, and we accept that of Borchardt,² differentiating between the asthenic or feeble, and the pycnic or robust type of individual.

Studies by Osgood,³ Goldwaith,⁴ Swain⁵ brought out the significant fact that there is a close connection between these two types of body constitution and the two types of chronic arthritis. Anthropometric measurements by one of us (J. K.) at the arthritis clinics of the Postgraduate and the St. Luke's Hospital have further corroborated the fact that the infectious or rheumatoid type of arthritis appears mostly in individuals belonging to the asthenic type, while osteoarthritis is as a rule found in those of the pycnic type. We believe that the different forms of chronic arthritis can be explained on the basis of different body types:

TABLE I
Constitutional Types in Arthritis

Asthenic Type
Long, narrow body
Long neck
Gracile bones
Feeble—Inclines to ptosis
Lack of fat
Hypotonic
Anemic
Poor in connective and
mesenchimal tissues
Often hyperthyroid
Lowered capacity for anti-

Pycnic Type
Shorter, broad shouldered body
Short neck
Large bones
Robust—Tendency towards obesity
Fat retention
Hypertonic
Plethoric
Abundance of connective tissues
Often hypothyroid
Increased response to stimulation

When in the asthenic type resistance becomes lowered as through harmful external effects and an arthritic diathesis is present, a more active form of infection will appear, the rheumatoid type of arthritis, characterized by an exudative type of inflammation with proliferation of the synovial membrane and perichondrium.

On the other hand, in the pycnic type an arthritic infection involves a slow degenerative process, and the affected joints present a picture of a

dry osteoarthritis.

It is our belief that the two generally recognized types of chronic arthritis, the rheumatoid and the osteoarthritic, are brought about by identical etiological factors, and their different manifestations are based on the difference in body constitution. It must be recognized, however, that we frequently meet with mixed body types, and generally we find the mixed form of arthritis in them.

A different body type in itself does not represent abnormality or increased susceptibility to different diseases, it takes harmful external effects to develop a morbid constitution, an arthritic dia-Diathesis ethmologically means disposition. It signifies an anomalous morbid constitution which no longer belongs within the confines of normal variability but already represents a potential disease condition. From a clinical standpoint, the following factors have been shown to contribute to the development of an arthritic diathesis.

TABLE II

Factors in the development of an arthritic diathesis

- Previous disease of infectious or inflammatory nature.
- Unfavorable climate.
- Damp dwellings. Lack of sunlight.
- Lack of exercise. Bad posture.
- Improper diet (lack of Vitamine B combined with carbo-hydrate excess) and over eating.
- Dysfunction of the digestive system (constipation).

 Disturbed function of the skin (instable thermoregulating mechanism—reduced skin elimination). 10.

Disturbed capillary blood circulation.

Dysfunction of the endocrine system (ovarian-11. thyroid glands).

12. Fatigue, worry, anxiety.

Constitutional Therapy in Arthritic Diathesis .

The aim of a rational treatment of chronic arthritis is based primarily on the climination or amelioration of the arthritic diathesis by means of a constitutional therapy and, secondarily, the relief of the local changes. It is self-evident that regaining the full vitality of the body gives the best hope for the restoration of local pathological changes, if not too far advanced, and it is also evident that different types of abnormal body constitutions will require a somewhat different type of constitutional therapy.

A careful regulation of the hygiene of daily life plays an important part in the constitutional therapy. Regular living habits, well planned exercises, proper posture for improving faulty body mechanics, suitable clothing are essential parts of any plan. Regulation of the digestive function, especially the correction of any variety of constipation, a suitable diet, an adequate hormonic stimulation and, finally, an increase of circulation are all important links of a constitutional therapy.

As to diet, a high vitamin low carbohydrate content is indicated in both types of arthritic

Pemberton1 believes that low manifestations. calorie intake will benefit every type of case; we agree to this as far as the pyenic or robust type is concerned, but are of the opinion that in asthenic types, in people with anemia and a tendency to "emaciation," no restricted diet should ever be applied. A recent article by Snyder and Traegers contains a wealth of sane and useful information on this angle of the subject.

Remedial agents to increase the circulation are indicated in both types of arthritis. In the rheumatoid type the circulatory disturbance is more due to a spasm, a disturbed innervation of arterioles and capillaries, and treatment must be Physical therapy directed toward this spasm. measures are of foremost importance for this purpose, also in some eases histamin substances administered subcutaneously or through electrophoresis (ionization) are effective.

In osteoarthritis, where a plethoric state and high blood pressure is generally present, to increase the blood circulation venesection or bloodletting is one of the most effective therapcutic measures. Removal of 300 to 500 c.c. of venous blood decreases the blood volume and viscosity and increases the speed of the circulation.7 Hess' showed in dog experiments that in addition to the increase of blood circulation, the circulation of lymph also increases. The amount of blood taken at a time should depend on the blood pressure and on the amplitude of the pulse. It may be preferable as a rule to remove a smaller amount-250 to 300 e.e. at first and repeat the venesection three to four weeks later, taking a larger amount the second time. When ostcoarthritis is connected with hypothyroidism, thyroid medication often brings prompt relief. climacteric arthritis ovarian preparations do not seem to show satisfactory results, while the removal of 200 to 300 c.c. of blood often does.

We may sum up the principles of constitutional therapy in the two types of chronic arthritis as

follows:

TABLE III

Constitutional therapy in chronic arthritis Rheumatoid arthritis (asthenie constitution)

Roborant and tonic therapy.

Normal caloric, low carbohydrate, rich vitamine and mineral diet.

Increase weight and fat deposits.

Stimulation of hemato-poetic system, blood transfusion, Stimulation of antibody formation (vaccine, foreign protein, fever therapy)

Relieve increased capillary and arteriolar tone (physical

therapy and histamin products).

Osteoarthritis (Pycnic constitution) Eliminative and reducing therapy.

Low calorie, low carbohydrate, rich vitamine and low mineral diet.

Reduce weight and fat deposits. Deplethorizing, blood letting.

Increase excretion and secretion through diuretics, cathartics, skin irritation.

Increase circulation and metabolism (physical therapy and thyroid medication).

Vaccine therapy has its legitimate place in the treatment of chronic arthritis. When a definite bacterial infection is found, vaccine therapy may be applied but we may rest assured that it will influence but one factor; it leaves the arthritic disposition unchanged and the patient may get within a short time a new bacterial infection from the same type or another type of germ. In performing sensitization skin tests, it often happens that after two or three months of vaccine treatment a positive skin reaction occurs with a different type of organism. If a definite focus of infection can be proved it should be removed, although spectacular and prompt results after such surgical intervention are an exception and not a rule. We believe that a thoroughly administered constitutional therapy is essential for overcoming the original endogen cause of the arthritic diathesis and in many cases it will eliminate the foci too.

Physical Therapy in Chronic Arthritis

Physical therapy in chronic arthritis fulfils a two-fold object: (1) It serves as part of a constitutional therapy in increasing circulation and influencing metabolism, in promoting the activity of the digestive tract and in correcting faulty body mechanism. (2) It relieves and prevents local arthritic changes, pain, stiffness, exudation, muscular contracture, atrophy and weakness. Physical measures must be employed in every case according to a carefully individualized plan which takes into account the pathological changes present as well as the constitution and social circumstances of the patient.

Physical therapy will afford maximum benefit if it is employed early in the disease and is properly coordinated with other constitutional measures, and is continued consistently for a sufficiently long period. There should be no polypragmacy, but rather a suitable alternation or combination of general and local measures. A certain change of methods is at times unavoidable in a definitely chronic condition like arthritis, and hence the advantage of drawing on the large variety of circulatory stimulants offered by physical therapy. (See Table IV.)

TABLE IV

Physical therapy in chronic arthritis 1. General or systemic measures

 Heat: Hot water baths, electric light baths, general diathermy, hyperpyrexia treatment. Galvanic baths with or without additional skin stimulation.

2. Heliotherapy, natural and artificial.

3 Exercise: Carefully supervised physical training and medical gymnastics.

General massage.
 Colonic irrigations.

2. Local measures

 Heat: Luminous heat and infra-red radiation. Diathermy. Hot air douche. Monoterminal high frequency (Oudin) current. 2. Galvanic current. Histamin iontophoresis.

3. Massage.

4. Voluntary and passive exercise.5. Static wave current for decongestion,

6. Low tension wave currents for muscle exercise.

A. Systemic or Constitutional Measures

1. Heat. Hot water baths with or without additional chemical stimuli, contrast baths, electric light baths, steam and hot air baths, general diathermy, autocondensation, and the newly inaugurated method of short wave fever therapy, all belong among the large variety of thermal Age old empirical experience, extended clinical observations, (Pemberton^o), and recent physiological research (Bazett¹) all point to the fact that such measures are potent agents influencing circulation and metabolism. Changes in the body temperature following general heating result in the acceleration of the pulse rate, an increase of the circulation rate and a general vasodilatation in the skin. The circulating blood volume is increased, while the alveolar CO₂ tension and the alkalinity of the blood show a decrease. Respiration is affected at a rate of 5 to 6 respirations per minute per 1° C. (1.8° F.) rise in rectal temperature. Metabolism always shows a considerable increase on any increase of body temperature. These physiological effects may be varied in intensity and extent according the nature, degree, duration and interval spacing of thermal treatments.

The clinical object of systemic heat therapy is the amelioration of the arthritic diathesis by the stimulation of general circulation and the increase of body metabolism; the local changes are only indirectly affected, yet in many instances following general thermal treatment there is a decrease of pain and swelling and functional improvement in the affected parts

improvement in the affected parts.

The selection of a systematic thermal measure must be made on the basis of seasoned clinical experience and within the limits of the expected individual tolerance. The patient's social circumstances and the question whether the measures are to be applied at the home, in the doctor's office, in an institution or a health resort also enter into consideration.

The hot water bath is perhaps the simplest and most everywhere available general thermal measure. It may be started at a temperature of from 96° to 99° and gradually carried up to 102,° employed from five minutes to half an hour, two or three times a week. It should never exhaust a patient. Fragrant pine extracts or other resinous substances, or vile smelling sulphur mixtures are often recommended as an addition to these hot baths, with all kinds of extravagant claims; the only effect of these substances is an additional mild stimulation of the skin, especially when gentle friction is employed with the bath. A galvanic current passed through a warm bath

exerts a marked stimulating effect but no specific curative virtues, contrary to the claims of the commercial promoters of these "electric" haths. Prolonged hot baths or hyperpyrexia baths are very exhausting and must be employed only with due care in selected cases of rohust constitution. The same precaution relates to an additional application of a cold or an alternating hot and cold water application, known as a Scotch douche. In suitable cases it adds to the general stimulating effect by neuromuscular "toning." The same effects can be adapted to home use by means of a cool bed sponge.

Electric light cabinet baths, steam and hot air baths are being employed in the institutional treatment of chronic arthritis of the robust constitutional type. General light baths from high wattage (1500 or more watts) incandescent lamps, applied for half an hour or more may be conveniently administered in physicians' offices instead of the somewhat more exhausting cabinet baths. General diathermy, or in occasional instances autocondensation also offer a means for general thermal effects in office practice.

High frequency fever treatment through a powerful diathermy apparatus or through a short wave apparatus (radiothermy) offers a new and not yet fully evaluated institutional means for profound constitutional effects on chronic arthritis. Carpenter and Warren¹¹ report some striking results in infectious types of arthritis. In a limited series of cases of ours under treatment the failures and the encouraging results were about equally divided but good results were particularly evident in chronic gonorrheal arthritis.

None of the general heating measures should ever be instituted in a haphazard way and without definite indications. Provision must be made for patients to cool off and rest after any general heat treatment. A well planned course of general thermal measures should be followed by a period of no treatment or be alternated with suitable local therapy. It is not avisable to employ vaccine therapy during a course of general heat treatment.

2. Heliotherapy-natural and artificial. benefit of either natural or artificial light treatment in tuberculous arthritis is explained through the constitutional effects of the irradiation and those of elevation, mountain air, rest and re-The good results reported in nontuberculous chronic arthritis after sojourns in heliotherapy resorts, or after artificial radiation, are undoubtedly partly from the general tonic effects of radiation, especially on patients with asthenic constitution and rheumatoid arthritis; in addition, the recent research work shows that chemical, thermal and other "insults" of the skin provoke or increase the defensive power of the body by a direct effect on immunity and by the stimulation of the immunizing mechanism through

the absorption of the products of the tissue damage. (Colebrook, Eidenow and Hill. 13)

There is need for controlled clinical work in arthritis along the lines of light treatment; we feel inclined to recommend the use of predominantly ultra-violet irradiation from the standard mercury vapor or cold quartz lamp in the rheumatoid type of arthritis; and in the osteoarthritic type of arthritis the additional thermal effect from a carbon arc lamp appears to be more desirable.

3. Exercise. General exercise in the form of physical training or suitable athletic sports is of considerable importance in the harmonious upkeep of the vital forces of the body and in counteracting a general body inactivity towards which so many arthritics incline. Medical gymnastics or postural exercises on the other hand are indispensable for correcting faulty body mechanics, malposture, ptosis, imperfect action of the diaphragm, etc. To carry out these measures in actual practice requires an appreciation of the subject of exercise and a definite knowledge of basic orthopedic principles.

Exercise of the abdominal muscles by voluntary work or by low tension wave currents (the surging faradic or interrupted sinusoidal) has its object the improvement of tone of the musculature, the stimulation of peristalsis, the aiding of the venous return from the abdomen to the heart and the stimulation of glandular function. This is expected to result in the general improvement of circulation, digestion and elimination and to bring about a better functional efficiency of the entire body.

4. Massage. General body massage, as a rule, preceded by a general thermal measure is of recognized value for overcoming the feeling of fatigue, building up the muscular system, stimulating body metabolism and soothing the nervous system. In many of the health resorts the combination of general heating and massage with hydrotherapeutic procedures, such as the Aix le Bain douche are found beneficial in properly selected cases. Massage, local as well as general in arthritis must begin in the form of gentle stroking over a limited area and be increased in extent and force only as the patient becomes accustomed to the procedure.

5. Colonic irrigations. Colonic irrigations, like various other physical methods, have been popularized in recent years by commercial methods rather than by sound clinical considerations. As many physicians consider the intestinal tract as a major secondary focus of infection, is appears desirable that the bowels be kept open adequately without irritation. Whether colonic irrigations are necessary for this purpose or not depends on the circumstances of the individual case and the clinical experience of the attending physician.

B. Local Physical Measures

1. Heat. Local heat treatment has as its object the increase of local blood and lymph circulation and local tissue metabolism, promotion of resorption and restoration of function. An even more important effect of suitable local thermal application is that of the relief of pain, the symptom which is the most bothersome and most depressing, next to the stiffness and limitation of motion.

The measures available for local heating are also numerous. Hot wet compresses, hot poultices, electric heating pads are popular as pain relieving measures. For simple yet efficient routine heat application in the home and in the office, infra-red and luminous heat generators mounted on suitable stands are now universally preferred, and have largly replaced the former cumbersome dry baking apparatus and light boxes. penetrating effect of the luminous heat is somewhat deeper than that of infra-red generators. For home treatments patients should be instructed to use these appliances for half an hour two or three times a day over the affected joints. Well planned home treatment help to keep patients comfortable and allow the bridging of the time between office visits.

Diathermy has become recognized in recent years as the most efficient form of deep heating. Recent research work (Edstrom¹³) has proven without doubt that the interior of joints can be effectively heated. Extended clinical experience has shown that diathermy will do more for local relief of pain, promotion of resorption and restoration of function than any other physical measure; it also lends itself easily to a combination with other local and general measures. Best results can be expected in cases of osteoarthritis localized in one or two of the larger joints or in the spine. (Kovacs, R.14) In the so frequent bilateral knee involvement of the osteoarthritic type diathermy is well-nigh specific in its local sedative and restorative effect.

The monoterminal high frequency current (known as the Oudin current) has a well defined use for mild counter-irritation in fairly sub-acute arthritis involving several joints, it should be employed following external heat treatment. In painful involvement of small finger joints the hot air douche, from an ordinary hot air drier, affords usually a marked analgesic and resorptive effect.

2. The galvanic current is indicated in cases of atrophic arthritis of long standing where fibrous tissue changes have taken place. It is important that as large amount of current as can be borne be applied for a sufficiently long time. When there appears a combination of chronic arthritis and neuritic pain in the same extremity the local galvanic bath may be beneficial. Recent favorable reports from abroad on the effects of histamin ionization have been partly corroborated in this country.

3. Massage and exercise belong among the mechanical measures which are indispensable in almost every case of chronic arthritis, the others being active and passive exercise, low tension wave currents, and the static wave current. The common object of all these measures is (a) the maintenance and improvement of circulation and drainage in and around the affected joint, (b) the correction of the atrophy of the soft structures, especially those of the muscles.

Massage is the most readily available mechanical measure in arthritis. It must be applied in the most gentle and careful manner for its incorrect or over-zealous employment adds insult to injury by traumatizing the joints. As to massage, only gentle stroking with some light kneading should be performed, and this is better done in the neighborhood of the diseased joints rather than immediately over them. When the help of a skilled technician is not available, physicians should give suitable instruction for massage to family members of patients confined to the home; this will enable the patient to receive at least some massage with a measure of success.

In arthritis of the rheumatoid type motion must be insisted on if fibrous and later bony ankylosis is to be prevented, and the safest way of carrying this out is to have the patient do action exercises within the fullest possible range of motion after the parts have been limbered up by heat and massage. The passive movement of joints in conjunction with massage requires great caution; in many instances forced passive movements, twisting and bending tend to traumatize the tender joints. Patients must receive individualized instruction as to what exercises they can do at home and as to the range of motion they should attempt to attain.

The application of any mechanical measure should always be preceded by heat, external or deep, for it opens up vascular channels, relaxes the parts and enlarges the range of motion. Experience in therapeutic pools has shown that joints in the stage of sub-acute arthritis can be carried painlessly through a surprisingly large degree of motion.

4. The static wave current offers unexcelled benefit through gentle, pleasant molecular massage and decongestive effect, which is well recognized by those who have had actual experience with it. Wherever there is edema and marked stasis, the static wave current will reduce it evenly and with less effort and trauma than hand massage. Static sparks applied around tense and spastic joints aid their mobilizing; arthritis patients usually feel markedly limbered up after a series of well placed sparks.

5. Low tention wave currents, such as the surging faradic, the slow or interrupted sinusoidal, serve for maintaining the tone of muscles and preventing atrophies so frequent in the later

stages of chronic arthritis 15 The combination of voluntary exercise with electrical muscle stimulation tends to prevent one of the most frequent causes of increasing disability in arthritics, muscular atrophy

Conclusions

1 Chronic arthritis must be considered as a systemic disease with local inmifestations in the The different forms of arthritis are in close connection with the different constitutional The combatting of the disease is body types planned primarily through systemic measures to which local measures are added in accordance with the prevailing signs and symptoms

2 Constitutional therapy is directed toward the elimination of the arthritic diathesis, and towards the restoration of the full body vitality. It should be planned and carried out according to the different constitutional types

3 Physical measures are an invaluable aid in constitutional therapy and are the mainstay of They must be employed conthe local therapy sistently according to a definite plan, and this should provide for a suitable alternation of sys temie and local measures Polypragmicy is to be avoided but a certain change of methods is desirable in account of the so definitely chronic condition In some cases simple routine measures

may be applied in the home

DISCUSSION

R G Snyder, M D, New York City-I wish to compliment Dr Kovacs upon the splendid presentation of his subject. He has not limited his paper to a discussion of physiotherapy in chronic arthritis but has developed in his thesis all phases related to the subject

Dr Kovacs attempts to divide chronic arthritis cases into two distinct types. In my opinion a relatively small proportion of cases can be thus classified From my personal experience based on observations of ambulatory clinic and private practice patients, I would say that ap proximately twenty five per cent of the cases could be classed as belonging to the purely rheumatoid group and about ten or fifteen per cent as belonging to the purely osteoarthritic group The remaining sixty or sixty-five per cent of cases defy such rigid classification because they give evidence of infective as well as of metabolic or degenerative etiologic factors. The majority of cases, therefore, must be classed as belonging to the mixed type

Dr Kovacs' effort to classify the arthritie patient on the basis of constitutional make-up is

Here he has justly stressed the a worthy one point that even on that basis, only a small percentage of patients present the pure asthenic or pure plethoric habitus. Most individuals show distinct evidence of both types of physical development

In some quarters, the significance of focal infection in chronic arthritis is still in dispute. The failure to cure the patient after discovery and elimination of an obvious focus of infection is In the first place, often due to two factors elimination of the local focus of infection may not be sufficient unless diligent care is taken to treat the patient as a whole including local care of the affected joints Secondly, one is apt to forget that the finding and eradication of an obvious focus does not always result in the cure of the patient unless other concomitant foci are discovered and cleared up. In my experience, a clinical cure of the patient has often been made possible only after very diligent search and discovery of obscure and asymptomatic foci of infec tion in the tonsils, teeth, sinuses, genital and intestinal tracts

With further reference to the intestinal tract, one must emphasize the point that absorption of toxic putrefactive products from the intestine is another very important factor in chronic arthritis. Many arthritics on account of the associated pain are forced to curtail their physical activities to a very large extent. These patients usually suffer from chronic constipation, which must be given serious consideration in the general treatment of the case. Various methods of relieving the obstipation may be employed. My own practice has been to regulate the patient's diet, increase his fluid intake and limit or eliminate the use of cathartics. I also utilize abdominal massage and

body exercises and of colonic irrigations. I use both the long and short tube methods of colonic irrigation. In the arthritis clinic of the Hospital for the Ruptured and Crippled, the short tube is used. In my private practice, where the irrigations are given under my direct control by highly trained technicians, I employ the long fifty-four inch tube. To date, 16,470 irrigations have been given to 969 patients in private practice and 2,504 irrigations to 230 patients at the hospital clinic without any deleterious results that could be demonstrated either clinically, or proctoscopically or by augmented roentgenologic examination.

PRESENT DAY PROBLEMS IN LIGHT THERAPY

By FRANK HAMMOND KRUSEN, M.D., PHILADELPHIA, PA.

Read before the Session on Physical Therapy at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 6, 1933

IGHT therapy may be defined as the treatment of diseases by means of light rays (particularly invisible light rays). The commonly accepted view among physicians seems to be that we understand all about light therapy at present, and that we have little more to learn. As a matter of fact we are just on the threshold of knowledge concerning the physiological action of various light wave lengths concerning the sources of light rays and the methods of filtration of light rays. Most of us remember Sir Isaac Newton's demonstration of the splitting of a beam of sunlight by means of prism into the various colors, violet, indigo, blue, green, yellow, orange and red. Some of us remember that in 1800 Sir William Herschel found that there was an area beyond the red end of the visible spectrum that caused a thermometer to register a temperature even higher than in the red area, thus discovering that there were invisible heat rays which, because of their position below the red rays, were called infrared rays. Some of us remember that in 1801 Johann Ritter found that there were rays beyond the violet end of the visible spectrum which darkened silver chloride and thus discovered the invisible chemical rays which because of their position above the violet end of the spectrum were called ultraviolet rays. Most physicians believe that if they have a lamp which is labelled an infrared lamp, that it will produce rays from the infrared region which have some mysterious deeply penetrating heating property. And many physicians seem to believe that if they possess a lamp which is labelled an ultraviolet or sun lamp, that it will produce simply ultraviolet rays and that these rays will accomplish practically any desired anti-rachitic or bactericidal effect which they require. As a

matter of fact, on more careful study of the various light sources, it is found that these sources vary widely in the portions of the light spectrum which they produce and that it is essential to have certain portions, of the light spectrum, in proper intensity reproduced by the source in order to obtain the desired physiological effect.

To practice light therapy intelligently the physician should be acquainted with the physical properties of the light which he is using. Humphris¹ has stated that, "perhaps the chief evil is the almost indiscriminate use of artificial sunlight by those who are insufficiently acquainted with its use, properties and dan-

gers."

The commonly accepted unit for measurement for light wave lengths is the millimicron which equals one millionth of a millimeter. The wave length of visible light extends from 390 millimicrons at the violet end of the spectrum to 770 millimicrons at the red end. Beyond the violet light lie the ultraviolet rays which extend from 390 millimicrons down to 13.6 millimicrons. Beyond the red end of visible light lie the infrared rays which extend from 770 millimicrons up to 15,000 millimicrons.

The sources used for the production of light rays for therapeutic purposes must be heated to a very high temperature. The greater the temperature of the source, the shorter the wave length of the light rays. The temperature of boiling water is 100° centigrade, yet merely to produce the longer infrared rays it is necessary to heat the source to three or four times the temperature of boiling water, (i. e., 300 to 400 degrees centigrade). A source heated to this temperature will give off rays with the maximum emission from 4000 to 5000 millimi-

crons, whereas at low red heat (600 to 800 degrees centigrade) the maximum emission is from 2000 to 3000 millimicrons Heated eoils, plates or bars, the so called "infrared generators' are used to produce rays in this portion of the spectrum These rays which are in the far infrared do not penetrate deeply into the skin. If the source is heated to an even higher degree, as is the case with the tungsten filament lamp, the near infrared rays will be pro A tungsten filament lamp will give off rays ranging from 300 to 4500 millimicrons 'with a maximum emission ranging from 1100 to 2000 millimicrons "

Rays from a tungsten filament lamp though still not penetrating to very great depth will penetrate more deeply than rays from an infrared generator. This is a fact not commonly recognized A tungsten hlament light gives off both heat rays and visible light rays order to have the source emit rays in three ranges of the spectrum, that is, to give off heat rays, light rays and ultraviolet rays, it is necessary to heat it to even higher temperature (3000 degrees centigrade or lugher) Coblentz² points out that 'since solids (e.g., metals such as tungsten) evaporate very rapidly at high temperatures, sources of ultraviolet radiation are practically confined to electric arcs between electrodes of metals, of carbon, and of mercury vapor in a closed tube of quartz glass called 'the burner'' One may possibly visualize the heating of a light source and the associated gradual decrease in the wave length of the light rays by thinking of an ordinary iron poker placed in the fire When the poker is first beginning to heat up if it is pulled from the fire, it will be found to remain black but still give off heat rays when held close to the hand These are the far infrared rays. If the poker is again placed in the fire and becomes still hotter it will glow to a dull red heat. If examined at this time it will be found to be give ing off rays in the middle portion of the in-If heated still more it will frared spectrum be found to turn yellow at which time it will be giving off near infrared rays and also visible light from the red and yellow end of the spee-If heated still more it will become trum white hot In other words it will be giving off white light or rays throughout the entire visible spectrum as well as heat rays. It would be impossible to heat a poker hot enough to have it give off ultraviolet rays because as Coblentz points out it would evaporate before it reached the necessary temperature

There is a common misconception that light rays penetrate to great depth. The far infrared rays as a matter of fact penetrate to a depth of about 1 centimeter while the near infrared rays which are the most penetrating of all light

rays penetrate only to a depth of about 15 centimeters (three fifths of an inch)3, while the ultraviolet rays are still less penetrating reaching to a depth of probably not more than 1 millimeter 4 Mayers points out that "penetration should not be stressed as the factor for the interpretation of physiologic effects" of light

Sources of Therapeutic Light *

1 The sun at high altitude gives off rays froin 290 to 4000 millimicrons with greatest intensity at about 490 millimicrons. The sun at sea level gives off rays froin 300 of a very faint intensity up to 350, then a rapid rise to 490 and a gradual fall to 4000 millimicrons. The atmosphere filters out much of the short ultraviolet rays found at higher altitude.

2 The quartz mercury vapor are gives off a series of intense spectral lines (namely, at 257, 265, 297, 302, 313, 334 and 365 millimicrons) superimposed on a faint continuous spectrum 'About six per cent of the total radiation contitted is of wave lengths shorter than 290 millimicrons which are entirely absent in sunlight. They have a high germicidal action"

3 Carbon ares

(a) The white flame are gives off radiation from 220 millimicrons to more than 4000 millimicrons with a strong emission in the violet at 389 millimicrons. This is the nearest unscreened artificial source to sunlight but is still

far from being an exact match

(b) White flame are through special (Corex D) glass screen. The glass shuts out the short ultraviolet beyond 290 millimierons and the infrared rays longer than 4000 millimierons. This screen puts the light within the same spectral limits as sunlight but the intense band (known as the evanogen band) at 389 millimierons remains. This is the closest artificial source to sunlight but even this is not an evact match.

(e) Neutral core carbon are from these carbons the radiation of wave lengths less than 320 millimicrons is very weak, the radiation being concentrated almost entirely in the so called "eyanogen band" at 389 millimicrons

(d) The blue flame carbon are gives off rays from 220 to more than 4000 millimerons. The ultraviolet radiation of wave lengths less than 310 millimierons exceeds that of all other carbon arcs.

(e) Yellow flame carbon are gives off rays from 220 to more than 4000 millimierons but has an intense band from 290 to 320 millimierons and also a strong emission from 500 to 750 millimierons

(f) The red flame earbon are has the same spectral limits as the previous earbon are mentioned but is conspicuous for its intense emis-

sion between 550 and 750 millimicrons in the orange-red portion of the spectrum.

- 4. Tungsten and Nickel arcs give off numerous fine lines extending from 220 to 750 millimicrons. There are strong lines especially at 230 and 350 millimicrons.
- 5. "Cold Quartz" Ultraviolet Lamps give off a series of spectral lines at 254, 297, and 313 millimicrons. The most intense emission is at 254 millimicrons. These rays are predominatingly of wave lengths which possess a high germicidal action but which destroy vitamin-D.
- 6. Heat coils, plates and bars (so-called "infrared generators"). These give off perceptible radiation of all wave lengths throughout the infrared to 1500 millimicrons. The maximum emission varies according to the surface temperature of the "generator." At a surface temperature of 300 to 400 degrees centigrade the maximum emission is from 4000 to 5000 millimicrons, while at a temperature of 600 to 800 degrees centigrade the maximum emission is from 2000 to 3000 millimicrons. These rays do not penetrate deeply into the skin.
- 7. Tungsten filament lamps give off rays from 300 to 4500 millimicrons with a maximum emission from 1100 to 2000 millimicrons. About thirty per cent. of the rays are in the region from 770 to 1200 millimicrons in the near infrared which rays do penetrate to the greatest depth into the skin.
- 8. S-1 and S-2 Ultraviolet Lamps. These rather new lamps give off a series of strong emission lines (namely at 280, 297, 302, 313, 334, 365 and 405 millimicrons) superimposed on a continuous spectrum. The improved S-1 lamp at a distance of three feet gives off radiation which is about equal to noon June sunlight.

9. The induced ultraviolet glow lamp. This newest type of lamp gives off a series of intense spectral lines (namely at 254, 265, 280, 297, 313, 365, 436 and 546 millimicrons). The most intense lines are at 365 and 436 while there is a fairly intense line at 313 millimicrons.

When one considers the marked variation in the spectral limits and the intensity of the radiation from the different sources just mentioned, he realizes that the use of lights for the treatment of disease is not the simple matter that it might at first be considered. One soon finds that it is of great practical importance to become familiar with the radiation from the lamp he is using for the therapeutic application of light therapy. For instance, the "cold-quartz ultraviolet lamp" produces a very intense band of rays at 254 millimicrons in the short ultraviolet. These rays destroy vitamin-D but are bactericidal and cytocidal. Therefore

rays from such a source are probably of value for their germicidal effect but contraindicated as an antirachitic agent. Likewise, the usual quartz mercury vapor arc produces six per cent, of its rays in wave lengths shorter than 290 millimicrons in this same germicidal vitamin-D destroying area. It is therefore desirable that these short ultraviolet rays be screened out by means of a proper filter if such a lamp is to be used for its maximum antirachitic effect. This is a fact not commonly recognized and one which should be given more consideration. Again, the tungsten filament lamp produces intense radiation (about thirty per cent. of its total rays) in that portion of the infrared (770 to 1200 millimicrons) which penetrates to the blood bearing or capillary area of the skin; whereas the so-called "infrared generators" produce no such intensity of penetrating rays, but do produce more long wave length infrared rays which cause counterirritation. The luminous heater (tungsten filament lamp), therefore, should be used when it is desired to increase local circulation; and the "infrared generators" should be used for surface counterirritation. This fact also is not commonly recognized.

Time will not permit a complete discussion of all the problems which at present are facing physicians who desire to practice light therapy in a logical manner, however, the simple discussion of the various light sources presented here will. I hope, stimulate more interest in the careful selection of light sources.

TECHNIQUE OF APPLICATION OF LIGHT RAYS:

In addition to knowing the light source which he is using, the physician should also know two simple laws which govern the application of light rays. First of these is known as the inverse square law. This law states that the intensity of radiation from any light source varies inversely with the square of the distance from the source. For example: the usual distance between an air-cooled quartz lamp burner and the patient is 36 inches. Applying this law, if the distance is cut in half (to 18 inches) the intensity will not be twice as great as one would at first expect, but four times as great. If the distance is decreased to onethird, the intensity becomes nine times greater. It is necessary to remember this law if one is to prevent overdosage when shortening the distance between the light source and the The other law is known as the Cosine law which states that the energy per square centimeter is proportional to a constant times the Cosine of the angle made by a line connecting the source and the patient and the line perpendicular to the patient's body. That constant is the light per square centimeter

when the patient is perpendicular to the line joining the light and the patient. In simple words this law states that light rays are most intense when the part to be irradiated is at right angles to a line joining the patient and the light source and that there is a gradual diminution in intensity as the patient becomes more oblique to this line. At an inclination of 30 degrees (one third of a right angle), twice the exposure is necessary to produce the same radiation as at ninety degrees (a right angle). This law may be visualized by imagining the face of a clock and picturing the patient as being at the center of the clock face with the light source at 12 o'clock. In this position the light rays will be at right angles to the patient and the greatest intensity of the radiation will be obtained. If now the light source is moved either to one o'clock or to eleven o'clock, the rays will fall upon the patient at an inclined angle and there will be only 80 per cent. of the maximum intensity. Again, if the light source is moved to either ten o'clock or to two o'clock the inclination of the rays will be even greater and only 40 per cent. of the maximum intensity of the radiation will be obtained. This law should be remembered since it indicates that to obtain the maximum intensity from a light source the part to be treated should be at right angles to a line joining this part and the light source.

Conclusions:

A study of the subject of light therapy leads to the following conclusions concerning it.

"1. Despite general usage of sunlight therapy, and of various types of therapeutic light, light therapy is still in a chaotic state.

2. There is still much controversy concerning the physiological effects of various light wave lengths, and about the technique of application.

3. Light therapy has been applied too frequently in an empirical manner, without suf-

ficient knowledge of its effects.

4. The different sources of light vary greatly in extent and intensity of their radiation. Knowledge of these variations is essential for intelligent application of the rays.

5. There is a need for more accurate selec-

tion of therapeutic rays.

6. Knowledge of the mechanism of the source and of one or two simple laws, is

essential for correct therapeutic use of light

7. Dosage of light has not yet been standardized, and there are marked differences of opinion as to proper dosage.

8. There are numerous forms of administra-

tion of light rays.

9. Light therapy (especially ultraviolet therapy) has been recommended in an absurdly

large number of conditions.

10. Ultraviolet therapy is indicated in a fairly large number of conditions, and it has an almost specific action in rickets, tetany, spasmophilia, and, when properly applied, in lupus vulgaris. It is a valuable adjunct in the treatment of selected cases of tuberculosis, and in minor degrees of calcium and phosphorus deficiency, as well as in anemia. It has a valuable, but distinctly limited field of usefulness, in skin diseases. It will impart an antiraelitie power to the milk of an irradiated mother, or of an irradiated cow, or to directly irradiated milk. Locally it is probably of value for its superficial bactericidal and cytocidal effects upon indolent and infected wounds and chronic uleers. It will also improve the tone of unused muscles. It may be used to impart an antirachitic potency to foods and drugs, and also it may be applied to the skin as an adjunct to the administration of such foods and drugs.

11. Infrared therapy is especially indicated in nephritis, arthritis, circulatory diseases, neurologie conditions, fractures, dislocations,

and sprains.

12. Light therapy has distinct limitations and dangers with which its users should be

13. The millennium in light therapy will not be reached until we have gained more accurate knowledge of the exact action of various wave lengths, and until we know how to produce limited ranges of wave lengths in proper doses. (This will probably be accomplished by modification of the sources and by more accurate filteration of the rays.)

14. Even with our present rather limited and chaotic understanding of light therapy, it may be said to be distinctly valuable in a fairly large number of pathological conditions, and to offer great promise when more accurate methods of administration are developed, and when we have attained more knowledge of therapeutic action of various wave lengths."

DOMINANT PROBLEMS IN THE PRACTICE OF MEDICINE

The resumption of medical meetings after the Summer's vacation brings out the dominant problems with which physicians have to deal. These problems fall naturally into two groups:

- 1. Those of the individual doctor dealing with the individual patient. These concern scientific medicine.
- 2. Those of the medical profession as an im-

personal group giving medical care to the These concern administrative medicine

Administrative medicine consists largely in preparing the people as a group to extend the scope of medical services along two lines

I In the prevention of disease when there is

no visible threat to an individual

2 In making provision for medical service to those who are financially unable to purchase it for themselves

The modern system of administrative medicine began with health departments only about a quarter of a century ago, and was fostered by lay or ganizations that were heavily endowed with the means of educating the people and of financing demonstrations of the efficiency of the newer methods of health service. A dominant problem that grew naturally out of these educational campaigns was the establishment of the county as the administrative unit of public health work county licalth department was one of the greater problems that were discussed in the medical societics of the counties, the states, and the nation five years ago. The problem is still far from be ing settled, but out of the discussion there has come the accepted conclusion that the county health department is desirable and practical in certain counties, and much less so in others

The discussions also led to the development of the principle that the county medical society is the natural organization that shall determine the adoption of a new method of the administration of medical services. This principle is illustrated by the establishment of county health departments in those New York State countres in which the medical societies developed and supported plans which were adapted to their particular counties, and by the failure to apply a blanket form of nrganization not fitted and adjusted to the individual New York State recognizes the principle of local determination of health policies by its laws based on permission in distinction from

mandation

The operation of the ancient economic law that services cost money led the great health organizations to undertake a survey of the costs of medical care the most important one being that by a national committee which conducted investigations over a period of five years and made its final report on November 29 1932 (See the New York STATE JOURNAL OF MEDICINE, Dec 15, 1932 page 1432) A leading recommendation of the committee was the adoption of the principle of health insurance especially its voluntary forms The immediate object of health insurance is to provide a fund by which the insured sick person can secure medical treatment. The report of the committee has ever since been a leading subject of discussion in the incdical journals of the sev

eral state societies, and in their meetings, the general conclusion being that a county society may

adopt a plan of its own derising

New York State, in 1929, had anticipated the adoption of this principle by enacting the Welfare Law which was mandatory in its provision that the local welfare officials should provide medical service for those who otherwise could not obtain it, but the law was permissive in its administrative provisions, leaving the county to determine whether to continue the ancient system of an overseer of the poor in each township or to centralize all relief in a county commissioner, and also leaving in the lay officials the decision whether or not to give the service to any particular individual, and how much to pay the doctor for his services. Some county medical societies in New York State had taken definite action and assumed the leadership by seeking consultations with the welfare officials, and making agreements regarding authorizations for treating the sick and the fees to be paid. It was a revolutionary idea that the doctor should be paid by the community for treating the sick poor, and the physicians in only a few counties had been able to develop administrative systems that were satisfactory to the doctors and the officials However, the participation of both the Federal and the State governments in the relief system is compelling the physicians in each county to devise new principles and rules that shall control their relations to the welfare officers

The problem of the relation of physicians to welfare officials is the dominant topic of discussinn today in every medical society. The decision lies with each county society. The officers of the State Society will always be ready to give advice, but the fitting and adaptation of the system to the local officials must necessarily be the work of the local physicians acting through the county medical societies

There is abundant common ground on which physicians and welfare officials can meet is a mutual recognition of the need for the medical service, of the willingness of the physicians to give it, and of the intent of the law that the community shall provide it. The principal prob lem that is left is that of giving authorization for the service and of paying the doctor for it. An agreement can always he reached when one party has what the other must have, and the second party has the means to pay for it

The dominance and acuteness of the present economic problem does not indicate that physicians are neglecting those problems which for merly received their major consideration solution of one difficult problem develops a habit and capacity of meeting conditions as they arise, and points a way by which other problems may be solved

MEDICAL PROGRESS

The Indications for Evipan-Sodium Anesthesia.—Eugen Kobel says that for brief operaations, not requiring more than 10-15 minutes, evipan-sodium offers the ideal form of general The patient sinks comfortably anesthesia. into a quiet sleep without any of the preliminary disagreeable sensations attendant upon the use of most general anesthetics. Its use should, however, be limited to interventions performed within hospital walls, since in a few cases a period of violent unrest has followed the narcosis after the lapse of 15 or more minutes. Among Kobel's first ten cases there were four which presented intermediate states that required forcible restraint To determine the time limits within which anesthesia is complete, a breast amputation and a total vaginal extirpation were carried out, 10 c.c. evipansodium being injected intravenously in each case. In the breast amputation, which required 35 minutes, the patient remained perfectly quiet for 22 minutes, after which violent struggling began that proved a serious handicap to the surgeon, although the patient suffered no pain and had no memory of it afterward. The motor excitation concerned chiefly the leg muscles. No other anesthetic was given, and the operation was successfully concluded despite the hindrance offered. In the vaginal operation the struggling began after 35 minutes, and continued during the 50 minutes of the procedure. In this case too there was no memory of the unrest, which lasted two hours after the end of the operation. An hour and a half later the patient awoke from a peaceful sleep, in excellent condition and unaware of having struggled. One patient who underwent an excision from the portio had double vision upon awaking; after further sleep, she awoke with normal vision, and with no memory of the operation, but full memory of the double vision. Such cases as these make it evident that with patients who are psychically labile, and who present a ready excitability of the central nervous system care should be taken not to prolong the operation unduly nor undertake the administration of evipan-sodium in office practice. As a basis for the introduction of ether this new anesthetic is ideal, but it should not be given with a view to saving ether, since it is impossible at the present time to know just when its exciting action will set in. One should not administer it for more than 5 to 8 minutes before beginning the ether narcosis; when given in this way, it relieves the patient from all the unpleasent subjective feelings that the second form of anesthesia might produce. When used alone, it is especially indicated in dislocations, care of fractures, opening of abscesses, furuncles and felons, nail extractions, examination requiring an anesthetic, and so forth. — Deutsche medizinische Wochenschrift, June 30, 1933.

Angina Pectoris, Spasmodic or Paroxysmal.—John Hay, writing in the Practitioner, June, 1933, cxxx, 6, says that two factors clearly involved in anginal pain are the amount of work performed by the heart and the quantity of blood flowing through the coronaries. If the work exceeds the supply there is a relative ischemia and pain. Another factor is the glycogen metabolism of the myocardium and the occurrence of nutritional disorders. The essential characteristic of spasmodic angina is that the substernal discomfort or pain is increased in response to effort and is relieved by rest. When the pain is over the lower third of the sternum or xiphisternum it is often labelled "indigestion." In spasmodic angina the average expectation of life, excluding cases of coronary thrombosis, is about five or six years, though some patients far outlive this. A steady diminution in the amount of effort required to bring on pain is an index of depreciation. In the treatment of an attack, if the pain increases in spite of rest, one or more tablets of trinitrite should be chewed slowly; if these yield no relief, the inhalation of amyl nitrite is essential. If the vasodilators fail and the pain is intense, there is no drug comparable to morphine. Less severe attacks of flatulency are generally relieved by brandy or a strong carminative draught such as menthol 8 grains, spirits of ammonia, tincture of carduus compound, and tincture of ginger compound, of each 1 ounce. A mixture containing opium and chloral, given twice daily, undoubtedly diminishes the tendency to anginal attacks. Haste and hurry after a meal, particularly breakfast, should be avoided. In the general treatment reliance must be placed on a change of life rather than on drugs. A more leisurely life is the aim, but a life in which all vital interests are retained. Exercise is advisable as the heart muscle must be kept fit, one. of the best forms being walking. Meals should be small, the food simple and digestible. In those in whom there is an outstanding mental factor massive doses of ammonium bromide are undoubtedly helpful, 20 grains two or three

times daily, with the addition of 10 grains of chloral hydrate twice daily. Later luminal, ½ grain, and theominal, 5 grains, may be administered once or twice daily with advantage. Occasionally diathermy diminishes the number and severity of the attacks. It is best administered with one electrode placed over the sternum and the other between the shoulders. A suitable dose is from 800 to 1,500 milliamperes for 20 to 30 minutes two or three times a week. Shirley Smith recommends insulin and glucose in anginal patients, irrespective of the presence or absence of diabetes.

Chloride Disequilibrium in Operative Shock. -F. Legueu, B. Fey, Palazzoli, and Mile. Lebert, writing in the Bulletin de l'Académie de Médecine of June 27, 1933, say that their studies have convinced them that chloride disequilibrium is one of the main factors in operative and traumatic shock, and that excess of chlorides in the tissues is at the root of the decrease in blood chlorides observed under conditions of shock. The hypochloremia following operation is more or less pronounced; it lasts 3-4 days ordinarily, after which the chloride content of the blood rises to normal, provided serious accidents do not occur to prevent it. It is nearly always associated with a certain degree of uremia, for which it seems to be responsible. While vomiting, diarrhea, and profuse sweating might explain it occasionally, it is present also in certain cases in which none of these phenomena has been observed. Another striking fact is that the urinary chlorides too are dimished in operative shock, falling to 2 gm., 1 gm., or even 0.50 gm. per liter; and this diminution is still evident 8-10 days after operation. It outlasts the phase of hypochloremia and is the more grave in that it coincides with a marked oliguria. Thus we observe the paradox of a diminution of ehlorides in the blood and in the urine at the same time, showing that the organism is not eliminating its chlorides. If these salts are in neither the blood nor the urine, where are they? In animals artificially traumatized and then killed on the 2nd, 3rd, or 4th day, the authors demonstrated that the ehlorine is fixed in the organ traumatized, where its quantity is found to exceed that of the symmetrical organ, being generally more than double the latter. In one case the quantity exceeded even the amount of blood ehloride that had been present before the traumatism. This excess in the tissues is purely local, and corresponds exclusively to the traumatic focus. It is almost immediate, being found after a few hours, and is still present after 18 days; it then disappears, too gradually to permit of a graph being made. Its degree is proportional to the importance of the traumatism.

In traumatic shock following severe muscle contusion, a tissue chloride content amounting to 4 gm. was observed, confirming the authors' researches, which had been pursued for a period of six months. If it is not possible to prevent the chlorides from being called into the tissues, it is at least possible to reestablish the lost balance by the introduction of large amounts of chloride into the bodily economy and thus to put the patient on the road to health.

A Room-Sized Respirator.—Philip Drinker and James L. Wilson describe the construction and use of a respirator which is so large that several patients can be treated at the same time and into which nurses and physicians can comfortably enter to care for the patient. With the usual type of respirator ordinary nursing care is exceedingly difficult, and no dependable physical examination, especially of the heart and lungs, can be made. It is also evident that in a severe epidemic of poliomyelitis, even with a large number of respirators available, only the most serious cases could be treated and those for periods just long enough to tide them over the most severe stage of their illness. For these reasons, as well as for the economic advantages of group treatment of paralyzed patients, the authors were stimulated in their effort to develop the "respirator room." This is built of steel plates, and is so constructed that four patients, in double tiers, can be cared for. The size of the machine can be varied without affecting materially the cost either of construction or of operation. The room is provided with a number of small windows to allow unobstructed view of the patients' bodies from the outside and of the patients' heads from the inside. Communication between persons inside and those outside the room can be made without raising the voice. The patient receives the same sort of nursing and medical care as he would in a hospital bed. Any desired combination of pressures and breathing rates is obtainable by a blower and valve arrangement. The blower is driven by a five-horse power motor, and is a standard type of unit used widely in industry; it is installed in the basement with various other mechanical equipments of the building. Patients can be placed in the respirator room with greater speed than in the small ma-There is no difficulty in maintaining respiratory rates varying from 10 per minute to 50, and at any pressure up to 35 cm.

The authors point out that, so far as theory

The authors point out that, so far as theory and clinical observation can be relied upon, the greatest recovery of paralysis takes place if the museles are given maximum rest, so that a patient with respiratory paralysis due to poliomyelitis, should be given aid with the respirator as early, as continuously, and for as long a time

as is possible. Patients with only partial paralysis of the respiratory muscles, who can still breathe sufficiently well to carry on pulmonary ventilation adequately, probably benefit considerably by the rest that treatment in a respirator gives them.—New England Journal of Medicine, August 3, 1933, ccix, 5.

Observations on Lichen Urticatus.—Hugh Gordon, writing in The Lancet, July 15, 1933, ccxxv, 5733, states that while lichen urticatus is one of the commoner skin diseases of children, occasional difficulty in the differential diagnosis of scabies may arise, particularly where the lichen urticatus papules become secondarily in-Borderline cases may resemble the prurigo of Hebra. Possibly the two conditions are simply variants. Urticaria as seen in the adult is rarely met with in children, but in both adults and children the conditions are examples of the skin response which is exactly reproduced experimentally by the action of histamine, and which fall into the group of allergic phenomena. Lichen urticatus has usually been regarded as due to some dietary indiscretion. There are reasons, however, for supposing that the alimentary factor is by no means solely responsible. One factor named by all investigators is heat, the condition being more common in the summer months. In a review of 50 cases during the past year the author has been impressed by the possibility of a nervous factor in many cases; 50 per cent of the children in this group were of decidedly nervous temperament. Changes of habitat seemed in some cases to bring on attacks. The exanthemata figured as a very real predisposing factor in ten cases. In 10 per cent the first attack was said to have followed an accident or shock. In the treatment of the cases four patients were admitted to the hospital; these all rapidly improved, fresh lesions ceasing to appear soon after admission. All patients received a bromide mixture containing 1 to 2 grains of ammonium bromide for each year of life, given three times a day, with the use of a calamine and phenol lotion. This treatment gave unexpectedly good results, though it could not be claimed that all patients were rapidly cured. As an adjuvant in some cases, particularly in pale and debilitated children, general carbon-arc baths appeared to be of great value. The results of the bromide treatment were definitely better than those obtained with other drugs. That a skin lesion in a child said to be "nervous" should improve upon the administration of bromide is obviously very slender proof that such a condition should be considered a "dermatological The observations presented in this paper suggest, however, that in some cases a psychological factor, in the widest sense of the term, may play a greater part than has usually been admitted.

A New Treatment for Chronic Arthritis of the Hip; Forage of the Epiphysis of the Femur.—In the Acta medica scandinavia of June 27, 1933, Jacques Graber-Duvernay says that he has employed Louis Duvernay's forage of the epiphysis of the femur in 13 cases of chronic arthritis of the hip. The center of the head of the femur is first found by means of fluoroscopy or radiography. Under careful local anesthesia no difficulty is encountered in reaching the external aspect of the femur through an incision 8-10 cm. long. The crest which forms the lower limit of the great trochanter is easily rcognizd by the finger. At a point 1 cm. below this, and halfway between the anterior and posterior aspects of the femur a gimlet 6 mm. in diameter and 12-18 cm. long is made to penetrate the bone in the direction of the head. When the instrument enters the spongy tissues the patient feels a sharp pain, which may be attenuated by a preliminary injection of a few drops of novocaine. The gimlet must be driven directly into the head of the femur, as nearly as possible into its cen-The nearer the center it passes, the more pronounced will be the modifications of the circulation which condition the good result. After the forage, a splinter of dead bone 5-7 cm. long and 5 cm. in diameter may be inserted in the opening, though this is not indispensable, its chief value being that it serves as a means of orientation for the correctness of the direction. when the postoperative radiogram, which is of capital importance, is taken. In its absence. lipiodol may be used for the same purpose, being injected through the trapanation orifice. Within 3 days, with impressive regularity, the pain disappears or is at least greatly ameliorated in nearly every case, only the line of incision being still sensitive. This improvement has been maintained to date, over 18 months in the author's earliest cases. A gonalgia appears on the 2nd day after operation, which disappears after 6-8 The patients can begin to walk on the 12th to 15th day. The action exerted by forage upon the lesions is explained as follows: It is well known that these lesions, consisting of rarefaction of the bone and of osteophytic proliferation, are due to a phenomenon of a vasomotor order: a hyperemia which causes a process of osteolysis and a local calcium mutation. Forage produces vasomotor modifications of the circulation which can be studied by the oscillometer. The new element that it introduces appears to be a lowering of the oscillometric index of the side operated on, in the month following operation. But all traumatism (and the operative act is such) causes a hyperemia, revealed by increasing the oscillometric index. It therefore appears logical to assume that during the first weeks following operation a vascular disequilibrium is produced that results in hyperemia, but that at the end of that time the vasomotor equilibrium is reestablished in the direction of a rarefaction of the blood that is, a vasoconstriction, or an arrest of the evolution of the pathological process

Perforation of the Stomach, The Sign of "Burning Drops Falling into the Abdominal Cavity "-Attention is drawn by Ed Juillard to a sign of gastric perforation which, so far as the author knows, has not been mentioned in It was described by a patient as the literature a horrible sensation of "burning drops falling into the abdominal cavity," or of "a jet of burning liquid being poured from a cruet into the howels" The patient in question, who had not exhibited the classic symptoms of perforation, was found at operation actually to have a perforation on the lesser curvature of the stomach There was excruciating pain localized not only in the region of the abdomen and liver but also in the back. If the author had attached to this expression of the patient's the importance that it deserved, the diagnosis might have been established immediately, before the appearance of a boardlike rigidity and other characteristic symptoms. As it was, the presence of intense pain over the gall bladder led to a tentative diagnosis When, 2-3 hours later, a genof cholclithnasis eral muscular rigidity was observed, giving the impression of a boardlike hardness to the entire abdomen, with pulse accelerated despite a normal temperature, the suspicion of a perforation was naturally aroused. The patient had not admitted a past history of a stomach affection, he had never had hematemesis, melena or pains after eating and it was not until after his operation that he mentioned that a small meal had often had a soothing effect upon cramps. The experience gained from this case has led the author to question other patients with reference to this symptom of a burning drop sensation, and has received enough affirmative answers to lead him to believe that the sign is pathognomonic of a perforated gastric or duodenal ulcer, the acid gastric juice passing through the perforation into the abdominal cavity, causing the patient a writhing agony at the point of incidence appears therefore to have an importance of the first rank for establishing a diagnosis of the beginning of perforation, when the classic signs may be entirely absent. Possibly it is less rare than might be supposed. It is reported in the behef that other physicians may on occasion elicit, by questioning the admission of a similar sensation from patients suffering with an undiagnosed abdominal condition, and may thus be led to suspect a gastric perforation-Schweizerische medizinische Wochenschrift, July 29, 1933

The Biochemistry of Asthmatic Conditions

—G H Oriel describes his investigations with
reference to irrinary proteose in asthmatic
patients He says it has become obvious that

asthmatic subjects are divisible from a biochemieal standpoint into two main groups (a) a true allergic group in which skin tests to foreign protems are positive, and (b) a group in which in positive skin tests are demonstrable. It has been slimwn that so-called proteose is present in normal urine. In the asthmatic the quantity varies from time to time, but is greatly increased during the In the present study Oriel has succeeded in the separation of normal proteose into one fraction, and of asthmatic proteose into three fractions, thus providing a method of distinguishing between the two substances. The three fractions isolated from an asthmatic during the attack and the proteose fraction from a normal person were severally tested on a series of protein sensitive astlimatics. In no case was a positive reaction obtained with the normal proteose Approximately the same results were obtained with each of the three fractions as with the whole proteose from the asthmatic individual. Oriel then attempted to ascertain which portion of the protein molecule was the one giving the skin test in subjects susceptible to egg. The work of Avery and Heidelberger suggested that it might be in the nature of a carbohydrate Using Rivington's method of isolating the carboly drate portion of serum albumin Oriel isolated a carbohydrate substance which chemically was glucosamine himan-This substance was found to be quite mert in hoth normal and egg-sensitive persons but it was noticed that the intermediate products of the alkaline Indrolysis of egg gave positive tests in It was therefore deteregg-sensitive persons nined to make intermediate products of digestion using trypsin. This substance gave negative reactions in normal subjects, while six egg-sensitive persons all gave positive reactions. It appears that, although the specificity of a protein probably depends on its carbohydrate moiety yet it is necessary for a linkage of aminoacids to be present before a positive skin test can he obtained This work suggested a new approach in the treatment of asthma Gradually increasing doses of proteose were given by subcutaneous injection to 70 asthmatic patients. The initial dose was a very small one, Ol cc of a dilution ten times weaker than the lowest dilution of autogenous urmary proteose which gives a positive skin test. and this was repeated at weekly intervals, increasing by 01 cc until there was a reaction or signs of improvement. Of 44 protein sensitive persons 23 per cent were rendered symptom-free 46 per cent were much improved, while in 8 per cent there was no change Of 26 nonproteinsensitive persons 8 per cent became symptomfree, 19 per cent were much improved, while in 54 per cent there was no change It seems that the protein sensitive asthmatic is much more likely to benefit from treatment with his urinary proteose than the nonprotein-sensitive asthmatic ---The Lancet, August 19, 1933, ccxv. 5738

LEGAL

MALPRACTICE—FOREIGN BODY

By Lorenz J. Brosnan, Esq.

Counsel, Medical Society of the State of New York.

It is always interesting to read cases decided in other States on the subject of malpractice. Especially is this true in cases where it is claimed that a foreign body was permitted to remain within the person of the patient by the operating surgeon. Not all jurisdictions in this country are in accord upon the legal situation presented in a case of this kind. A recent case involving a retained foreign body decided by the highest court of one of our Western States will, we believe, be of general interest to the profession.

A man had been suffering for two or three years from a condition of hernia, and made arrangements to be operated upon by a certain Dr. H, who was to be assisted by a Dr. E. The operation was performed on October 5th at a small private hospital. Subsequent thereto there was some drainage of pus, and on November 4th an abscess of the scrotum was incised by Dr. E. The wounds did not close until November 28th, and the patient remained in the hospital until the 13th of December.

Suit was brought against the two doctors charging them with negligence in leaving and permitting to remain inside the plaintiff's abdomen a piece of towel or surgical gauze. It was claimed that the said foreign substance caused an infection, which required the plaintiff to be long confined in the hospital, and as a result he claimed to have been disabled, in addition, after his discharge from the hospital. The defendants generally denied in their answer all charges of negligence.

When the case came up for trial, the principal witness whom the plaintiff called was a Mrs. M, who had been in charge of the hospital where the operation was performed. She was not a registered nurse, but had been for some years practicing as a trained nurse, looking after the patients in the hospital herself with some additional help. She testified that she had prepared the patient for operation, but that she was not present during. the operation and knew nothing about it. She said that she had been in daily attendance upon the patient postoperatively with the doctors, assisting with dressings and recording the progress, medicine, temperature and the like. She asserted that about ten days after the operation a "stitch abscess" developed, that

drainage of that abscess continued until October 22nd, when she claimed a retained sponge was removed. Mrs. M described the said occurrence and told that in the presence of Dr. E, she observed something foreign within the opening of the wound that looked like cloth and not like a sponge, and that she took a hemostat and pulled it out. She testified that it looked like a towel about a foot wide by two feet long, such a towel as are used as screens for operations. Her notation upon the record, however, was "Retained sponge removed." She stated that the piece of material that she had removed had been subsequently destroyed by her. She described in detail the daily record of the patient from that day down to the date of his discharge from the hos-On cross-examination she described the careful methods in use in her hospital for the sterilization of all materials to be used in the course of operations.

The plaintiff's examination of the defendant Dr. H. (which was permitted under the practice in that State as part of the plaintiff's case) elicited from the doctor the testimony that it is bad practice for a surgeon to leave a piece of towel within a wound. Dr. H. added, however, that a foreign substance, such as a towel, if sterile would not cause pus when left in a wound. Dr. E. stated on similar cross-examination that ordinarily, after an operation for hernia, without complications, a patient is able to leave the hospital within thirty days. The testimony of the defendants merely consisted of a re-direct examination which brought out their statement to the effect that no towel was left in the incision, but that gauze drainage had been left in the wound to protect against pus, and that the latter was good practice.

No other medical testimony was taken, and a motion was made at the conclusion of the evidence on behalf of the plaintiff, for a directed verdict in favor of the defendants. The principal grounds urged for the motion were that if any foreign substance was left in the patient's body following the operation, there was no proof that it was so left as the result of any negligence on the part of either defendant; further that there was no competent proof that any damages or disability suffered by the plaintiff were in any way attributable to anything done or omitted to be done by the defendants. The motion was granted and judgment directed in favor of the defendants.

An appeal was taken from the judgment, and the highest court of the State affirmed the ruling of the lower court. In deciding the appeal, the appellate court carefully went over the testiniony that appeared in the record, and unde clear the reasons why the pluntiff had failed to prove a case sufficient to justify a jury to award damages to the plaintiff. As the court said.

"In the case at bur, the claim is that infection resulted from the alleged failure of the defendants to remove a towel or surgical gauze from the wound made in plaintiff's abdomen in the course of performance by them of the operation for which they were employed. This infection, it is charged, caused the damage for which plaintiff seeks recovery. Necessarily, under the authorities, the burden rested upon plaintiff to prove that a towel or surgical gauze was negligently left in the wound by the operating surgeons. The testimony of Mrs. M is rehed upon to establish this fact.

"Dr H, who performed the operation, denied that any towel was left in the incision, but says that necessary gainze drainage was left in it, as he and Dr E feared pus, and that this was good practice in this case. He had previously testified that to leave any foreign substance in the wound was bad practice in a large percentage of cases."

"As the evidence in the case stood, if Dr H's statements relative to the gauze be regarded as true, then there was no proof of negligence in leaving the foreign substance in the wound Mrs M's oral testimony would seem to be in conflict with the statement in her memorandum jury would have been obliged to guess whether a towel or sponge was removed from the wound Only by disregarding the written memorandum and by giving such oral testimony its full value in conjunction with Dr H's qualified statement as to what constituted bad practice in most instances, could it be regarded as sufficient on the point for submission to the jury In this state of the reeord, and in view of the rule that, 'where the evidence is as consistent with the absence as with the existence of negligence, the ease should not be left to the jury, we are inclined to view it as at least doubtful whether, all things considered, the

burden of proof was sustained in this respect"

The court went on to point out that whether or not it could be assured that the plaintiff had made out a prima facie case of negligence, the proof was entirely lacking in testimony to show that any injury was or could with reasonable certainty have been caused by the alleged negligence. The opinion of the court said in part

"There remains the question of whether the plaintiff upheld the burden of proving the proximate causal connection between the alleged negligence and the damage suffered. The testimony of both Dr. L. and Dr. H. stands undisputed in the record that a sterile towel lelt in the wound would not cause infection—the admitted factor admittedly the source of the plaintiff's delayed recovery and most of the other ill effects following the operation

"It is contended by plaintiff in error that there was no proof that this towel-assuming that the article removed was a towel-was sterile this contention we are not inclined to agree der the rule governing the direction of verdicts hereinbefore given, deducing such inferences from Mrs M's testimony as may reasonably be drawn, we think it was fairly established that the towel in question was sterile. Without contradiction, she stated that hand towels were not used. and the towel removed from the wound was one such as is put up in the hospital in packs for operations, that these towels were employed as a sereen, bound and put lengthwise and crosswise (evidently about the operative area), and that it was a fact that all dressings used in the operation were sterile. It would hardly seem reasonable to conclude in view of her testimony as to the eareful sterilization of all dressings used in connection with the operation, that the towels employed in it were not sterilized, but that only the sponges furnished by her were so

"The proof in this case at bir was that sterilized cloths in the wound would not cause infection. In view of that proof and the other elements in the case, it therefore devolved upon plaintiff in order to carry the matter to the jury, to produce evidence that the towel was unsterile. This was not done. Indeed as we think, the evidence reasonably interpreted was to the contrary."

AMBULANT TREATMENT OF HERNIA

A doctor who had for several years made a practical study of ambulant treatment of hernia by injection was consulted by a middleaged man with respect to the possibility of treating a hernia from which he was suffering. The doctor's treatment consisted of an

injection of a very small amount of a certain preparation into the inguinal canal through the scrotum. The treatment necessitated the application by the doctor of a tight fitting truss which it was necessary for the patient to wear in order that the injection treatment could take effect. The single injection was administered to the patient and the truss fitted to him. He was supposed to return for further injections.

A few days later the patient communicated with the doctor, complaining that he had returned home and the discomfort from the truss had been so great that he could not wear it, and further claiming that the doctor had spilled some of the fluid on his scrotum causing him a great amount of pain. He demanded that the doctor pay him a sum of money for the alleged suffering, and since the doctor would not comply with his request he instituted a law suit, claiming negligence in the doctor's treatment.

The case came on for trial before a judge and jury and upon the trial the plaintiff produced photographs of his private parts which purported to show that an inflammation had developed subsequent to the injection by the doctor. On cross-examination the plaintiff revealed that upon returning to his home he had applied some disinfectant to his scrotum at the point of the injection which was apparently the cause of any discomfort that he might have suffered, rather than the truss or the injection made by the doctor. The trial judge sent the case to the jury who returned a verdict in favor of the doctor, thereby completely exonerating him of the charges brought against him by the patient.

N. Y. State J. M.

October 1, 1933

FRACTURE OF PELVIS CLAIMED TO HAVE RESULTED FROM DELIVERY

A woman about 31 years of age consulted the defendant doctor complaining of soreness in her lower left abdomen. His examination of the patient disclosed that she was four months pregnant with a sensitiveness and tenderness on the left side to the left of the uterus. She was complaining of pain which the doctor attributed to low grade chronic inflammation of the left tube and ovary. She had had an induced abortion several years previous and at that time it has been necessary for her to be operated upon for the removal of placental tissue. The doctor rendered to the patient prenatal care and in due course she entered the hospital to be delivered of her child. The delivery was made under general anaesthesia with the aid if a low forceps and was relatively simple, the forceps being used for only three minutes and no particular force being necessary to deliver the child. The child was abnormal and died several days after birth from congenital encephalitis. The patient remained at the hospital for about three weeks subsequent to the delivery and was seen practically every day by the doctor. She complained of increased amount of pain in her left side which was accompanied with a rise in temperature. The doctor, after examining her, diagnosed this condition to be an exacerbation of the old inflammation in the left tube and ovary. His record diagnosis of this condition was salpingitis. A few days later the pain gradually diminished in severity, her temperature came down to normal and she felt better, except

that she complained that when she moved her legs she had pain in her abdomen. Finally she left the hospital against the doctor's orders and he never heard anything further about the matter until suit was instituted against him, charging him with malpractice.

The plaintiff's claim was that in delivering the woman of a child the doctor had improperly applied his instruments so that he fractured her pelvis and displaced the coccyx. The case came on for trial and testimony introduced on behalf of the plaintiff disclosed the plaintiff's contention to be that in the delivery the doctor had caused three cracks in the body of the left pubic bone. X-rays were submitted in support of this contention which were examined by competent x-ray men on behalf of the defendant. The said witnesses for the defendant testified that they were unable to detect any indications of a fracture of the pelvis. The testimony as to the coccyx showed that only one segment was involved and that the claim was that it was displaced laterally only slightly.

The case was tried without a jury and after all the testimony had been put in the court directed a verdict in favor of the defendant.

An appeal was taken from the judgment cntered in favor of the defendant to the Appellate Division on the grounds that the Judge's verdict was contrary to the weight of the evidence. The Appellate Division. however, refused to disturb the ruling of the trial judge and the matter was finally terminated in the doctor's favor.

NEWS NOTES

THE CONFERENCE OF STATE SECRETARIES AND EDITORS

The annual conference of the secretaries and editors of the State Medical Societies, conducted under the auspices of the American Medical Association, was held on Friday and Saturday, September 22-23, 1933, in the Palmer House, Chicago, Ill.

About one hundred delegates were present from the several state societies; those representing the Medical Society of the State of New York were;

Dr. Peter Irving, Assistant Secretary

Dr. Orrin Sage Wightman, Editor-in-Chief

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education; and

Dr. Arthur W. Booth, Trustee of the American Medical Association.

The meeting was called to order by Dr. J. H. J. Upham, of Columbus, Ohio, Chairman of the Board of Trustees of the American Medical Association. Dr. Walter F. Donaldson, of Pittsburgh, Pa., Secretary of the Medical Society of the State of Pennsylvania, was chosen Chairman.

Meetings were held on Friday morning and afternoon, and Saturday morning, with a luncheon on Friday noon, and a dinner in the evening.

The program of the conference was of a practical nature and on a series of subjects of general interest to the medical profession of all the states.

The dinner on Friday evening was a "gettogether" evening held in the Trustees Lounge of the Hall of Science in the Century of Progress building at the Chicago Fair, under the auspices

of the Cook County Medical Society.

After the luncheon Dr. Dean Lewis, President of the American Medical Association, spoke on the subject, "The Quality of Medeal Care," pointing out some modern improvements in the education of medical students, so as to make them better practitioners of medicine. He mentioned the rise and fall of theories and principles of practice which are inseparable from medical progress, mentioning as an example the theory of focal infection and the necessity that doctors who have graduated ten years ago should keep themselves up-to-date in the subject.

Dr. Lewis also made a plea that doctors should learn and practice the most modern of bedside examination, so as to supplement the information given by the laboratory technician who does not see the patient. The most satisfactory doctor is he who can give efficient treatment on the basis of bedside examination.

Dr. F. C Warnshuis, Secretary of the Michi-

gan State Medical Society, discussed a survey of medical services of the State of Michigan, which have recently been made by the State Society and which is described in the New York Stat Journal of Medicine of September 1, 1931 page 1061.

Dr. Warnshuis discussed some of the developing trends in the practice of medicine and in that attitude of the people toward their physicians and the growing expectation that medical service wibe provided at public expense, including the in surance of hospital care on a voluntary basis.

The address of Dr. Warnshuis was intensivel discussed by several members including Dre Wightman of New York, Morrison of New Jer sey, McCormack of Kentucky, Biering of Iowa Taylor of Texas, and Sullivan of New Hamp shire.

Dr. Olin West, Secretary of the American Medical Association, summed up the genera opinion of the medical profession when he said that the fundamental principle of the practice o medicine was a contact of an individual doctor with an individual patient; and that insurance of health and of hospital care, or any other form of impersonal medical service would be unsatisfac-

tory to both doctor and patient.

Dr. E. A. Meyerding, Secretary of the Minnesota State Medical Association, described the exhibits, both scientific and commercial, at the annual meeting of his State Association, May 22-24, 1933. The exhibit booths were arranged so that there was room for a demonstration of their specimens and wares; and space was allowed for a considerable number of physicians to see and hear readily. The scientific sessions were dismissed for an announced hour, so as to enable the physicians to attend the exhibitors of both the scientific and commercial departments.

Dr. W. J. Biering, of Des Moines, Iowa, President-elect of the American Medical Association, discussed the "Education of Physicians in the Undergraduate Medical School," describing the great over-supply of doctors in the United States as compared with those in other countries, as is

shown in the following table:

United States . 1 to 700 inhabitants England . . . 1 to 1420 " France . . . 1 to 1690 " Sweden . . . 1 to 2890 "

Dr. Biering suggested 1 to 1200 being a fair distribution of doctors. Sweden has legislated to keep the number of doctors down to 1 to 2800,

and to control the admission and education of the students, but such a procedure would not be possible in the United States. However, he suggested dropping the lower one-third of each first year

Dr. J. E. Tuckerman of Cleveland, Chairman of the Committee on Medical Defense of the Ohio State Medical Association described the plan of defense against civil malpractice suits. One peculiar condition of assuming the defense of a physician is that he shall not have sued to collect his bill within one year of the termination of his services.

Dr. Thomas P. Farmer of Syracuse, Chairman of the Committee on Public Health and Medical Education of the Medical Society of the State of New York, described the postgraduate system of medical instruction conducted by the Medical So-

ciety, and enumerated some of the results as follows:

N. Y. State J. M. October 1, 1933

Sustained interest in county society activities Direct help to individual doctors

Increased use of laboratory methods and their interpretation

An increase in the amount and breadth of medical reading and study.

General improvement in the state of medical practice.

The Conference had a great value in promoting the acquaintance of the secretaries and editors, on whom the societies depend the most largely. Medical problems are universal in their nature and scope, and the exchange of ideas by officers from all sections of the United States promotes a unity of action and standardization of method throughout the nation.

SEVENTH DISTRICT BRANCH

The Twenty-Seventh Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York, was held on Thursday, September 21, 1933, in the College Auditorium on the River Campus of the University of Rochester. The registered attendance was 251, and the doctors were unusually cordial in their attitude toward one another, and responsive to the speakers on the program.

The Seventh District Branch is composed of eight county societies, whose membership was as follows:

Cayuga, 63
Livingston 32
Monroe450
Ontario
Seneca 22
Steuben 72
Wayne46
Yates
Total

The morning session was opened at 10:30 o'clock by the President, Dr. James M. Flynn, who introduced Hon. Charles Owen, Comptroller of the City of Rochester. Mr. Owen welcomed the physicians and referred to the aid which they render in prolonging the years of usefulness of those long experienced in the practical affairs of business and civic life.

The following officers were elected at the

business session:

President, Alfred K. Bates, Auburn; First Vice-President, Thomas W. Maloney, Geneva; Second Vice-President, Afred W. Armstrong, Canandaigua; Secretary, H. S. Brasted, Hor-

nell; Treasurer, E. T. Wentworth, Rochester. A noon luncheon was served in the students' dining hall of the University.

The State Institute for Malignant Disease sponsored an exhibit of photographs and x-ray

films illustrating its cancer research.

Dr. F. H. Flaherty, President of the Medical Society of the State of New York, gave a brief address urging the officers of the County Medical Societies to confer with their county welfare officials in order to reach agreements in regard to supplying medical service to the poor and those who cannot otherwise obtain it. Securing these agreements is of extreme importance to every County Society.

Five scientific addresses were listed, all of deep interest and great practical value.

Dr. Royal R. Sayers, Chief of the Industrial Hygiene and Sanitation of the United States Public Health Service, discussed the subject of silicosis; and the deleterious effects of silica dusts compared with the effects of other dusts. The specific effects of silica are the results of its solubility. Carbon, for example, is insoluble, and is therefore not toxic, although it may blacken the lungs with its deposits. But silica is slightly soluble, and has toxic properties in addition to the irritation of its mechanical presence in the tissues. Silica produces a characteristic fibrosis, and predisposes to tuberculosis.

Dr. Charles Gordon Heyd gave a talk, illustrated with lantern slides, on the subject: "The Mechanism and Clinical Interpretation of Jaundice." Dr. Heyd reviewed the source of the bile salts in the blood and the several mechanisms by which they are retained or

deposited in the tissues. The practical application of his address was a plea that doctors should bear in mind the physiology of jaundice and the various conditions that bring it about, such as vomiting leading to alkalosis, and diarrhoea leading to acidosis,-contrasting conditions which respond to appropriate treat-

Dr. Byrl R. Kirklin, of the Mayo Clinic, Rochester, Minnesota, gave an address on "The Diagnosis of Pulmonary Tuberculosis," with special reference to the peculiar field of

the x-ray. Dr. Arthur J. Bedell, of Albany, gave a talk on "Medical Ophthalmoscopy, the Connecting Link Between the Physician and the Specialist." Dr. Bedell showed photographs of the fundus of the eye in various diseases, using three stereopticons loaned by the Bausch and Lomb Company, and throwing three pictures on the screen simultaneously, in order to show contrasting conditions. He showed how the eye fundus may reveal conditions in their early stages while they are remediable. His talk was an argument for the use of the onlithalmoscope in two conditions:

1. In visual defects which are of rapid onset, often revealing kidney disease, lead poisoning, syphilis, or other serious condition.

2. In these same systemic conditions often revealing an eye disease in an early stage.

Dr. Fred H. Albee, of New York, spoke on "The Bacteriophage in Wound Treatment," tracing the history of the greater developments in the treatment of chronic infections of wounds through three stages:

The Carrell-Dakin method of irrigation

used in the World War.

2. The Orr method, or packing the wound with gauze impregnated with vaseline and leaving the material intact for days or weeks. 3. The application of bacteriophages to the

wound.

The first method depended on the constant application of an antiseptic to the wound and bacteria. The probable explanation of the second method was that the long presence of the packing in the wound permitted bacteriophages to grow in the wound.

Bacteriophages were first discovered in 1915, and about fifty varieties are known, each specifie for a single kind of germ. Doctor Albee's method of using them is to fill a wound eavity with a soft mixture of paraffin and vaseline, and to introduce the bacteriophages into the

wound daily through a eatheter.

A time schedule was followed, and every speaker began and ended on time.

PROGRAM OF THE FIRST DISTRICT BRANCH

The annual meeting of the First District Branch of the Medical Society of the State of New York will be held in the Grasslands Hospital (The County Hospital of West-chester County), in Valhalla, Westchester County, on October 11, 1933. The program is as follows:---

"The More Common 10:15---10:50 A.M. Cardiac Arrythmias; their Significance and Treatment," James F. Rooney, M.D., Albany.

Discussion—(ten minutes) Opened by Mil-

ton J. Raisbeck, M.D., New York,

11:00-11:35 A.M. "The Use of Quinidine Sulphate in Cardiac Arrythmias," Frederic C. Conway, M.D., Albany,

Discussion-(ten minutes) Opened by Fred

Holcomb, M.D., Kingston.

11:45-1:00 P.M. "Operative Clinics and Case Demonstrations in Chest Surgery," George C. Adie, M.D. Director of Surgery, Grasslands Hospital, and Assistants.

Luncheon Session 1:00-2:00 P.M. "State Society Problems," Frederick H. Flaherty, M. D., President, Medical Society of the State of New York. Daniel S. Dougherty, M.D. Secretary, Medical Society of the State of New York. Orrin S. Wightman, M.D., Editor, New York State Journal of Medicine.

2:00-2:35 P.M. "Motion Pictures Illustraing Normal and Abnormal Cardiac Mechanism and Electrocardiograph," Lewis M. Hurxthal, M.D., Lahey Clinic, Boston.

2:35—3:10 P.M. "Pulmonary Tuberculosis: Recent Types of Operation" (Illustrated), Howard Lilienthal, M.D., New York.

3:10-4:00 P.M. "The Management of Tuberculosis Cases Under Collapse Therapy" (Illustrated), J. Burns Amberson, M.D., New York.

Discussion-George C. Adie, M.D., John M. Nicklas, M.D., William G. Childress, M.D., of Grasslands Hospital Staff.

FOURTH DISTRICT BRANCH

The Twenty-seventh Annual Meeting of the Fourth District Branch of the Medical Society of the State of New York was held at Malone, N. Y., on Tuesday and Wednesday, September 19 and 20, 1933, at the Elks Club in that city.

The meeting began with a luncheon at the Hotel Flanagan attended by the officers of the Branch together with the Presidents and Secretaries and Chairmen of the Committee on Economics of the component County Societies. This conference was called by Dr. Raymond G. Perkins, President of the Fourth District Branch with the purpose of establishing a uniform fee table for treating welfare cases throughout the District. Views on the subject were expressed by various members from the different counties present, as well as by Dr. Frederick H. Flaherty, President of The Medical Society of the State of New York, and Dr. Joseph Lawrence, Executive Officer of The State Society. This Conference adjourned to be called again after the dinner at night.

The Scientific Session began at two p. m. at the Elks Club with remarks of welcome by Dr. R. G. Perkins, President, of Malone, N. Y.

The following papers were presented:

1. "Fractures and Dislocations of the Elbow," by Phillip D. Wilson, M.D., of Boston, Mass. This paper was illustrated by lantern slides and was a very exhaustive treatment of this subject and very profitable to all present.

- 2. "The Diagnosis and Management of Goitre," by Frank H. Lahey, of Boston, Mass. This paper was illustrated by slides and the subject of goitre was covered by Dr. Lahey in his usual searching and compressive manner.
- 3. "What the State of New York Plans to Do at Saratoga Springs," by Carl R. Comstock, M.D., of Saratoga Springs, N. Y. This paper was also illustrated and showed very interestingly what the State of New York had done and intended to do in developing this famous spring resort for the benefit of physicians and patients.

A rising vote of thanks was given to Drs. Wilson and Lahey for coming from Boston to present their two very interesting papers.

Before adjourning for the afternoon, Dr. Perkins extended the privileges of the Golf Club to those members or their wives present who might wish to play the course.

The Annual Dinner was held at the Hotel Flanagan at seven p. m. After a sumptuous repast, the following talks were given, the general subject being that of Medical Economics.

1. Address of Welcome. John W. Kissane, M.D., President of Franklin County Medical Society of Malone, N. Y.

2. "Some Thoughts on the Present Day Evolution of Medicine," by John Wyckoff, M.D.,

Dean, Bellevue Medical College, New York City.

3. "Why the County Should Compensate Physicians for the Care of County Cases," by Robert S. MacDonald, M.D., Plattsburgh, N. Y., Chairman of Economics Committee of Clinton County Medical Society.

4. "How Saratoga County Medical Welfare Is Handled," by Edward J. Callahan, M.D., Saratoga Springs, N. Y., President of Saratoga County Medical Society. This subject was discussed by the President of The Medical Society of the State of New York, Frederick H. Flaherty, M.D., Syracuse, N. Y.

An opportunity was then given for supervisors and welfare workers who were present to ask questions, but none took advantage of the invitation.

An adjourned meeting of the noon conference was then held at which time it was moved and carried that the President of the Fourth District Branch appoint a committee representative of the county societies of the District which committee would meet at a later date and consider the question of a fee table.

A morning session was held on Wednesday, September 20, 1933 at nine a. n., in the Elks Club.

At this session the following papers were presented.

- 1. "The Commoner Diseases of Colon and Rectum," by G. Gavin Miller, M.D., of Montreal, Canada.
- 2. "The Management of Persistent Occiput Posterior Position on Labor. With motion picture showing the thecnic used," by William M. Mallia, M.D., Schenectady, N. Y.
- 3. "The Diagnosis of Brain Tumors," by Wilder G. Penfield, M.D., Montreal.

A vote of thanks were given the speakers, and also to the Elks Club for the use of the rooms.

The Twenty-seventh Annual Meeting adjourned at noon.

The Fourth District Branch is located in the northeast corner of the State, and comprises ten County Societies whose membership is as follows:

Clinton	. 29
Essex	. 19
Franklin	. 51
Fulton	
Montgomery	. 52
St. Lawrence	61
Saratoga	
Schenectady	33
Warren	
Washington	
-	
Total	512

Sylvester C. Clemans, M.D., Secretary.

PROGRAM EIGHTH DISTRICT BRANCH

The Twenty eighth Annual Meeting of the Eighth District Branch of the Medical Society of the State of New York will be held on Flursday, October 5 1933, in the Cataract House, Niagara Palls N Y, beginning at ten o'clock by the morning.

in the morning The program is as follows
10 A M— Timely Economic Issues," by
Charles II Goodrich, M.D., Brooklyn, N. Y.
Discussion opened by Edward E. Haley, M.D.,

Buffalo

11 A M — "A Study of Diabetic Deaths from Autopsies" by Ivan Hekimian M.D. Buffalo, and Samuel A. Vogel M.D., Buffalo. Discussion opened by Byron D. Bowen, M.D., Buffalo. 12 M -Laurcheon and Introduction of Guests

1 30 PM—Business Meeting Election of Officers

2 P.M.—"What Every Doctor and Dentist Should Know About Cancer," by Joseph C Bloodgood, M.D., Baltimore Md

3 P M—'Advances in Cancer Research The relation to enzymes in cancer, and research in the mechanism of radiation effects," by Ellice Me-Donald M D, Philadelphia Pa Discussion by Burton T Simpson M D Bernard F Schreiner, M D, Louis C Kress, M D, and Herbert A Smith M D Buffalo

DUTCHESS-PUTNAM

The regular meeting of the Dutchess-Putnam Medical Society was held September 13, 1933, at Wassaie State School, Wassaie, N Y

The meeting was called to order by the Vice-President, Dr A W Thomson at 400 PM after inspection of the school and hospital. The following candidates were elected to membership

Dr Lotts D Goldberg—Pouglikeepste N Y Dr Reginald Berry—Stanfordville N Y

The following committee was appointed to prepare suitable resolutions for the late Dr W T Rivenburgh -Drs Sobel, J Newton Boyce and R H Breed

Scientific Program

Dr Steblen presented a case of juvenile paresis Dr Pense presented three cases of infantile cerebral palsy occurring in one family

Meeting adjourned at 5 00 P M for refreshments

Present 35

II P CARPENTER, Secretary

THE DAILY PRESS

THE DUTCH ELM DISEASE

There is a striking similarity between the contagious diseases of plants, and those of animils and man. A new disease now threatens the clins, whieli are among the largest and most beautiful trees that his our roadsides. The disease was discovered in the Netherlands in 1919, in England in 1927, and in Cleveland, Ohio, in 1930. The New Yorl Sun of August 25 says editorially.

'The first symptom of the disease is sudden wilting of the leaves of part of the crown of the tree, of the entire tree, or the tips of some branches Defolation may follow, the wilted leaves turning yellow or brown before

falling

'Progress of the disease varies with trees. In some cases it may kill in a season. In others the tree may survive for several years, the fungus spreading slowly. According to European investigators they have found that trees become infected through buds, twigs, limbs, trunks or roots. The fungus grows principally on the sapwood. In Europe spread of the disease is now believed to be accomplished by the clin bark beetle, Scolytus scolytus Fabr, which earnes the fungus on its body, wounds the tree and introduces the disease through the wound. This beetle has not been found here, but other insects may perform a similar disservice.

'The fungus causing the disease is closely related to organisms that produce blue stains in pine, gum and other trees. At present it is sometimes impossible to tell from examination in the field whether a wilted elm is a vietim of the Dutch elm disease because other fungi and becteria produce similar types of diseolor ation. Laboratory examination is necessary

to reach a decision

'No cure is known for the Dutch clm disease unless it is localized in a limb that can be removed. The United States Depurtment of Agriculture says that as the disease is still

in an incipient stage here the only logical program in fighting it is to find and eradicate stricken trees, delay may result in loss of the opportunity to eradicate it, and the elm may follow the chestnut

When it is feared that the disease has fastened on a tree a specimen twig or small braneli about ten inches long from the affected portion should be sent to the Dutch Elin Disease Laboratory Agricultural Experiment Station, Wooster, Olio, with a letter gring all available information concerning it

"It is possible that the disease is not yet so firmly established here as to resist a general cooperative attack on it. The elm is one of the noblest of trees and no effort that will eliminate or stay the Dutch elm disease is too costly or too arduous to be undertaken."

They do things differently in England where presention is practiced. The New York Herald Fribine of September 7 carried the following item as front page news under the caption 'British Calin Shattered by Three Little Potato Bugs'

"After an intensive search the Ministry of Agriculture has discovered that Great Britain

his only three potato bugs

'Specimens found wandering about Tilbury Docks started a tremendous hue and ery. The country side was decorated with warning notices. Harassed experts in Whitehall dashed from patch to patch, while restrictions on French imports were tightened. One newspaper lightly reported that milhons of bugs had been killed in the County of Norfolk.

'Now the country breathes again. The ministry officially announced today that it has been able to discover only the Tilbury trio

No beetles have been found in any other part of the country,' the announcement adds, despite careful search of potato crops in areas in which the Colorado beetle might be most likely to make its appearance.'"

QUESTIONNAIRES

The semi humorous column on the editor al page of the New York Times of August 20 entitled "Topics of the Times is on the subject of questionnaires, written in mutation of Alice in Wonderland Alice, addressing the Mad Hatter said—

Dr Mayo says that once upon a time clul dren were never told the truth Nowadays cluldren are told everything. He likes the new way better. But I wonder if this means Dr. Mayo is opposed to fairy tales for children? I should be very sorry if he was."

"So should I," said the Hatter. "I came across a perfectly lovely fairy tale the other day. Would you like to hear it? It's about an Ant and a Grasshopper."

"The Ant works all Summer and the Grasshopper sings. But when the frost comes, it is the Ant who is cold and hungry and he applies to the Grasshopper for relief. 'What were you doing all Summer?' said the Grasshopper. 'Working my head off,' said the Ant. 'Well, you darn fool,' said the Grasshopper, 'what did you expect? You went and piled up a Surplus, and smashed prices to smithercens, and now you are out of a job on account of overproduction, and your purchasing power is nil. You should have done the way I did and gone in for a good time all Summer. We would have created between us an economic vacuum that it would take the factories five years to fill up."

Alice shook her head. "I don't think it sounds very interesting for a fairy story for children," she said; "It would be quite a nice story for grown-ups."

The March Hare looked up.

"Sure you are allowed to have fairy stories for grown-ups," he said. "But you must always begin by saying, 'It is stated here in circles close to the Foreign Office that when Goldilocks heard the Three Bears coming into the house she did so and so."

But Alice wasn't listening.

"I should hate to think of children without fairy tales; and always being told the truth about everything the way Dr. Mayo says Think of telling a child everything!"

"It won't hurt them the least bit," said the Hatter. "Children can stand anything. The March Hare is right. It's the grown-ups that cannot get on without fairy tales. First they make up a fairy story and then they put the scientific and statistical foundations under it."

The March Hare looked up.

"Don't you love questionnaires?" he said. "You send a questionnaire to 8,000,000 children under the age of 11 asking whether they think Debentures are a sounder investment than Short-term Certificates. You get a reply from 843 children. You publish the results for grown-ups to read."

MEDICAL EXAMINATION OF SCHOOL CHILDREN

What progressive newspaper editors think of the medical examination of school children is shown by the following editorial in the New York Sun of August 25:

"The Health Commissioner has appealed to all parents who can afford it to have the necessary examinations made by their own physicians. The response to this appeal should be immediate. The attitude of physicians is typically displayed by those of Brooklyn; their county society, cooperating with the Tuberculosis and Health Association, has distributed forms approved by the Health Department to remind parents of the requirement of the law.

"It is distasteful to practitioners of medicine to do anything which might be interpreted as forcing their services on their pa-

Many physicians are so careful in this that they lean over backward. unfortunate; there are many situations in which patients are greatly benefited by af-firmative acts, by urgings on the part of physicians. In the matter of examinations of children for admission to school the physician who calls the provisions of the law to the attention of his patients is doing no more than a citizen's duty. It is not enough to say that everybody knows the law; some parents may be ignorant of it, and among those who know it there is the usual proportion of the neglectful, procrastinating and forgetful. The schools will soon open for the autumn term and the doctors, along with the others, should do their part to get the children ready for them."

BOOK REVIEWS

HUMAN VALUES IN PSYCHOLOGICAL MEDICINE. By C. P. BLACKER, M.D. Octavo of 179 pages. New York, Oxford University Press, 1933. Cloth, \$2.50. (Oxford Medical Publications.)

In the preface, the author acknowledges his debt to the genius of Freud in so powerfully influencing psychological medicine. The author is well versed in Freud's writings, but disclaims membership in the recognized psychoanalytic group of his country. He has displayed interest in philosophy and biology. In the book the author elaborates upon various phases of values in life as held by the general person and especially by the mental patient. He emphasizes the personal characteristics and idiosyncracies of individual sufferers from mental diseases, and particularly in the realm of the person's affective reactions.

The average physician would enjoy this philosophical approach to a most interesting subject.

IRVING J. SANDS.

THE NERVOUS CHILD AT SCHOOL. By HECTOR C. CAM-ERON, M.D. 12mo of 160 pages. New York, Oxford University Press, 1933. Cloth, \$1.50. (Oxford Medical Publications.)

The author considers the problem of the child in relation to school life. As a preliminary he stresses the need of home understanding, especially the function of parents in instilling self-confidence on the part of the pupil. The factor of fatigue is stressed as it produces disorders of health such as vomiting, abdominal pains, rise of temperature and disorders of sleep. The author emphasizes the relationship of fatigue and unhappiness in school life. He indicates that the development of such delinquencies as persistent lying, stealing, truancy, and masturbation may be related to these factors. Disorders of micturition and speech are also discussed. There is also a chapter on special ability and disability.

The book is well written and simple in its style.

offers a common sense view of difficulties in school life and their treatment. It is a valuable addition toward the understanding of the so-called nervous child.

STANLEY S. LAMM.

Neurological Effects of Syphilis. Diagnosis and Treatment. By Bryan B. Sharp, M.D. Octavo of 92 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$2.00. (Oxford Medical Publications.)

This book is divided into two parts. The first being concerned with diagnosis and the second with prevention, treatment and prognosis. The various types of syphilis and para-syphilitic diseases of the central nervous system are described including tables and G.P.I. The tem are described including tables and G.P.I. The changes in the blood and spinal fluid are discussed. Congenital neuro-syphilis is treated separately.

Under therapy, the malarial treatment of syphilis is reviewed. Treatment with other forms of pyrexia is shown, such as relapsing fever, vaccine, sulphur and

diathermia.

There is a satisfactory bibliography. This book is of value for a quick review of the subject of neuro-STANLEY S. LAMM. syphilis.

LIGHT THERAPY. By FRANK H. KRUSEN, M.D. Octavo of 186 pages, illustrated. New York, Paul B. Hoeber, Inc., 1933. Cloth, \$3.50.

Krusen in his book on "Light Therapy" has assembled quite an array of facts and fancies from authoritative

or as near authoritative sources as possible in this "chaotic" subject of light. He has collected this array of data and with his own background attempts to give an up to the minute survey of the general subject. This is a difficult task for any one man.

He readily admits borrowing here, there or wherever he can, information which will help his subject matter.

The book is thorough, very thorough.

His Table of Spectral Sources as based on studies of Coblentz is good. His analyses of this table as he proceeds with the work is in one instance not up to the usual, e.g., Cold Quartz Lamp. To dismiss the subject of Visible Rays with the dictum, "The possible psychic effects of various colors is not in the realm of this discussion," is not up to the completeness nor standard of the rest of the book. He is to be commended for his position on Pulmonary Tuberculosis. It undoubtedly will create considerable discussion.

The references cited are alone worth the price of the bok.

John J. Hauff. book.

OBSERVATIONS OF A GENERAL PRACTITIONER. By WILLIAM N. MACARTNEY, M.D. Octavo of 478 pages. Boston, Richard G. Badger, The Gorham Press, [c. 1932].

This is an unusual book written for the general practitioner, especially the country doctor. The author treats briefly of nearly all discases in a rough and ready fashion, his own observations forming the basis of the

work, he preferring this method with its incompleteness, to what he calls the "copy cat" type of writing.

The relative advantages of country and city practice are discussed, the writer preferring the former with its opportunities of enjoying nature, going fishing or roaming in the woods. There is much information furnished which is generally sound country the wide follows. which is generally sound, considering the wide field covwhich is generally sound, considering the wide held covered. Besides the chapters dealing with specific discases, there are others, among them, "The Young Doctor," "Beginning Practice," "Specialism," "The Therapeutic Nihilist," which is very good; "The Dead Beat," "Domestic Nursing," and "The Doctor in Court."

There are many observations recorded. In those parishers are many observations recorded.

tients in whom morphine causes vomiting, the drug is said to be well borne if hyoscine is given with it. Having an opportunity to try this the day after reading it, the reviewer found it to work and his respect for the book increased. If solutions of homatropine, esering, nitrate of silver or cocaine are dissolved in salicylic acid water, one-quarter grain to the ounce, they will remain colorless, it is stated, instead of becoming cloudy.

The author remarks that one critic who read the manuscript said that some of the humor was too coarse, and he pleads guilty, having written for the "plain and in-elegant country practitioner who feels that humor can be drawn so fine as to be impalpable." Most chapters end and often begin, with a joke or story, some good and some not.

W. E. McCollom.

OPERATIVE SURGERY. Covering the Operative Technic Involved in the Operations of General and Special Surgery. By Warren S. Bickham. M.D., and Calvin M. Smyth, Jr., M.D. Vol. VII. Octavo of 849 pages, illustrated. Philadelphia, W. B. Saunders Company, [c. 1933]. Cloth, \$10.00.

This supplementary volume appears after a period of eight years in order to bring the subject matter in the previous six volumes of this work abreast of the times with the many advances that have been made in the field of surgery.

In reviewing the new work one is again impressed with the first clipper. The two pages devoted to the status of the surgeon, operative surgery and of the patient are well worth reading by the layman and the surgeon fivery young surgeon should read it and attempt to follow. It bespeaks in idealism in the practice of surgery that could come only from a man of inderstanding heart.

No surgeon will agree with all the operative technique that the author has selected—such agreement never could be hoped for However, the general selection of technique has been excellent and in this way the new volume supplies a valuable text for the student and practicing

surgeon

There are thirty six chapters covering over six hundred pages on all the more common operations that occur in general surgery as well as the specialties. The books well illustrated well written and a most useful book to have at one's elbow

ROBERT F BARBER.

Psycho Analysis Tonai Its Senpe and Limition Edited by Sandor Lorand, M.D. Octavo of 370 pages New York, Covici Friede, 1933 Cloth, \$425

Man Ins mastered the elements of nature to satisf, his wants. He flies in the air, sails under the seas, exploits the resources of the earth and communicates with his fellow beings thousands of miles away. Yet he has failed to master human nature, because he does not understand the basic fictors underlying human behavior. Hence the apparent paradoxes of man's behavior towards his fellow beings. For instance, one does not hear of the fifteen millions of the youth of the world who had lost their lives in the late war, but one continuously listens to the rasping sounds of the dickering of war debts, etc. Psychoanalysis throws some light that en ables one to analyze this apparent rhapsody of incoherence in human conduct.

The editor of the book enlisted the aid of twenty three active workers in the field of psychoanalysis and has produced a book that contains in simple and lucid terminology, the salient points of psychoanalysis as it has developed and as it is understood today. To those who have a knowledge of psychoanalysis the book will prove quite refreshing. To those who do not it may serve as a stimulus to further pursue this fascinating subject. To those who are still influenced by their own meconscious blinding conflicts and feelings of guilt and regard psychoanalysis as a synonym for sex, the book may prove of considerable educational value as it will enable them to realize that the most progressive and cul tured of the educators teachers theologians and thinkers regard psychoanalysis as the most enlightening means of understanding human conduct. The hook is well written and technically well printed so that it occupies a high place in medical literature.

IRVING J SANDS

AMERICAN AND CANADIAN HOSPITALS CLARK FIFTELD with the cooperation of the American Hospital Association Quarto of 1560 pages Minne apolis Minn Midwest Publishers Company, [e 1933] Cloth, \$10.00

'American and Canadian Hospitals" is a bonanza of historical, statistical and other pertinent information respecting American and Canadian hospitals and allied institutions

Among the dart given for hospitals and illied institutions are the following brief historical sketch types of service rendered type of control endowment isso cation memberships and approvals value of buildings grounds and equipment, amount and sources of income operating expenses average bed patient daily cost daily rates for private, seemi private and ward patients operating room fee, number of patients cared for dur

ing the year, average daily number of patients, number of interns, number of attending staff, average number in school of nursing, number of graduate nurses regularly employed, etc.

There are interesting and valuable reports on such organizations as the American Hospital Association, with whose cooperation this volume was edited, the American College of Surgeons, the Callolic Hospital Association of the United States and Canada, the American Protestant Hospital Association, and several others

The Appendix is of especial interest, containing historical sketches of all religious orders, both Protestint and Catholic, engaged in hospital work, information respecting the United States Public Health Service, the Veterius Administration, the National Tuberculosis Association endowments and funds devoted to the advincement of health, and many other hospital and medical

organizations

This book should have a strong appeal for the hospital executive, because the fiscal data presented will enable him to compare his financial structure with those of institutions of similar classification and possibly suggest to him the need for a study of costs in relation to income. To the general public, most of whom must sooner or later avail themselves of hospital facilities, 'American and Canadian Hospitals' is a mine of valuable information in easy reference form.

TREDERIC DAMRAU

ASTIMA, HAY TEVER AND RELATED DISORDERS A Guide for Patients By Samuel M Frinderg, M D 12nio of 124 pages, illustrated Philadelphia, Lea & Febiger, 1933 Cloth, \$150

Dr Feinberg in his new, small book fulfills all expectations. It is a simple, non-technical explanation of

allergie plienomena for the average layman

After describing the varied emises of asthma, he explains the necessity for detailed investigation of the patient through the history, stressing environment and food. It is an excellent survey of the known facts, and should be helpful to anyone suffering from any form of lypersensitiveness Dorottea D Curnow

ACIDOSIS AND ALKALOSIS BY STANLEY GRAH M. M D
& NOAH MORRIS M D 12mo of 203 pages Balti
more, William Wood & Company, 1933 Cloth, \$2.75

This book of 203 pages will answer most of your questions regarding Acidosis and Alkalosis. The definitions of acidosis, alkalosis ketosis, and alkaline reserve are simplified so as to be readily grasped. Van Slyke's unit prossible variations of acid base brlaince are given but the authors prefer Hildane's classification of four variations into a Acidosis (non gaseous), 2 Acidosis (gaseous), 3 Alkalosis (non gaseous), and 4 Alkalosis (gaseous) The defences against acidosis, comprising also buffer action in blood and tissues are taken up in detail. According to the authors. The multiplicity of the tests devised from time to time for the recognition of acidosis and alkalosis is ample proof of the difficulty of finding any simple, and at the same time accurate method of determining the state of the acid base equilibrium. Apart from the actual determination of the pH there is not, nor is there likely to be a single test which can be considered mfallible. Hence we would stress the necessity of taking into account the clinical history and findings as well as the laboratory tests in coming to a decision." And they further say that unless you know the pH that is normal for each individual an isolated reading of that figure may be of little value.

Diabetes nephritis gastro enteritis, cyclical vomiting, tetany and pyloric stenosis are discussed from the stand point of acidosis and alkalosis

Many helpful diagrams add to the clarity of the text
ARCHIBALD D SMITH

OUR NEIGHBORS

CLINIC ABUSE IN MISSOURI

The September issue of the Journal of the Missouri State Medical Association has an editorial on a plan for correcting the abuse of free clinics which was proposed by the St. Louis County Medical Society, and approved at a conference of representatives of the physicians, the leading welfare organizations, the Missouri State Medical Association and the St. Louis County Hospital when the problem was the most extensive. The Journal says:—

"The plan is termed the 'certification of the indigent.' No free cases will be accepted by the hospital, except acute and emergency cases, without being referred by a physician. Each physician in the county is furnished with blanks for the patient to fill in and sign. Aside from identification of the patient the blanks require him to give full particulars as to his financial condition, the questions being so formed as to make clear the conditions which make it impossible for the patient to pay although not destitute. The patient makes affidavit to these statements and thus becomes liable to six months' imprisonment or five hundred dollars fine if he makes a false affidavit. Mr. Arthur Anderson prosecuting attorney of St. Louis County, said he would heartily cooperate in the enforcement of this legal phase.

"At a dinner given to Dr. W. G. Patton, superintendent of the hospital, July 15, Dr. Patton outlined some of the difficulties encountered and the manner of handling them. Dr. Patton said: 'There is an impression among some people of St. Louis County that if they pay taxes they are entitled to free treatment at the hospital. This impression is wrong as the hospital was built by the taxpayers of St. Louis County to provide medical and surgical care for the indigent poor. We have thirty private beds for the taxpayers and the general public who are able to pay for the private physician and the hospital fee.'

"At the present time if a man owns a home it is difficult and often practically impossible to borrow enough money to take care of his immediate medical and surgical needs. Consequently, when people who own a home are seen at a free clinic for treatment or hospitalization it creates the false impression that those persons are abusing the free clinic. You can readily see that a wrong conclusion is drawn by the physician as well as the laity for, as a matter of fact, these people are themselves much embarrassed because they find it necessary to appeal for charity service. They must be taken care of and it is impossible for the management of free hospitals to refuse them medical care.

"We have a splended investigator who investigates all cases that apply for hospitalization and I feel that we have been reasonably successful in preventing any unusual abuse at this hospital.

"On July 10 we inaugurated a policy at the hospital requiring patients who apply for treatment at the clinic or for hospitalization to secure a letter from an active practicing physician stating that they are deserving charity patients and are not able to pay a physician or a hospital for medical care."

COMMITTEE ON PROFESSIONAL CONDUCT IN CALIFORNIA

The August issue of California and Western Medicine contains an editorial commending the medical society of San Francisco County for instituting a "Committee on Professional Conduct" to act when a member is sued for malpractice. Commenting on the action the Journal says:

"The San Francisco method puts teeth into the Principles of Professional Conduct and should have a deterrent influence on members of the medical profession, who, knowingly or otherwise, give support to certain types of attorneys of a class that may be said to be typified by the group known as 'ambulance chasers.'

"It is of importance to know that the activities of the committee are regarded as confidential procedures in all cases (except when appeal is requested by some party to its arbitrations), thor-

oughly to guard members and others from any annoyance or humiliation which might arise from publicity or gossip in some of its cases.

"San Francisco physicians are in a precarious situation in the matter of malpractice insurance protection. Our city is cited as the high spot in the country for lawsuit losses by the carriers of this form of insurance. To assure ourselves of further protection it is imperative that there be a rapid decrease in malpractice claims and suits. Two definite elements are at play causing them. One is looseness of tongue of physicians regarding the work of other physicians which gives origin in the patient's mind to suspicion, resentment or the suggestion that here is an easy racket to 'shake him down' for a considerable sum of

(Continued on page 1180-adv. xii)

If this tired, worried, over-worked mother were using Pablum for her behind and the definition of the period of losing her temper while her children clamor for the in the certal bowl, simply by adding water or milk of any temperature.

GETTING up an hour earlier in the morning is an inconvenience for most persons, but for the mother of young babies it is a hardship, sometimes almost tragic, frequently nullifying the best-planned pediatric advice.

This is especially true in the case of the nursing mother whose supply and quality of breast milk are affected by emotional shocks resulting often in agalactia and sometimes giving rise in the baby to diarrhea, colie, and even convulsions. Furthermore, the mother's emotional stress brings about a train of behavior on her part which is reflected in the child's psychologic reactions so that a vicious circle of bad habit formation is set up.

From this angle, the recent introduction of the pre-cooked form of Mead's Cereal, known as Pablum, assumes new importance in the doctor's psychological handling of both mother and child, quite aside from its nutritional value.*

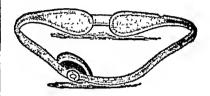

Because Pablum can be prepared in a minute, the mother can sleep the extra hour she would otherwise be compelled to spend in a hot kitchen cooking cereal. Added rest means better poise, so that petty annoyanees do not bring jaded nerves. Prompt feedings prevent many childhood tantrums, and a satisfied baby usually eats better and enjoys better digestion and growth.

*Like Mead's Cereal, Pablum represents a great advance among cereals in that it is richer in a wider variety of minerals (chiefly calcium, phosphorus, iron, and copper), contains vitamins A, B, E, and G, is base-forming and is non-irritating. Added to these special features, it is adequate in protein, fat, carbohydrates, and calories. Pablum consists of wheatmeal, oatmeal, cornmeal, wheat embryo, yeast, alialia leaf, and beef bone.

money. Ideas of this nature readily snowball into large proportions, especially when a lawyer of doubtful integrity foresees a sizable contingency fee in prospect. But let it be distinctly understood that no muzzling of medical men is intended. The by-laws and the committee do, however, distinctly point out that disparaging speech concerning the conduct, opinions, and treatment of another member of the profession shall not be indulged in with impunity until and unless he has made himself impartially familiar with the facts and circumstances obtaining at the time cited in such criticism.

"The second element conducing to our high 'mortality' is the ease with which some physicians can be paid to give unsound but convincing testimony against a colleague in a malpractice suit. To counteract this it is stipulated that physicians shall now notify the committee of intention to assist in a case before they do so, and shall give their reasons for so intending. Again it must be clearly understood that the by-laws and the committee are not to muzzle any person in such matters. They 'shall respect the privilege of every member to testify in any case as his conscience and opinion may dictate, and shall act in all matters with due regard to the rights of the patient."

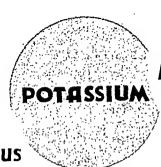

LIABILITY INSURANCE IN ALABAMA

Liability insurance has certain legal aspects of which many physicians are not aware. A fundamental consideration which is often overlooked by physicians is the authorization of the company to do business in the State in which the physician lives. The doctor naturally assumes that a company writing insurance has that authorization from the State Department of Insurance, but many companies doing an active business do not have that permission. The August Journal of the Medical Association of Alabama calls attention to this condition in the following editorial:

"Two years ago the Secretary of the Association issued a statement to the profession regarding policies against loss from liability imposed by law for damages on account of bodily injuries or death suffered by any person or persons in consequence of error, malpractice, or mistake. At that time the members of the Association were warned not to do business with any company that could not present proof that it had qualified with the office of the State Superintendent of Insurance.

"Despite such admonition it appears that certain ones have fallen prey to wildcat liability insurance with the result that they have no redress when protection is needed. This further warning, therefore, is given and concluded with the fol-

MANGANESE

PHOSPHORUS

An Aid In Fighting Chronic Sepsis

Chronic cholecystitis, chronic prostatitis, chronic colitis are but a few of the rather common conditions which give rise to a state of chronic sepsis.

Fellows' Syrup has proved to be of decided value in aiding the fight against the constant septic factors. Its ingredients: Manganese and Iron regenerate the impoverished blood stream; Calcium re-excites the dormant defensive mechanisms; Sodium, Potassium and Phosphorus overcome the troublesome psychoasthenic elements; Strychnine is of value as a stimulant to the respiratory asthenia; and Quinine is a distinct metabolic stimulant.

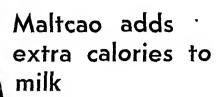

Fellows' Syrup in these conditions supplies the required mineral elements. The dose suggested is one teaspoonful in half a glass of water four times daily.

tary for advice regarding it."

NEWSPAPER PUBLICITY IN SOUTH CAROLINA

The July Journal of the South Carolina Medical Association contains the annual report of the State Committee on Public Health and Instruction which says:

"We instituted a plan of public instruction on fundamental and vital matters of health through the lay press by clear and concise articles, written by the doctors of S. C., but printed unsigned. Prior to the letters being sent to many and various doctors scattered all over the state, Dr. Young wrote to practically every S. C. newspaper, outlining the plan and asking for editorial co-operation. Quite a number of editors replied and promised their assistance.

"After the incoming medical papers from the doctors had been received they were carefully read and edited. In some instances they had to be considerably abbreviated, so as to conform to the space requirements. The articles were then sent to Dr. Hines who distributed them at proper intervals to the newspapers who had agreed to publish them, and who had kindly offered their columns free. Later on some of the editors became weary and supported us but feebly, while one opposed us as being propagandists, and selfish. The great majority however have been very kind and most helpful. To the press in general we are grateful for counting all sorts of newspapers from daily to weekly, etc., sixty-five of them have printed some or many of our articles. Without their assistance nothing could have been done.

"The subjects ranged from Appendicitis and Prevention of Heart Disease, to the Education of a Doctor, Prevention of Diphtheria, and Preparing for Motherhood. The committee feels that the campaign has not been all that we could have wished; that is we would have preferred more contributions, and more papers published. But even so a large number of people have read some of the material, and some have become interested and edified. No one can say whether we really have succeeded, but all in all the Committee believes that the State Association has made a beginning in educating our citizens as to what Modern Medicine stands for, and what Medical Science offers to those who come for help in time."

EMERGENCY RELIEF ADMINISTRATION IN NEW JERSEY

The August issue of the Journal of the Medicol Society of New Jersey carries the following announcement of the methods which have been adopted by the Medical Relief Committees of the Medical Society of New Jersey, at the invitation of the State Emergency Relief Administration. This announcement has been sent to every County Medical Society in the State:

"We have agreed to set up in each County a special committee, to be known as the Medical Relief Advisory Committee, to cooperate with the County Director in order that the principles set forth in this plan may be started into operation.

"The Committee, therefore, requests you to take the following immediate steps:

"1. The County Society shall appoint or elect a committee, of not less than five members, to be known as the County Medical Relief Advisory Committee.

"2. This Committee shall immediately prepare, for submission to the County Director, a list of licensed physicians within the county who are willing to accept Emergency Relief work.

"3. The Committee shall contact the County Director of Emergency Relief, at once, to arrange a fee schedule for Emergency Relief clients.

"4. While the maximum fees of \$1 for an office call, \$2 for a house visit, and \$25 for an obstetric patient, have been agreed upon; the rate for your individual County shall be based upon a proportion of from 1/2 to 3/3 of the prevailing average fees in your County.

"Several parts of the plan are worthy of spe-

cial attention:

"Doctors shall strive to take care of these clients in the home and shall refer them to the hospital for emergency conditions only.
"The method of submitting bills should be care-

fully studied and it should be noted that no patient shall be charged to the Emergency Relief Administration without proper authorization.

"The Committee stands ready to assist, in any way possible, to help in organizing or to smooth out troubles. We have promised the Emergency Relief Administration the whole-hearted coopera-

tion of the profession."

The authorization for medical calls, the presentations of bills, costs of hospitalization, and other administrative details fill a page of the Journal. The plan is an excellent example of cooperation of the State officers with the medical profession in providing medical service to the poor on a basis which is satisfactory to the patient, the doctor, and the State.

GRADUATE EDUCATION IN WASHINGTON STATE

The June number of Northwest Medicine has the following editorial announcement of a course of lectures to be given to the medical profession by the University of Washington.

"The University of Washington Extension Department will present its medical lectures, July 17-21, at Guggenheim Hall, Seattle. Since there is no medical department connected with this institution, these lectures represent the effort of the university to contact the medical profession of Washington and the Northwest each year in an endeavor to bring them the latest developments in the progress of different branches of medical science. During this designated week lectures will be delivered each day by Dr. L. A. Buie of the Mayo Clinic on Proctology; Dr. C. F. Fluhman of Stanford University Medical School on Ob-

stetrics and Gynecology; Dr. T. B. Futcher of Johns Hopkins University Medical School on Medicine and Therapeutics and Dr. A. C. Strachauer of University of Minnesota Medical School on Surgery. The details of the program of these lectures are presented in the announcement on page 7 of our advertising section. The lectures will be delivered at such morning and afternoon hours as to interfere least with the practice of those in attendance. Each evening a lecture will be delivered on non-medical topics by leading members of the University of Washington faculty. This occasion has always been profitable for social contact, bringing together for a period of the week medical friends from widely separated localities. The management trusts that a good attendance will be present.

HEALTH INSURANCE IN WEST VIRGINIA

The April issue of the West Virginia Medical Journal contains the following editorial on an experiment in health insurance in the State:—

"A new plan of sickness insurance has been inaugurated in the southern section of the state which appears to have considerable merit. The organization is known as Associated Hospitals, Inc., and its directorate is made up of one representative from each hospital in the area covered

A Maternity Support Typed for the Large Woman

In properly fitting an expectant mother with a maternity support, a tall, slender figure requires a straight-line model; a small, petite figure, a short, lightly boned one; a large, well-developed figure, a full, long-hipped one. Camp garments are proportioned to all figure types in stature and other individual respects.

An example of a proper model for the large woman with heavy thighs (No. 3123) is illustrated on an actual seven-month pregnancy case. Like all Camp maternity supports it possesses the exclusive Camp Patented Adjustment feature which adapts it to figure and to changes in pregnancy. In this case, it has one set of adjustment straps with extra lacing from waist to top. It provides firm under-abdominal and sacro-iliac support and relieves undue pressure on organs.

Approved and recommended by leading physicians. Sold by Sungical, Drug and Department Stores and Corset Shops. Write for Physician's Manual.

FOR ANO-RECTAL DISTRESS

RELIEVE PAIN...CONGESTION WITH

WYANOIDS

WYETH'S HEMORRHOIDAL SUPPOSITORIES]

The success factors of this new Wyeth suppository are based on

- 1. A well-balanced formula
- 2. A practical shape

THE FORMULA:

Combines the shrinking effect of Ephedrine, the antiphlogistic and astringent actions of Bismuth Oxylodide, with the antiseptic and healing qualities of Boric Acid and Zine Oxide.

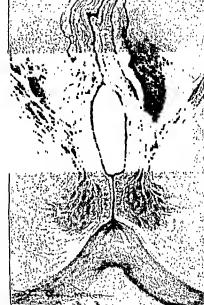

THE SHAPE:

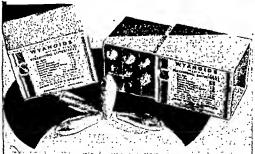

The improved "torpedo" shape of Wyanoids is anatomically correct. It conforms to the contour of the canal, is easily inserted, easily retained.

Wyanoids allay inflammation, relieve tissue engorgement and pain. They are soothing, healing, non-irritating, and since they do not contain opium, may be used at frequent intervals without harmful or constitutional effect.

Control the integrity of your prescriptions by specifying Wyeth's pharmaceuticals

Write for a box of Wyanoids for clinical test.

JOHN WYETH & BROTHER, INC.

PHILADELPHIA, PA. WALKERVILLE, ONT.

(Continued from page 1184—adv. xvi)
by the corporation. Associated Hospitals, Inc.,

furnishes only hospital service to its members.

"The chief merit of this new organization is

that all hospitals within the area participate in the plan and thereby avoid the disastrous results of solicitation. All subscribers to the fund have free choice of both physician and hospital: The hospital bills of all patients are paid from the fund according to the service rendered. Service is not rendered in the case of injuries covered either by Workmen's Compensation insurance or automobile liability insurance.

"At the present time the entire southern section of the state is covered by scattered contracts for sickness insurance with a lay corporation owned and controlled by private interests at Welch. Therefore, the progress of this new cor-

poration, which is exclusively in medical hands, will be watched with interest. If this new group, operated along ethical lines, can take control of the sickness insurance field in southern West Virginia, then a great step will have been made. We will then have at least one example of doctors and hospitals controlling their own destiny.

"This Journal does not advocate the organization of health insurance plans throughout the state, nor does it endorse any particular plan in any particular community. We do feel that in some sections where there is an unquestionable demand for some health insurance plan, the doctors and the hospitals would be wise to work out a satisfactory solution before someone else works out an unsatisfactory plan. We see no reason why any county society or any group of hospitals should hold aloof from such a move."

INSANE IN NEBRASKA

A practical suggestion for relieving the overcrowding of the mental hospitals of Nebraska is contained in the following editorial in the May issue of the Nebraska State Medical Journal:

"The suggestion made by Dr. J. C. Nielsen, Superintendent of the Norfolk State Hospital, that in these times of financial stress, admissions be placed on a 'barter' basis, seems at first thought somewhat shocking. The suggestion had its origin in the fact that the available capacity of the hospital is taxed to the utmost, and additional buildings will not be available for at least three years.

(Continued from page 1186-adv. xviii)

"The suggestion, when brought out in the open, resolves itself into this: that when a county asks for admission of a patient, the hospital authorities suggest to the county authorities that they can make room for the new patient only on condition that the county authorities are willing to receive back and caré for in the county, one of their least troublesome, convalescent patients. Advice will be given by the hospital authorities to the county if they wish, of the best possible way

of earing for the convalescent patient, whether he should be boarded out with a family, whether he should be placed on a farm, as to what medical attention is necessary, etc. It will bring the state hospital in closer contact with the counties in its districts. It will necessitate psychiatric social workers in connection with the hospital in the future. It will be the first step in a program of mental hygiene in the hospital district.

"The proposition has considerable merit and should appeal to all thinking people."

INSURANCE OF MEDICAL CARE IN RHODE ISLAND

The House of Delegates of the Rhode Island Medical Society, meeting on May 18, considered the report of the National Committee on the Costs of Medical Care and then took the following action which is recorded in the July 1880 of the Rhode Island Medical Journal:

"It is the intention of your present Committee to continue its study and if possible formulate a scheme which under the control of the Rhode Island Medical Society shall provide adequate medical, nursing and hospital eare to families in the income group say between \$1,200 and \$3,000. Such a scheme would not include Workman's Compensation cases, contagious diseases, mental diseases, venereal diseases or tuberculosis. Such a scheme must include the right of every patient to choose his own physician.

"Studies have been made which show that (Continued on page 1188-adv. x1)

(Continued from page 1187—adv. xix)

the average yearly cost of medical care per capita in the United States is about \$30.00 Further it has been shown that 29.8 per cent of this is paid physicians in private practice and 23.4 per cent to hospitals, the remainder being paid nurses, pharmacists, etc. This makes the expense for physician and hospital \$16.00 per capita. On such a basis of facts it would seem possible for the Medical Society to devise a plan by which it could undertake to care for a group of 5,000, or better, 10,000 persons in the income group where illness is likely to be a catastrophe.

"In a family of three with an income of between \$1,200 and \$3,000, a cost of \$48.00 to \$60.00 per year for assurance of adequate medical care would not seem excessive. To devise such a plan requires study of the facilities in any community where it may be applied. Further, certain safeguards, as the personal payment for first calls must be set up. Also the period for which hospital facilities would be supplied must be studied."

WHY EAT CRANBERRIES?

Who doesn't relish rich red, tangy-flavored cranberry sauce? To the American people since the time of the Pilgrims, the tasty fruit has had a peculiar intangible appeal. Frosty September days usher in bright autumn colors and — cranberries. These latest of the season's berries lend color to the table and interest in the meal. They seem to prod jaded appetites into activity.

Since Colonial times the cranberry has been regarded as possessing certain health virtues, especially as a febrifuge (fever reducer) because of its cooling effect. However, it is only recently that this fruit has been proved to possess real nutritive value. Investigations extending over a period of three years at the Massachusetts State College demonstrate conclusively that cranberries are richly endowed with vitamin C. This is the vitamin which promotes growth, strengthens the blood vessels, and makes strong bones and teeth. As little as three cranberries a day, that is, about one-eighth ounce, sufficed to promote maximum growth and full protection from symptoms of scurvy in young guinea pigs over a 90 day feeding period. In this test all the

berries, the guinea pigs lived only 25 to 33 days.

Vitamin C is unstable and is often destroyed by cooking, stirring or straining. Would cranberries lose this Will o' the Wisp vitamin if made into sauce? Exhaustive feeding tests on whole-fruit cranberry sauces made from several recipes showed a retention of 80 to 90 per cent of the vitamin content of the fresh berries.

Other experiments carried on with white rats showed that the cranberry contained small but significant amounts of Vitamin A, the anti-infective vitamin. The latter is thus called because of its function in aiding the body to resist infections of all kinds. This vitamin is found in greatest abundance in cod liver oil. It is fully retained when cranberries are made into sauce or jelly.

Thus we see that we may not only enjoy the attractiveness and flavor of cranberry sauce, but at the same time we are helping ourselves to vitamins—and health.—Adv.

MEAD'S 10 D COD LIVER OIL IS MADE FROM NEWFOUND-LAND OIL

Professors Drummond and Hilditch have recently confirmed that for high vitamins A and D potency, Newfoundland Cod Liver Oil is markedly superior to Norwegian, Scottish and Icelandic Oils.

They have also shown that vitamin A suffers considerable deterioration when stored in white glass bottles.

For years, Mead's Cod Liver Oil has been made from Newfoundland Oil. For years, it has been stored in brown bottles and light-proof cartons.

makes strong bones and teeth. As little as three cranberries a day, that is, about one-eighth ounce, sufficed to promote maximum growth and full protection from symptoms of scurvy in young guinea pigs over a 90 day feeding period. In this test all the vitamin C which the animals had was in the cranberries. Without the cranber of the c

ELI LILLY LABORATORIES

Sodium Amytal by mouth is reported to be useful in stubborn insomnia, in the prevention of convulsions, and for the production of mental and physical rest in various acute and chronic ailments.

It is emphasized that under ordinary circumstances the advantages of Sodium Amytal can and should be obtained by oral use.

Sodium Amytal Ampoules for intramuscular and intravenous use are indicated in conditions in which oral administration is not feasible either because the patient is unconscious, as in ecclaspsia, status epilepticus, cerebral hemorrhage, or because he resists, as in delirium or manic psychosis, or because a very prompt action is imperative, as in the control of convulsions of strychnine poisoning, tetanus, or convulsions from the toxicity of local anesthetics. In such emergencies, the parenteral use of Sodium Amytal meets the need for

ation at hand.

Decision to use Sodium Amytal parenterally instead of orally or rectally, should be made by the physician in the individual case only after carefully weighing the advantages and disadvantages of the injection method.—Adv.

immediate relicf and permits effective

dosage adjusted to the desired response necessary to control the situ-

WHOOPING COUGH

Elixir Bromaurate (Elixir Gold Tribromide) is being used extensively in the treatment of whooping cough. Due to the definite sedative, antispasmodic and antibacterial action of Elixir Bromaurate, its scope of usefulness has been widened to include other spasmodic coughs as well as the cough of pulmonary tuberculosis. It has also been

found valuable in bronchial asthma,

chorea, migraine, and petit mal.—Adv.

COLUMBIA UNIVERSITY IN THE CITY OF NEW YORK NEW YORK POST - GRADUATE MEDICAL SCHOOL UROLOGY

Beginning January 2, 1934. Under the direction of Professor Joseph F. McCarthy

The course approximates 34 hours a week, and includes:

Demonstrations of urologic operations and diagnostic procedures; cystoscopy and endoscopy; operative urologic surgery on the cadaver; urographic studies and interpretation; pathology, bacteriology and biochemistry of genito-urinary diseases; newer methods of endoscopic revision of prostatic hypertrophy, etc.

The class is limited to ten. The seminar is a full time six months course.

For further information, address

BLOOD CHANGES IN INTESTINAL OBSTRUCTION

By DANA W. ATCHLEY, M.D., NEW YORK, N. Y.

Read before the Section on Surgery, at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

TT is my purpose to discuss briefly that part of the physiological response to intestinal obstruction which involves the water and salt equilibria of the body. It is no longer necessary to defend the assertion that alterations in these substances play an important role in producing the clinical condition with which we are so familiar. My emphasis on the chemical aspects does not imply that I either ignore or belittle the role of such other factors as hypothetical toxins, tissue necrosis or local circulatory disturbances. I do not feel that our present state of knowledge justifies one in engaging in a controversy as to the relative significance of the various components that unite to form the net result of intestinal obstruction.

There is no step in the advance of medical science during the past twenty years that is more encouraging than the increasing tendency to interpret disease processes in terms of underlying physiological dynamics. More and more we speak of clinical mechanisms rather than clinical pictures. By this approach we have learned that in many instances the primary etiology of a disease condition is not the direct cause of the more serious complications or even of death if it ensues. Successful treatment of the primary etiology may leave us with a patient who remains seriously ill until secondary physiological disturbances are controlled. The cause of death may not be due to the fundamental etiological agent, but to the physiological response of the individual to that agent, in many instances a functional rather than an anatomical response. And it is often true that the functional response is unusually susceptible to appropriate therapy.

There is no section of physiology more satisfactorily understood in this regard than electrolyte and water physiology. The contributions of many workers have clarified the processes by which the body maintains its fluid and salt concentrations at constant levels. Moreover, in a great variety of diseases the

sequence of events leading to a disturbance in water and salt equilibria have been studied and the resulting hypotheses have brilliantly survived the pragmatic test of therapeutic application, May I review a few of these diseases and indicate thereby the setting in which we place our concepts of the abnormal physiology

resulting from intestinal obstruction.

One of the first clinical conditions to receive sophisticated appraisal was cholera; in 1909, Rogers pointed out that many of the patients under his observation during an epidemic in the Philippines were tremendously dehydrated. If he had had the proper chemical facilities he would doubtless have been able to demonstrate a striking decrease in serum salts and water. I was much interested to find accidentally a statement over one hundred years old com-menting on the thickness of the blood in cholera. The mechanism of fluid and salt loss in a disease which causes profuse watery diarrhea needs no elaboration. Rogers found that the administration of intravenous salt solution greatly decreased his case mortality. Water and salt depletion in cholera cause a marked drop in blood volume, thus producing a state of shock. The prostration and circulatory paralysis once thought to be dependent on a toxin derived from the cholera bacillus has been proved to be due in large part to easily remediable disturbances in salt and water metabolism.

In the past ten years many other pathological states have been included in this group of diseases with secondary physiological problems. As insulin began to be used in diabetic coma, it was noted that certain patients continued their downward course long after glycosuria and ketone acid production had been completely controlled. Eventually these patients died with a normal blood sugar and blood bicarbonate. It was soon recognized that secondary and independent physiological processes are initiated by the acute diabetic state. A patient in such a state loses tremendous

quantities of water and salt and when it occurs, a fatal outcome is usually not due to overproduction of acid, but at least in part to the shock that follows rapid dehydration. We have been able to show in careful balance experiments at the Presbyterian Hospital that removal of insulin from a diabetic is followed by immediate and excessive loss of water and salt. This occurs with glycosuria alone, but is greatly augmented when acidosis developes. It requires very little exaggeration to say that death in simple diabetic coma is due to shock and need not occur if the physiology of the situation is clearly understood.

I would like to describe one more interesting example of this general pattern; again, more in the field of medicine than surgery. Dr. Loeb, in our clinic, has demonstrated recently that many of the symptoms occurring in Addison's disease are dependent upon the loss of sodium from the body. He has kept a patient with typical Addison's disease practically symptom free for many months by the addition of an excess of sodium choride to her diet. A few days on a salt poor diet has on two occasions caused a relapse to the picture of acute adrenal insufficiency. The similarity between this picture and that seen in other states dependent upon salt and water depletion needs no comment, although, of course, it would be unwise to affirm that the adrenal cortex has no function other than the control of sodium excre-

long believed that the was symptoms following extensive burns were related to the absorption of a toxin from the destroyed tissues. This conception is fading into obscurity as the profound effect of the serous exudation from the burned areas is more certainly appreciated. Decrease in blood volume with resulting circulatory paralysis is without doubt a most important feature in the dynamics of this serious accident to the organism. It is more reasonable to believe that the benficial effect of intravenous salt solution is due to the restoration of normal blood volume than that it is due to the neutralization of a toxin.

The surgeon should be particularly interested in that type of salt depletion which occurs when the secretions from structures associated with the gastro-intestinal tract are diverted to the surface of the body by such operative procedures as gastrostomy, duodenostomy, pancreatic fistula, etc. These secretions may contain as high a salt content as blood serum and if their loss is ignored it will lead to a clinical condition analogous to those that I have just described. The effect of proper treatment upon such a patient is often spectacular.

I have tried to indicate that there is a fundamental identity in the clinical and physiological responses to salt and water depletion, occurring in a variety of disease conditions without the slightest intrinsic relationship to each other. Prostration, low blood pressure, dehydration and ultimately, the state of shock with peripheral circulatory, rather than cardiac, failure, constitute this oft repeated clinical pattern associated with loss of water and sodium chloride (particularly sodium) from the body.

It is obvious that the typical case of high intestinal obstruction fits readily into this group. Hartwell in 1912 recognized the importance of dehydration, thus greatly advancing the therapy of this condition. workers have described the chemical alterations of the blood in high intestinal obstruc-However, the first analysis of the mechanism as a whole was made by Gamble in 1925. His carefully planned experiments included not only complete electrolyte analyses in the blood, but, also, detailed studies of the composition of the gastro-intestinal contents and vomitus. Gamble was able to prove that all the profound chemical changes occurring in the body fluids were dependent upon the loss of gastro-intestinal secretions. He quite properly emphasized the importance of base loss, principally sodium. As stated in the foregoing discussion, it is the loss of this component, i. e. sodium, which so seriously effects the individual in states characterized by electrolyte and water depletion. Our attention was focussed on the chloride ion for many years, for the simple reason that chloride analyses are easy, whereas sodium analyses are very difficult. Ingenious theories were elaborated with chlorine in the role of a protecting agent, neutralizing hypothetical toxins. seemed incompatible with theories knowledge, but they could not be disproved until it was possible to account for all the chloride loss by accurate analyses of vomitus and other excreta.

While it is possible to understand the serious effects of high intestinal obstruction upon the basis of sodium and water loss, there is present in pyloric obstruction another process which is somewhat different in nature. As you well know, gastric juice contains a high concentration of HCl so that an alkalosis is produced if vomiting is greatly prolonged. This secondary or perhaps tertiary physiological response to obstruction is easy to combat and probably is rarely responsible for a fatal outcome. Its essential symptom is tetany and it yields readily to therapy directed toward the salt and water depletion.

A uniform observation in high intestinal ob-

struction is the presence of an elevation of blood urea. This nitrogen retention has been explained in many ways. It was long considered a result of damage to the kidney by the toxins formed in the obstructed gastro-intestinal tract. Others assumed excessive protein destruction by the same toxins. Gamble suggested that the severe dehydration causes an alteration of renal function due to lack of available water for the kidney. Elevation of blood urea is a consistent observation in the various types of salt and water deplction that I have mentioned this morning. But, in addition to dehydration and more or less dependent upon it, we find in all of these conditions a tendency to the production of circulatory stasis and shuck. There is always a drop in blood volume and, as previously stated, the inevitable outcome of a rapid drop in blood volume is shock. The capillary stasis that accompanies shock affords a simple explanation for the temporary suspension of renal function, that causes nitrogen retention in these pathological states.

Lower intestinal obstruction is a process less clearly understood than high obstruction. The secretions of the intestinal tract remain within its lumen, increased pressure in the gut interferes with its blood supply, bacterial growth is present; indeed, so many other faetors are introduced that accurate appraisal is well-nigh impossible. However, no one can deny that salt and water depletion play some role in every case and must never be forgotten in planning therapy. It should be restated that an individual can lose tremendous quantities of water and salt into his gut and that as long as reabsorption does not take place, this fluid is as unavailable to the blood stream as if it had been vomited. Gamble was able to produce all the clinical and chemical disturbances of pyloric obstruction in rabbits. These animals do not voinit, so the lost water and salt simply accumulated statically within the stomach, whence it was removed by the experimenter at autopsy and accurately analyzed.

In summary, may I point out again that the chemical results arising from the secondary physiological effects of intestinal obstruction produce a pattern very similar to that found in several disease conditions fundamentally different, but having the common denominator of salt and water depletion. The mechanism of this depletion in intestinal obstruction seems to consist in the rapid removal of water and electrolytes (mainly sodium chloride) from the circulating blood, thence to be vomited, or to accumulate statically within the intestinal lumen. This sequence of events occurs in an individual to whom the ordinary routes of salt and water replacement are obviously closed.

The end result of such fluid and salt loss is peripheral circulatory failure with profound inhibition of all normal tissue activity. The elevation of blood urea that ensues is probably an expression of this effect upon renal tissue. The higher in the intestinal tract that the obstruction occurs the more completely does this mechanism dominate the picture. While it is probably safe to say that the clinical pattern of pylorie obstruction is wholly a result of these well understood physiological processes, the student of low intestinal obstruction finds a variety of disturbances wholly unrelated and combining to form a resultant clinical problem difficult to analyze. However, no matter what its relative value may be, this chemical component is always present and must be reckoned with when therapy is being planned. is obvious that the presence of tissue necrosis when the gut is strangulated is an additional force toward the production of shock.

Treatment of the phase of intestinal obstruction that has been the subject of my discussion is essentially a replacement therapy. Salt and water have been lost from the circulating blood, hence salt and water must be replaced therein. This should be done by the intravenous administration of adequate amounts of normal salt solution or Ringer's solution. I wish first to emphasize strongly the necessity for using salt solution rather than simple glucose solutions. It is impossible constructively to combat dehydration with glucose solutions; water cannot be retained in the body without its skeletal structure of salt, in fact, I have seen patients thoroughly dehydrated by the constant use of 10 per cent glucose solutions. In such patients the water could not be retained without sodium and the constant diuresis caused by the glucose and water washed out more and more salt, thus augmenting the salt depletion already accomplished by the intestinal obstruction. This is no academic point; theory and practical experience unite to warrant the statement that the use of glucose solutions alone in this condition as well as in any other state of dehydra-tion may be actually harmful. There is no more frequent and, in light of modern knowledge, more inexcusable mistake than this one. If glucose administration is desired, be sure that it is given in salt solution. In my opinion the nutritive effect of glucose is negligible, but it has a definite role in combating ketosis and should be used routinely in children and obese individuals. Ketosis is a complication to be avoided as far as possible because it also sets in motion a physiological response tending to salt and water depletion, as I pointed out when discussing diabetic coma. The ideal solution is 5 per cent glucose in normal saline,

because glucose in a 10 per cent solution cannot be oxidized rapidly enough in many instances, to prevent its action as a diuretic.

When I suggested the use of adequate amounts of intravenous fluids I meant literally adequate. We have been very timid in our use of intravenous therapy in these conditions. One need not fear overstrain on the heart from large amounts of intravenous fluid when the patient is suffering from salt and water depletion, particularly if the infusion is given with a 20 gauge needle. His rapid pulse and low blood pressure do not mean cardiac weakness He must but peripheral circulatory failure. be treated steadily until the evidences of dehydration disappear whether it be two liters or seven liters that are required. Our mistakes have practically always been on the side of too little rather than too large amounts.

The route of administration of salt solution should be exclusively intravenous when the dehydration is advanced and shock is a part of the picture. The absorption of water from the subcutaneous tissues and the rectum is far too slow in peripheral circulatory failure. The fluid must go into the vein directly and speedily. In mild cases or later in the course of therapy, intravenous drip, clyses and rectal taps may be employed, always using salt solution, of course.

My discussion has been confined to one of the secondary physiological effects of intestinal obstruction, viz., salt and water depletion. I have not attempted to appraise this complication in relation to the other known components of the clinical picture, simply indicating that the higher the obstruction, the more responsible it appears to be for a serious out-We are familiar with this mechanism of salt and water depletion as a serious complication in many disease conditions such as diabetic acidosis, diarrhea, severe burns and Addison's disease, and it always tends to result in a state of shock, with widespread inhibition of tissue activity. Therapy consists of the intravenous replacement of salt solution as rapidly as possible until it is evident that the complication no longer exists.

THE CAUSE OF DEATH IN HIGH OBSTRUCTION

By J. E. SWEET, M.D., NEW YORK, N. Y.

Read before the Section on Surgery at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933

THIS problem of intestinal obstruction has been actively before the profession for a good many years. The catastrophic character of the clinical picture has very naturally and very properly indelibly impressed itself upon the mind of every surgeon who has encountered a case. On the other hand the many changes involved in the body processes following an intestinal obstruction have excited the interest of laboratory workers from practically every laboratory field; with the result that an answer to the problem has been found in the field of bacteriology and in each of several of the branches of physiological chemistry, as, for instance, in disturbances in water balance due to the loss of water, in an upset in the acid-base metabolism, or acidosis, in the production of toxic products of digestion, and so forth. But the continued flow of papers upon the subject proves, if nothing else, that an answer acceptable to all the diverse interests involved, has not yet been forthcoming.

I sometimes think that much of the confusion which is evident in medical publications is because of the fact that many of the workers, particularly in special fields, are not familiar with the clinical picture as it occurs in human medicine, nor with the facts of human pathology. As I see it, all research work in medicine, no matter how abstruse, starts from the patient, and must,

if it is at all to the point, eventually revert to the patient. Thus, several things stand out, which have not always been borne in mind in research studies. First is the clinical similarity between acute pancreatitis and high intestinal obstruction, a similarity so complete that few experienced surgeons will venture a differential diagnosis. second clinical fact is that in both these conditions the picture of extreme shock is strikingly unlike the clinical picture of shock following the excessive loss of blood in one respect, namely, that the patient's mentality remains active, even hyperactive, to a time long past that at which the blood pressure reading would indicate an anemia of the brain. The first symptoms of loss of blood following a severe hemorrhage are exhibited by the brain; fainting, loss of consciousness. Clinically there is not in every case any great loss of water and salt from the body by vomiting; and conversely, there are clinical conditions, such, for instance, as Asiatic cholera, in which a much more pronounced loss of body fluid is not accompanied by any of the symptoms which characterize the picture under discussion.

In the experimental field there are two other conditions which closely simulate the picture of high obstruction. The one is acute anaphylaxis in the dog, the other is the condition produced by the complete removal of the adrenal glands.

To this group of four conditions which seem to result in a common ending may be added another more closely related finding in the experimental field. If the content of an obstructed loop is extracted with hot water, precipitated in an excess of alcohol, the precipitate again treated with hot water and reprecipitated with alcohol, a highly toxic product is obtained which, injected into a normal animal may reproduce the complete picture of obstruction. And if the intestinal eontent of an animal killed by this poison is treated in the same way a similar toxic product is found. And yet there has been no mechanical obstruction, at least, of the intestine; the possibility of a paralytic ileus cannot be ruled out. I say this toxin may produce death, because of two animals as nearly alike as can be chosen in every respect and injected with the same toxic dose, one may react but slightly, while the other may be dead within six hours.

My belief has therefore been, for a long time, that the pathological process in the pancreas, or in the intestine, is not in itself the actual cause of death, but that this process within the pancreas or the intestine starts off something in the body which, if excited to a sufficient degree, is the actual fatal process; and that this is why the operative relief of the primary difficulty as time elapses becomes less and less a curative procedure. The situation is comparable, I believe, to anaphylaxis, in which a very small dose of foreign protein sets off a fatal process in a sensitized animal.

A further experimental finding must not be lost sight of. If both adrenals are removed, the intestinal content will be found to contain the same, or a similar toxin.

There is no doubt that loss of water from the body aggravates the condition. There is no doubt that addition of water and sodium chloride is a life extending procedure. There is no question of the chemical changes in the blood which have been reported. There is, however, at the same time, I think, a fair question as to how many of these changes are primary and how many are secondary or symptomatic. The fundamental trouble seems to lie in the problem of the water balance of the tissues themselves. Perhaps it would make it elearer to consider it a condition the exact opposite of diabetes insipidus. In diabetes insipidus a lesion of some portion of the brain base, that portion of the floor of the third ventricle known as the hypo-thalamus, or of the pituitary itself, results in such a disturbance of the entire body that the cells can no longer hold their normal content of water. The result is an excessive output of fluid from the kidneys and the effort to compensate by excessive water intake, i.e., excessive thirst. The condition before us presents the opposite picture, the body eells are evidently taking up more than their normal sup-ply of water. The fluid volume in the blood vessels is therefore diminished, the blood is thickened, substances which should normally be excreted pile up in the blood, such as the non-protein
introgen. And because the blood salts are involved in the process, either primarily involved,
or merely because they are dissolved in this water,
the blood salts are disturbed and the acid hase
relationships are upset. The addition of fluid
and sodium chloride will undoubtedly help such
a condition, but I still feel that it does not follow
that the loss of water and salt is the primary and
causal factor.

We must seek this factor in the fundamental mechanism which performs the opposite function to the function of that portion of the hypo-thalamus or the pituitary which seems to control the passage of water from the tissues. All the functions of life are effected by a balancing of two forces, one exciting, one inhibiting. From the recent work upon the adrenals it seems to be conclusively shown that perhaps the main function of the adrenals is to preserve the water balance of the tissues by balancing the action of this center in the hypothalamic region. The center in the brain normally keeps water in the tissue or normally counteracts the adrenal function of withdrawing water from the tissue. When the brain control is gone, the adrenal function eauses water to be withdrawn in excess, when the adrenals are gone the brain center functions to exeess, water is drawn from the blood stream into the tissues to the extent of so called shock.

Such an idea would explain the value of sodium chloride which, by its osmotie action would tend to withdraw water from the tissues.

In this disturbance of water balance may lie the explanation for the difference which is to me so striking in the function of the higher centers in the primary shock following severe hemorrhage, and in this secondary shock under consideration. The brain function would presumably be disturbed by a loss of water from its cells as readily as by an anoxemia. In post-hemorrhagic shock, with intact adrenals, the water supply of the brain cells is exhausted by the body's effort to obtain the proper blood dilution. In this toxic shock, the water supply of the brain cells is at least maintained if not increased; hence, if merely maintained, a continuation of normal brain function, if increased, perhaps the explanation of the hyperactivity.

But perhaps, above all, there would lie in such an explanation of the processes underlying such a clinical picture, the reason for the clinical indication which becomes daily more clear, early operation before the process shall have produced irrecoverable damage to the adrenals.

The idea of a relationship between the adrenals and intestinal obstruction is to me, at least, by no means a new thought. In a paper read in 1912 the problem was discussed with particular atten-

tion to the similarities in the symptomatology of acute pancreatitis and high obstruction. In this paper I noted:

"One of the most constant pathological findings in our work has been an extensive destruction of the adrenal glands following intestinal obstruction, a picture of an acute necrosis affecting chiefly the medulla.
"The most typical symptom of the conditions I have

grouped together is the collapse and shock. Now shock is not a clinical entity. There is a shock due to central influences and there is a shock due to purely peripheral conditions. I believe the adrenals to be engaged in maintaining blood pressure by the control exercised by the specific adrenal products over the arterioles of the periphery. I believe I am right in the assumption that the shock of these abdominal conditions is a shock in which the blood pressure primarily falls. The centers, as evidenced by the continued functioning of the higher centers, are not primarily affected. After the shock in-duced by severe hemorrhage there comes first the evidence of the anemia of the higher centers, fainting and loss of consciousness. In peripheral shock the centers would remain intact until the blood pressure had fallen to a degree which would cause central anemia.

"Because the absorption of pancreatic ferments has been shown to be the cause of death in acute hemorrhagic pancreatitis, because the clinical picture of acute obstruction of the upper bowel so closely resembles that of acute pancreatitis; because the loss of the normal functions of the adrenals would explain the most striking symptoms of these conditions, the collapse and shock, and the adrenals are found to be seriously damaged in intestinal obstruction; because of the relations between the pancreas and adrenals, I conclude that the cause of death in acute hemorrhagic pancreatitis, in high intestinal obstruction and in post-operative ileus is the absorption of pancreatic products by causing destruction

of normal adrenal activity.
"I would ask your pardon for presenting an evidently unfinished paper were it not for two things; first, the final proof of my supposition demands methods and reactions not yet discovered—we are treading beyond the limits of our present knowledge."

Since the above was written, the work upon the adrenals which has been but recently published by Swingle and his collaborators² has supplied these methods and reactions not discovered in 1912, and has established the similarity between the symptoms following adrenalectomy and the symptoms of secondary shock. Some of the conclusions reached by these authors are as follows:

"(1) The function of the adrenal cortical hormone is the regulation and maintainance of a normal circulating volume of fluid within the vascular system. In the absence of the hormone, fluid is continually lost from the circulation presumably by transudation through the capillary walls, with the result that the adrenalectomized animal is unable to maintain his normal blood volume, and eventually dies from circulatory collapse due to insufficiency of circulating fluid.

(2) Accompanying the progressive decrease in blood

volume is a progressive fall of blood pressure to the death level. The decline in arterial pressure is appar-

ently a direct result of the decreased volume of circu-

lating fluid.

"(7) The blood-urea and non-protein nitrogen also vary inversely as the blood pressure. The decreased renal function, so evident during adrenal insufficiency, we attribute to the changes in circulation previously mentioned, i.e., diminished blood volume, decreased pressure, and presumably, therefore, to decreased filtration pressure and blood flow in the kidney.

"(11) It is our opinion that all the manifestations, symptoms and physiological peculiarities, which have been described as occurring in adrenalectomized animals are merely results of a progressively falling circulation due to decreasing volume of circulating fluid, in an animal which is unable to compensate (as do normal animals) for its low blood volume and blood pressure by

dilution

"(12) The striking similarity between the symptoms of adrenal insufficiency and those of traumatic or secondary shock, as reported in the literature for man, is too obvious to be ignored. The cardinal features of traumatic shock are likewise the cardinal features of adrenal insufficiency—viz., the depleted blood and plasma volume, lowered arterial pressure, hemoconcentration and inability to dilute the blood (uncompensated human cases). The really essential point in secondary slock is failure of the blood-diluting mechanism and loss of power to increase the blood volume. This is also the primary cause of the symptoms of adrenal insufficiency."

When I have weighed all the evidence which I have but briefly outlined here, I come to the conclusion that the cause of death in high intestinal obstruction is adrenal failure. You may say this is but begging the question, merely changing it so that it now reads, "what is the cause of the cause of death in high obstruction." I grant this, but I might point out that an explanation of the complex changes which occur in the body, the loss of water, the loss of sodium chloride, the blood concentration, the increase in non-protein nitrogen and so forth, and so forth, being offered by the loss of the function of the adrenals in controlling the water balance of the body, leaves us, perhaps, more free to pursue the essential problem.

I am personally satisfied that a toxic substance perhaps histamine-like, not normally found in the intestinal tract arises under the conditions of obstruction—that this toxin injures the adrenals, but the intestine of an animal after bilateral adrenalectomy without obstruction seems to contain the same toxin. A vicious circle is set up in which the greater the injury to the adrenal, the greater the production of toxin. Therefore, unless the removal of the primary cause, namely the relief of the obstruction be carried out before the adrenals are too far gone, this vicious circle between the adrenal and the intestine may continue. with the result that the operation accomplishes no

purpose.

DISCUSSION OF PAPERS OF DOCTORS ATCHLEY AND SWEET By SAMUEL STANDARD, NEW YORK CITY

WE have here two papers both dealing with the same subject. Both are concerned with a cause of death, both look for this cause beyond the field of involved intestine to some secondary factor or factors ultimately responsible for death. Both postulate a functional death arising from a precedent organic derangement. Although traveling along the route of a common idea, each finds his destination remote from the other. Doctor Atchley adhering to factual findings in the blood chemistry during the progress of the disease following it in its development, its maintenance, and its subsidence finds, he believes, sufficient evidence to determine the functional derangement of the disease, a method of controlling this derangement, and an explanation for death.

Doctor Sweet recognizing a common clinical syndrome in intestinal obstruction, acute pancreatitis and bilateral adrenalectomy, assumes a common etiological factor, namely,

adrenal insufficiency.

Since Doctor Sweet's deductions are elinical, we most look to post-mortem findings for evidence of adrenal injury following death from intestinal obstruction. We have had none on the Third (New York University) Surgical Division at Bellevue Hospital. The assumption of a common etiological factor because of a clinical similarity is always a dangerous one. A well known example is the common syndrome associated with increased intracranial pressure which, however, gives us no clue as to the underlying pathology producing it. To postulate a toxic substance of unknown origin with the difficulties involved in proving or disproving it, leaves no open path for progress. It appears much safer to work on factual findings today, and if, ten years from today these are found to be wrong our change of opinion would constitute so much progress.

The changes in blood chemistry that Doctor Atchley mentions do occur. They are obvious with marked vomiting, and where vomiting

does not occur, Gamble has well explained the loss of fluid base and chloride by the presence of unabsorbed fluid within the intestinal tract which for physiological purposes is beyond use because it cannot be absorbed. The acceptance of the disturbance in salt and water metabolism as a basis for the clinical syndrome in intestinal obstruction offers less perhaps diagnostically than therapeutically. Our present knowledge in bio-chemistry is insufficient to apply quantitatively to complex reactions within the body. Our explanations, therefore, for the fall of chloride, fall of base, rise in non-protein nitrogen and loss of fluid may be considered incomplete. However, the fact is that these findings do occur and the more important fact is that if we replace these losses clinical improvement follows. I should like to stress the point that Doctor Atchley also emphasized, that the body cannot retain water without salt. This is an important concept in the parenteral replacement of fluids,

With an intact renal function the kidney may be expected to select for retention or excretion those substances needed or not needed by the body provided a sufficient amount of water is available for adequate urinary volume. On this basis Hartman and Ellman have suggested the use of their "combined solution" which may be administered in alkalosis or acidosis leaving it to the kidney to achieve and maintain the homeostatic equilibrium in the

blood stream.

It is a significant indication of the general trend of surgery to have this section on surgery opened with a paper dealing with fundamental physiological concepts in blood chemistry and in endocrinology. It arouses the thought that the surgical patient is being considered more and more as a complete physiological problem, with a short interim of the surgical procedure as part of his treatment. The time before entering the operating room and after leaving it is taking on the importance it deserves.

THE TREATMENT OF INTESTINAL OBSTRUCTION By JOHN J. MORTON, M.D., ROCHESTER, N. Y.

From the Department of Surgery, the University of Rochester School of Medicine and Dentistry, Rochester, New York, Read before the Section on Surgery, at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

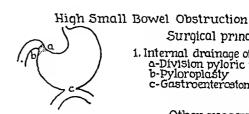

ANY surgeon can be rightly proud of a low mortality rate in his operations for intestinal obstruction as it is a testimonial to his diagnostic ability, technical skill, and surgical

judgment. There is no condition which calls for more critical analysis of symptoms and signs in order to arrive at an early diagnosis. There is no surgical problem which demands more versatility in the technical handling of it. And finally there is no place in surgery where correct surgical judgment gives a response more surely; or where faulty judgment is more certainly followed by disaster.

The treatment of intestinal obstruction can be divided into that for the mechanical forms i.e., high small bowel obstruction; low small bowel obstruction; strangulation obstruction; and obstruction to the large bowel; and that for the paralytic type of obstruction.

The high small bowel mechanical obstructions are well illustrated by the complete blocks at the pylorus as noted in hypertrophic stenosis in the new born, or the obstructions to the stomach in ulcer or cancer. These conditions are associated with dilatation of the stomach; persistent vomiting with loss of fluids and essential salts, leading to dehydration, demineralization, and to shifts in the acid-base balance of the body, either toward an alkalosis or an acidosis. There is also a deficiency in absorption of foods which causes depletion of the energy storehouses of the body and undernutrition. The problem in these cases is to provide internal drainage for the dilated viscus; to restore the loss of water and salts to normal. levels; to bring about equilibrium in the acid-base balance; and to supply quickly absorbable energy producing food stuffs. Internal drainage of the stomach can be obtained by division of the pyloric ring, by some form of pyloroplasty, or by a gastroenterostomy. The mere internal drainage of this viscus will help to restore the water and salt balance, but studies of the blood chemistry will give valuable information in regard to the special needs in a given case. Normal physiological saline, Ringer's or Hartmann's solutions can be introduced into the body by several different These normal solutions are much to be preferred over any hypertonic intravenous medi-However, sodium chloride salt can be supplied rapidly by giving a 2% solution by hypodermoclysis or a 3% or 5% solution intravenously. Intravenous hypertonic solutions such as this should be given very slowly—500 cc. of 5% solution should take over one hour to administer. Also since an increased secretion into the bowel and an active stimulation of peristalsis results from such medication it should never be used until the viscus has been decompressed. To supply nutrition in an easily assimilated form a 25% solution of glucose intravenously is probably the most useful method. 250 cc. of a 25% solution can be injected every 4 to 6 hours, taking about one hour for each treatment. If given more rapidly a portion is lost in the urine. Glucose can be given by proctoclysis in 5% solution although there is a dispute as to whether it is completely absorbed by this route. In some cases it may be necessary to give glucose subcutaneously. can be done in a 2% solution. Glucose should al-

ways be given with saline and usually also with By itself, it inhibits peristalsis, pulls fluids from the tissues into the blood, and causes stimulation of the kidneys to increased output of salts and water, all of which effects are harmful. (See Figure 1.)

The low small bowel obstructions differ from the high small bowel obstructions in the fact that the small bowel is suspended on a mesentery which may at any time lead to partial strangulation by twisting or kinking. In this sense a low small bowel obstruction can refer to any loop from the ligament of Treitz to the ileo-cecal valve. This condition is associated with distention and dilatation of some loop or loops if seen early, but usually by some dilatation all the way to the duodenum as the early diagnosis is rare. Distention in itself is accompanied by diminished absorption, increased secretion, and slowing or stoppage of the circulation through the loop. There results thus a loss of fluids and essential salts varying with the amount of vomiting or with the amount of dilatation of the loops with their trapped secretions. A large quantity of fluids and salts can be stored in these hugely dilated loops and it is just as much lost to the patient as if it had been vomited. Demineralization, shifts in the acid-base balance, and deliydration may thus be expected in these cases. There is also an upset in the nervous mechanism which is not yet clearly understood. In the late stages of these obstructions frequently there are areas of focal necrosis in the bowel wall which theoretically can expose the capillary bed to poisons within the loops. The patients, too,

certainly appear toxic in the later stages but the evidence for a toxin is as yet meagre. The problem in these cases is to decompress the distended loops; to restore the salt and water loss; to reestablish the acid-base equilibrium; to replenish the food energy reservoirs; to return the bowel to its normal functions; to compensate for the plasma loss from the blood; and to overcome the toxaemia. Decompression of the distended loops can be brought about in a number of ways, but of the first importance to the surgeon is a definite orientation so that he does not fumble about first in one direction and then in another. To get orientation in a small bowel operation, it is necessary to start at some fixed point. The ligament of Treitz and the ileo-cecal valve can serve this purpose. The surgeon thus can either start above and trace down the distended bowel, which is the method usually taught. Or he can better start below and trace up the collapsed loops. avoids trauma to the distended loops, makes for little handling of them, and brings the operator quickly to the lowest obstructed point. The distended bowel can be decompressed by release of the obstruction in the majority of cases. In complicated multiple obstructions a lateral anastomosis around the obstruction between a distended and collapsed loop is often the simplest and best solution. Low enterostomy with slow graded decompression has been recommended in the late cases, the tube being alternately clamped and released for withdrawal of small amounts of material. After a period of such treatment when the patient's condition has improved the obstruction can then be managed surgically with more safety. In my opinion this step is very seldom necessary because in the late cases there is always some degree of paralytic obstruction as well and even when the obstruction is released it may take two or three days for the distention to subside, thus in essential preserving the principle of a graded decompression. High enterostomy in the upper iejunum has also been advocated. We believe that this part of the intestine can be just as effectively handled by an inlying duodenal catheter kept in place or replaced from time to time as necessary. Enterostomy below the obstruction for the introduction of therapeutic solutions can at times be employed. Introduction of salt solution and glucose in sufficient quantities as discussed previously will serve to do almost everything else that is necessary. Blood transfusion also is very valuable for bringing about more normal blood relationships and for counteracting the shock and toxic symptoms. The restoration of the bowel to its normal activities can usually best be left to its own natural return of function. This point should receive emphasis, too much forcing or tampering on the part of the physician often produces more harm than good. In case that the peristaltic action does not seem likely to return perhaps the best stimulation we have is

the intravenous injection of hypertonic salt solution, 20 cubic centimeters of a 10% sodium chloride solution being used. This should take five minutes to administer. It can be repeated two or three times if necessary. A larger hypertonic sodium chloride solution can be employed if the blood chlorides are much reduced. In such a case 500 cc. of 5% sodium chloride can be given intravenously over a one hour period. The application of heat to the abdomen is often very useful in promoting peristalsis. It can best be applied by electric light and cradle. At times hot stupes or hot water bags or an electric pad will serve the purpose but all these must be carefully watched by the nurse. All food and fluid should be withheld by mouth until normal peristalsis has been resumed. It is often useful to leave an inlying duodenal tube to keep the stomach and upper bowel decompressed and to save the patient from vomiting until the normal peristaltic activity is reestablished. As far as drugs are concerned we believe, that in most cases the more drastic stimulants do more harm than good. On rare occasions small doses of physostigmine or eserine may be of help. Morphine should be discontinued as soon as possible after operation as it may cause diminished and even reversed peristalsis in some patients. A mild cathartic such as milk of magnesia or citrate of magnesia is often serviceable after the reaction to operation has subsided. Mineral oil may also be used to advantage during this same period. In late cases of obstruction, there is so much derangement of the normal relationships of salt, plasma, and fluid balances or perhaps toxaemia, that there is often little that we can do to change the picture. The patient is already overwhelmed by these changes when he is first admitted and as far as medicine is concorned he is too late for help. (See Figure 2.)

Strangulation obstruction requires early diagnosis if anything is to be accomplished. Fortunately, the strangulated hernia is usually being recognized early enough by the profession and by the laity. The internal strangulations, on the other hand, still furnish a good share of fatal In strangulation obstruction the great danger is necrosis, gangrene, rupture and peritonitis. There is also supposed to be absorption of toxins from the strangulated loops. There is very little change in the chemistry of the water and salts of the blood but the non-protein nitrogen may be high. There is a decided fall in blood volume and loss of blood plasma into the loops The surgical problem in all in some cases. strangulation obstructions is to release as early as possible the strangulating mechanism. If the circulation returns into the bowel no further surgery is necessary except repair of the wound. borderline cases, past experience often is of the greatest assistance to the surgeon in judging the viability of the bowel. In case there is no evidence of returning circulation or in case of doubt it is safer to resect the gangrenous loop well beyond the damaged tissue and then perform an immediate end to end anastomosis. The anastomosis can be made safely in bowel which has a normal glistening appearance, a good circulation, and an active response to stimulation. Accurate placing of the sutures into the submucosa, with a minimum of diaphragm at the anastomosis and approximation of serosa to serosa are essentials in the technic of this procedure. The anastomosis can be made by the closed (Parker-Kerr basting stitch), or open methods, and silk is the suture material of choice. When the condition of the patient is critical, the gangrenous bowel can be exteriorized and an enterostomy performed above the damaged loop. After the condition has improved, a later operation can be done more safely. In theory this manoeuver should be useful but in practise it seldom is. Focal

necroses can be turned in under mattress sutures. Supplementary therapy in strangulation obstruction consists in restoring the plasma volume and in combating the toxaemia. The plasma volume is often markedly diminished. It is best restored by transfusion. When a donor is not readily

available the next best measure is to supply glucose and salt solution. There is usually no change in the blood chlorides in strangulation obstruction and there is no necessity for treating for dehydration, demineralization or changes in the acid-base balance. No specific therapy has been devised for the treatment of the toxaemia which is assumed to be present in these cases. (See Figure 3.)

Obstruction to the large bowel varies considerably with the location of the obstruction. In cancers of the cecum and those of the rectum complete obstruction is rarely observed because it is over-shadowed by other symptoms before it reaches that stage. Profound anemia, weakness, loss of weight and strength, a palpable mass and bleeding from the bowel, all serve to call attention to some major disease process. The obstructions in these types are usually only partial for this reason. It is surprising, also, how small a lumen may remain through these growths without evidence of complete obstruction. In contrast, the annular, napkin ring carcinomas of the transverse colon, of the descending colon, and of the recto-sigmoid junction often give rise to complete obstructions. The principles of the treatment of obstructions to the large bowel from other causes do not differ from those for carci-Volvulus, an exception, should be considered as similar to strangulation obstruction, and should be treated accordingly without fur-

In a complete or nearly complete obstruction to the large bowel there will be distention and stasis in the bowel above the obstruction, backing up of material in the small bowel, loss of appetite, failure to assimilate food; loss of weight and strength; and often anemia and infection when an ulcerative lesion is present. The surgi--cal problem is first to decompress the distended bowel above the obstruction. This can be done either by an external opening,—cecostomy or colostomy; or an internal anastomosis around the lesion,—ileo-colostomy or colo-colostomy. If the condition which caused the obstruction is inoperable, a permanent external or internal colostomy is all that can be offered. A permanent external colostomy should be as simple as possible in its execution. It can be placed in the left external rectus muscle about one inch below the level of the umbilicus; or through a small oblique incision half way between the anterior superior spine and the umbilicus, when the obstruction is in the rectum. If the inoperable obstruction is elsewhere in the large bowel, an internal anastomosis around it can always be performed and is preferable. Patients should be given instruction in the care of a permanent colostomy as it will make a great difference in their comfort. Following operation the colostomy opening should be irrigated daily so that it may be cleansed and free from irritation. With care the bowel can be trained to have

one evacuation daily so that a small dressing ean then be applied without elaborate apparatus Some patients prefer to empty the colon by an enema every morning, and can thus be sure of freedom from discomfort during the day elastic webbing band, as it gives with the motions of the body, is important in maintaining the dressings accurately and snugly over the colostomy opening If the condition is operable, the next problem is to build the patient up by high caloric foods, liver extract, iron, and transfusion, as necessary There is no hurry about getting these patients ready for the next stage of the operation which usually means a resection of the diseased bowel segment A mild cathartic and rectal irrigations twice daily with warm saline will serve to keep the large bowel well emptied and will allow infection to subside Mixed vac cines of streptococci and colon bacilli have been advocated by intraperitoneal injection 72 hours before operation We have not had enough experience with this procedure to be sure of its It is certain, however, that once the peritoneum has been infected in a preliminary operation the patient acquires a decidedly enhanced resistance to subsequent procedures. The bowel usually in such cases can be opened with impunity as the peritoneum will care for considerable soiling without trouble. Resection can be either primary with end to end anastomosis, a two or three stage Mikulicz procedure, or modifications of the above The dangers from any anastomosis in the large bowel are leakage from the suture line, fistula, and peritonitis For these reasons the ex-

ternal types are preferred as safer by most sur geons The internal anastomoses can be walled off by introducing drains to the neighborhood or by plastic procedures with the omentum about the suture line Surgeons of large experience can be so unorthodox as to do a primary resection with immediate anastomosis without a preliminary or any other colostomy, but this is unsafe for the

average man The convalescence is likely to be over a long time in all cases Transfusions after operation and general tonics are indicated (See Figure 4)

Paralytic obstruction from any cause is associated with dilutation of portions of or of the whole gastro intestinal tract. There is no peristalsis present, the secretions accumulate, distention increases, respirations become embarrassed, the pulse gets weak and rapid, and symptoms of shock appear The problem in these cases is to make the controlling nervous mechanism function As far as surgery is concerned there is nothing to offer except enterostomy which ordinarily is a futile gesture. The therapy consists in trying to stimulate peristalsis. This is helped by reducing distention of the upper abdominal gastro intestinal tract by introducing a duodenal tube and leaving it in place for siphon drainage. This also relieves pressure on the diaphragm and eases the respirations Enemas of various types and rectal tubes may take away the distention of the lower bowel Heat should be applied to the ab The patient should be moved about frequently, rolled from side to side, or even made to lie on his abdomen These shifts in position are sometimes useful Hypertonic salt solution, pituitary extracts, eserin and other stimulating drugs may at times be of use but just as often may eause a deleterious reaction Spinal anesthesia occasionally brings about an almost miraculous relief It should not be used for toxic paralytic obstruction or for patients who are in criti-The only difficulty with spinal cal condition anesthesia is in predicting what it will do There is no way to judge this and consequently we are always uncertain as to the result until it is actually tried Splanchnie anesthesia, a more ideal procedure, requires considerable skill and practise in its application Consequently it is ruled out for the average clinic. Fluids and salts can be supplied as necessary subcutaneously or intravenously (Se Figure 5)

The choice of anesthetic is important. If possible the inhalation anesthetics should be avoided in the average patient. Ether may cause retching and vomiting at the time of operation or follow-This is a reversal of the gradient of intestinal motility. The danger of aspiration during operation is a real one. There may also be hypoventilation of the lung bases following operation but this can be minimized by rebreathing carbon dioxide at the close of operation. Ether is also recognized as dangerous in the shock states although in small doses it stimulates the cardiac output. In early cases of obstruction it can be used to get relaxation. Nitrous-oxide-oxygen and local anesthesia will often be of service. Spinal anesthesia gives excellent relaxation, and would be ideal if the fall in blood pressure could always be effectively counteracted. Ethylene and nitrous oxide-oxygen alone do not give sufficient relaxation, requiring much more handling of the bowel when they are employed. Avertin gives a drop in blood pressure and insufficient relaxation unless supplemented by local infiltration. Local

abdominal block is excellent in some instances Hyperventilation should be a routine following operation no matter what anesthetic has been used.

Finally, surgeons should take into consideration prophylactic measures against intestinal obstruction whenever a laparotomy is performed. The peritoneum should be handled gently and large crushing bites with curved clamps should not be taken to expose the peritoneum for closure. These injuries cause necrosis and invite adhesions with the small intestinal loops in their neighborhood. The peritoneal closure should be accurate in as thin a line as possible. Drains, when they are used should not be carried across the small intestinal loops but should be led out by lateral stab wounds. Omentum should be utilized to cover in any raw areas to which small intestine might adhere. Amphetin, which has been advocated intraperitoneally for the prevention of postoperative adhesions, has not proved satisfactory in our clinic for those patients who have a tendency to repeatedly obstruct.

Discussion

Dr. Alexander Nicoll, New York:

In all types of obstruction the distention of the stomach by fluid contents is a matter of grave danger. Dr. Morton has pointed out that these fluids—toxic or not—have already been lost to the organism; their mere presence in the stomach and upper intestine is incredibly shocking to the patient, and the response of the patient to their removal is always definite, and frequently remarkable; the place for them is OUT. An indwelling duodenal tube is excellent provided the patient can accommodate himself to it-and provided close observation of its patency is possible. Frequent gastric lavage for the patient in whom the duodenal tube is ill borne is often a life saving method of treatment in the first 48 hours after operative relief of the obstruction. ever method is used the stomach MUST be kept

I believe that these patients suffer from a real toxemia, and to combat this condition and supply both fluids and salts it is my feeling that the use of normal saline is without superior; there is no way to compare with intravenous infusion, and the addition of glucose to the saline appears to be relatively unimportant; when glucose is used it should be balanced with insulin. Normal saline by the intravenous method is my first love, I am wedded to it—and remain faithful.

In speaking especially of small intestine obstruction Dr. Morton recommends approaching the obstructed point by the method of tracing upward the collapsed loops. This is quite contrary to the usual procedure, and has such obvious advantages that I want especially to thank him for a valuable suggestion.

In the matter of obstruction with strangulation I would like to add a word of extreme conserva-Resection is to be avoided if at all possible, for two major reasons: (1) the patient is in the poorest possible condition for extended surgical procedure and (2) resection of bowel loops which seem to be thoroughly devitalizedif not actually necrotic—is frequently not necessary. The power of Nature to repair dull, thick, flabby, inert loops of intestine in hernial sacs containing cloudy fluid of foul odor has been demonstrated to me a sufficient number of times to make me feel that when the surgeon is faced with a situation in which the pathology is such that the balance for and against resection appears even—it is well to remember that Nature has been doing some remarkable repair work much longer than any of us have.

In regard to large bowel obstruction: We see a class of case in this city—perhaps especially in the city hospitals—admitted with definite intestinal obstruction, in patients past 45, in which it seems probable that the obstruction is due to carcinoma of the large bowel. The patient has been too long without medical attention and it is obvious that no more than a palliative colostomy may be done. It is the custom on some services to proceed to a simple colostomy without formal exploration. I think this is a mistake and that in the long run it is wiser rapidly to explore under spinal anæsthesia in order that the future treatment of the patient may proceed based upon a diagnosis more definite than that of mere intestinal obstruction.

Concerning anæsthesia, I would like to quote

Doctor Morton verbatim, 'The only difficulty with spinal arresthesia is in predicting what it will do". My orders, at the moment, on my Division at Fordham Hospital, are that spinal anæsthesia shall be used only when there is a definite contraindication to the use of inhalation an æsthesia. In spite of my distrust of spinal anæsthesia, and my fear of it—which I acknowledge—I believe that it is well used in intestinal obstruction—other than that due to strangulated

lierma The perfect relaxation which spinal an asthesia gives makes exploration easy, quick, and gentle and permits good closure of the operative wound with minimum extrusion of intestines and resultant replacement trauma. The ideal anses thetic lies in the future it will, perhaps combine the pleasant and gentle induction of avertin, the perfect relaxation of spinal, and the safety of other

THE NON-OPERATIVE TREATMENT OF RENAL PATHOLOGY

By HENRY G BUGBEE, M D , NEW YORK, N Y.

I resented before the New York County Medical Society, May 1st 1933

THE treatment of kidney pathology is so closely associated with the etiology, pathological changes, symtomatology, and diagnosis, of renal lesions, that even an outline of treatment directed toward its relief would be inconsistent, were not, at least, a brief reference made to these aspects of the subject

The structure and function of the kidneys are such as to render them particularly susceptible to pathological changes, and especially to infections. Composed of minute tubules of great length and tortuosity, their secretory filters lying in close apposition and surrounded by a dense network of fine capillaries, the kidneys are called upon to climinate the waste products of the body in health and disease

From their anatomical position in close relation to the abdominal viscera and peritoneum, with their intimate blood, lymphatic, and nerve supply, and the association of urinary with other body functions (especially of the circula tory, respiratory, and gastro intestinal sys tems) they are susceptible to a variety of pathological changes which are not always detected, correctly diagnosed, and easily treated Pathology in other parts of the body may give rise to symptoms referable to the urinary tract, and renal pathology may cause symptoms in other parts, so that the kidneys must be borne in mind in treating any con stitutional disease studying distant pathol ogy, and the various disturbances of body function

Pyogenic Infection

The more important symptoms which lead one to suspect kidney pathology, are pain, local tenderness, disturbances of urinary function, pyuria, hematuria, bacteriuria, and the presence of an abdominal tumor

The most common type of renal pathology

is that due to pyogenic infection. That infections of the kidney are not more common is, in part, due to the fact that the kidneys, through the endothelial cells of the capillaries, possess a remarkable phagocytic action by means of which they dispose of large numbers of bicteria

Much recent experimentation his been car ried out with the object in view of ascertaining as to whether the healthy kidney climinates bettern, and the observations of Helmholz and others who injected animals with various bettern, — colon, streptococcus, stephylococcus and virdnis—recovering the urine from the bladder with a pipette, through a suprapuble cystotomy, after searing the bladder wall, showed that bacteria were not present in the urine from healthy kidneys, although colonies were found in the glomeruli and in the capillaries between the tubules, thus sustaining the results of experimentation carried out by earlier investigators

An overwhelming dose of bacteria may reach the kidneys, and give rise to an acute bilateral infection, but contributing causes are often necessary to produce kidney infections most important of which are obstructive in terference with the outflow of urine at any part of its course, general and focal infections, trauma congestion from exposure, and the

presence of a foreign body

Any infection, local or general, may be a contributing factor, the injection, intravenously, of organisms obtained from abscessed teeth have produced kidney infection while infections of the tonsils sinuses, and the presence of boils and carbuncles have frequently been noted. Following the influenza epidemic of 1918, the writer reported a series of cases of acute pyelonephritis secondary to this infection. A lowering of resistance in the kidney with the introduction of bacteria seems to be

the requirement, rather than a specificity of

certain bacteria for kidney tissue.

Investigations have shown that the colon bacillus is the most frequent cause of renal infection, being present in from 60 to 89 per cent of all cases, either alone, or associated with other organisms. It is found in an acid, occasionally neutral urine, appears in a variety of forms, and may produce a mild bacteriuria or complete destruction of kidney tissue. Staphylococcus aureus and albus are next in order of frequency, followed by bacillus proteus vulgaris, typhoid, streptococcus, gonococcus, pyocyaneus, and influenza.

While bacteria may gain entrance to the kidney by the ascending route, i. e., through the ureter, often aided by bladder reflux; or by the ureteral lymphatics; by direct extension from the bowel or inflammatory foci; or direct extention from the bowel through the lymphatics; nevertheless the most common mode of infection is descending, or through the blood

Cocci infect the glomeruli, producing suppurative areas with cortical abscesses which may even extend outside the kidney with the formation of a perinephritic abscess; while, in colon bacillus infections, the organisms are excreted into the tubules and extend into the pelvis spreading the infection and rapidly appearing in the urine.

Types of Infection

The most common types of renal infection may be classified as acute and chronic pyelonephritis, infected hydronephrosis, and pyonephrosis; other less common and more severe types are acute pyaemic kidney, focal suppurative nephritis, infected infarcts and carbuncles.

In acute pyelonephritis, the organisms, in the majority of instances, gain entrance through the blood stream, give rise to inflammatory reactions in the glomeruli, invade the tubules giving rise to a medullary nephritis which extends to the pelvis. If drainage of the pelvis is maintained, the constitutional reaction and pathological changes in the kidney will be slight; but if obstruction to the urinary outflow takes place, localized or general suppuration may ensue. Retention through back pressure upon the secreting surface of the kidney, if allowed to remain, or not spontaneously relieved, gives rise to serious pathological changes in the kidney. This picture represents the so-called acute pyelitis. If retention in the kidney pelvis is already present and infection ensues, the condition is known as an infected hydronephrosis. If the obstruction is not relieved, a marked or complete destruction of the kidney takes place, pyonephrosis being the result. Thus, it will be seen that whether one is dealing with an acute pyelonephritis, infected hydronephrosis, or pyonephrosis, depends upon the extent and duration of the urinary obstruction.

Acute pyaemic kidney constitutes part of a general pyaemia. Focal suppurative lesions, often spoken of as septic infarcts, are unilateral; the kidney is enlarged, the areas may be multiple, and necrosis may take place; resolution, however, is the rule.

The symptoms of kidney infection vary according to the type of infection, and especially the secondary conditions present. They may be slight or fulminating reactions, or may be masked by a general toxaemia; or, in chronic infections, there may be no symptoms pointing to either kidney, the condition frequently being discovered through urinalysis.

Acute Pyelonephritis

The most frequent type of acute kidney involvement is acute pyelonephritis. The patient, following an infection of a tooth, sinus, the intestinal or genital tract, influenza, or furunculosis, as a result of some obstruction to urinary drainage, or, possibly without any of these predisposing conditions, is suddenly seized with a chill, fever, pain in the loin, local tenderness, the kidney may be palpable, and abdominal distention and constipation are usually present. There may be no pus in the urine and no bladder symptoms. If untreated, there is little remission for several days to two weeks, the temperature fluctuates, the pulse is seldom high, leucocytosis low, and sweats are common.

At this stage, rest in bed, a limited diet, thorough clearing out of the intestinal tract, and a complete flushing of the urinary tract with water are the indications. Water should be given by mouth, by rectum, and, if necessary, under the skin and in the veins. Alkalies may often be administered with benefit, through promoting diuresis and by changing the reaction of the urine, inhibiting the growth of the colon bacillus. Urinary antiseptics have comparatively little value at this stage. Urotropin, sometimes effective, may, on the other hand, cause kidney congestion or vesical irritation, and the analin dyes and balsams may be more efficacious during the acute stage.

If the local symptoms of pain and tenderness do not subside and the temperature drop, the indication is to establish drainage, and for this purpose nothing takes the place of the ureteral catheter. The response is almost instantaneous. Pressure upon the kidney is at once relieved; there is a cessation of septic absorption; and the catheter may be retained for days, during which time the kidney pelvis may be irrigated at frequent intervals.

With a subsidence of the local symptoms,

and a drop in temperature—which usually denotes the establishment of kidney drainage—pus, blood cells and bacteria appear in the urine, and frequency of urination and dysuria become pronounced symptoms. In the absence of urinary obstructions, acute infections have a tendency to subside spontaneously, or under medical treatment. If associated with obstructive lesions which are not relieved, they tend to progress toward complete kidney destruction after a long intermediate stage of chronic infection.

Chronic Pyelonephritis

In chronic pyclonephritis the infection is usually bilateral, the urine may show a bacteriuria or pyuria; there may be little febrile reaction; frequency and dysuria may be present, slight, or absent. Seldom is renal pain present except in cases of urinary obstruction or calculus. The symptoms and progress of the disease depend largely upon the interference with drainage, and, in this type of infection, not only is it essential to eliminate any possible extraurinary focus of infection, encourage climination from the intestinal tract, and build up the general body resistance, but, with the accurate methods of diagnosis available, a complete investigation of the urinary tract is most essential to determine the possible presence of obstruction to urinary drainage. By means of cystoscopic examination, ureteral catheterization, urinalysis, functional kidney tests, pyelography and intravenous urography, light may be thrown upon the subject which will lead to the adoption of measures which may save the kidney and clear up the infection. The majority of the instances of pyonephrosis represent neglected cases, often the result of prolonged medical treatment. Symptomless pyuria usually means upper urinary tract infection, and if the cause of the infection cannot be definitely localized in the lower urinary tract or genital tract, the kidneys should be investigated at

In chronic renal infection, repeated catheterizations and ureteral dilatations may prove beneficial: the removal of calculi which may be causing obstruction, the relief of pressure upon the ureter, and of obstruction of the lower urinary tract, are essential in promoting a cure. The removal of abscessed teeth, infected tonsils, the drainage of sinuses, increased elimination from the intestinal tract, the cure of localized suppurations, as a boil, or carbuncle, may result in the clearing up of the kidney infection. Flushing with water is essential, and urinary antiseptics and changes in the reaction of the urine are often more beneficial than in acute infections.

Vaccines are of doubtful value; intravenous medication is well worth trying in obstinate cases, and for this purpose Uritone, Arsphenamine and Mercurochrome have been employed.

Infectious in Children

The same types of acute and chronic infections of the kidneys are encountered in

children, in the following groups:

(1) in previously healthy infants, particularly girls, the colon bacillus being the most common infecting organism, there is the same train of symptoms; the intestinal reactions, however, are often more severe than in adults. (2) In poorly nourished infants, associated with other infections, the symptoms often being masked by the original condition, and (3) Recurring and persistent infections secondary to urinary obstruction usually due to the presence of congenital anomalies of kidney, ureter, bladder, or urethra.

The treatment of acute and chronic infections of the kidney in infants and children is the same as in adults; the tendency is, however, because of the more indefinite picture, and a hesitancy to submit them to instrumentation, to prolong medical treatment, when a complete urological investigation could be carried out with just as much safety and with as satisfactory a result, as in adults, and might demonstrate an underlying lesion which would prohibit a cure by such means.

Infections During Pregnancy

Renal infections during pregnancy are comparatively frequent. Retention of urine in the renal pelvis due to pressure upon the ureters—by the enlarged uterus—usually more marked on the right side—is present in most cases of pregnancy, and is more pronounced from the fifth to the seventh month.

Acute infection, presenting all the characteristics of acute pyelonephritis, may appear suddenly, should be treated as other cases of acute renal infection, and no hesitancy should be felt in establishing ureter catheter drainage if relief is not obtained promptly through or-

dinary medical measures.

Septic Infarcts

Cases of focal suppurative nephritis and septic infarcts are acutely ill and toxic, the symptoms are severe, and enlargement and tenderness of the kidney will be noted, with few urinary symptoms. Although nephrectomy was originally advised for this condition, it will usually subside under palliative measures.

While carhuncle of the kidney is a severe type of infection, it is not as acute and ful-

It occurs minating as the septic infarcts. subsequent to opening a boil or carbuncle in some part of the body, is a coccal infection, and may involve a considerable amount of Urinary symptoms may be kidney tissue. slight, and it must be differentiated from acute embolic kidney and renal abscesses. The treatment is surgical.

Perinephritic Abscess

Perinephritic abscess may be acute or chronic, and occurs spontaneously or in association with an acute or chronic kidney infection. A sudden rise of temperature, with progressive pain in the side, a gradual enlargement and tenderness with even swelling and redness in the loin, and a leucocytosis, together with x-ray findings which show a loss of the psoas outline and a curvature of the spine with the convexity away from the affected side, make the diagnosis clear. Often, however, the symptoms and physical findings are largely absent or obscured, and its presence is not discovered until the process has become extensive and may have caused severe damage to the kidney.

In cortical infections of the kidney, urinalyses may be negative, but the kidney is often enlarged and tender; temperature and chills are commonly present, and diminished renal function will be noted.

Pyonephrosis is primarily a surgical disease; its presence should be recognized and it should be treated as such.

The Rôle of the General Practitioner.—Much can be done by the general practitioner, in the prevention of renal infections, by recognizing their frequent occurrence, the many elements entering into their etiology, and, through regular health examinations, to detect, and, in so far as possible, eliminate such factors. This should lead to the removal of all foci of infection, regulation of intestinal function, increased elimination, brought about by changes in diet; increased fluid intake, regulation of the habits of individuals; and by the examination of sterile specimens of urine (catheterized in the female), for pus, blood, and bacteria, it should be possible to detect infections in their incipiency, and, if they are not readily eliminated by medical measures, to have the picture clarified by a complete urological examination.

Renal Tuberculosis.—In no class of urological cases can the general practitioner be of greater service than in the management of cases of Exhaustive studies have been tuberculosis. carried out during the past ten years which have somewhat modified our views of renal tuberculosis, These studies by pathologists and urologists connected with sanitariums where large numbers of cases of general tuberculosis are under observation for periods of years have shown that the only finding in very early cases of renal tuberculosis may be the discovery of tubercle bacilli in the urine; that the presence of tubercle bacilli in the urine denotes renal involvement; and that probably 70 per cent of the cases of renal tuberculosis are at first bilateral; also that very early non-destructive kidney lesions sometimes heal. The examination, by Medlar, of 100,000 serial sections of the kidneys in thirty patients who had died of advanced pulmonary tuberculosis, but who had not had clinical symptoms of renal involvement, showed, in 22 cases, that renal tuberculosis was present, and in every case in which both kidneys were examined, the disease was bilateral. He also found, in running through serial sections, evidence of occasional healing of minute initial lesions.

At the time when active symptoms of renal tuberculosis are manifest and such patients come under the observation of the urologist, destructive lesions are present, and, if the disease is unilateral, nephrectomy is indicated. Is it not possible that if those who care for cases of pulmonary, as well as other types of general tuberculosis, regularly searched the urine for the presence of tubercle bacilli, and made guinea pig inoculations, that occasional very early cases of renal tuberculosis would be detected which might be cured by general hygienic measures and heliotherapy? recognizing the fact that persistent pyuria and dysuria often denote renal tuberculosis, and that if in all such cases its possibility should be considered, fewer cases would pass the stage when the disease is surgically curable; and, furthermore, with the building up of resistance (a body force which has often been clearly demonstrated in the study of tuberculosis) the end results, when surgery is emploved, would be more satisfactory.

Renal Calculi.—When one considers about 50 per cent of all kidney operations are associated with lithiasis, the importance of this disease becomes apparent. The great amount of experimental work that has been carried out during the past few years. in an effort to ascertain the cause of stone formation. has brought out certain facts which are strongly suggestive and once again link the kidnevs with other body pathology and disturbances of function.

The relation of diet to stone formation, and especially the deficiency of Vitamin A, has been claimed by some to be a vital factor; the action of protecting colloids in holding the solution of crystals, and the influence of infection upon stone formation, have been shown to be more than coincidental. The injection of bacterial cultures—taken from the urine of persons with renal stones—into the pulp and root cavities of the teeth of dogs, have caused root abscesses and led to the formation of eal-culi. In certain instances, bacteria have been found to constitute the nucleus of a calculus, and, in others, calculi have been found to consist of an accumulation of bacteria. Gastrontestinal dysfunction seems also to have an intimate connection with stone formation.

As renal calculi are multiple in 40 per cent of cases and bilateral in 10 per cent, the seriousness of the condition is evident. Not every renal calculus should be removed; although some are spoken of as silent stones—which may be true as far as symptoms are concerned—they are not actually, or even potentially, inactive in so far as their ultimate effect on the

kidney is concerned.

Here, again, by periodical health examinations, the physician may, through regulations of diet and intestinal function, and the elimination of focal infections (especially when crystals are found in the urine), do much toward the prevention of calculus formation. The presence of a calculus should be suspected not only when patients complain of lumbar pain or colic, but when pus and blood cells are found in the urine; in every such case an x-ray should be taken, that a calculus may be discovered as early as possible and eliminated with a minimum of kiduey damage.

Once again, the physician is in a position of grave responsibility when he discovers the presence of blood cells in the urine, or, when the patient tells him of having hematuria which may have disappeared and his urine is then normal. That every case of hematuria should have a complete urological examination has been proved many times; and the discovery of a renal tumor that has given rise to no other symptoms than hematuria has often been noted. When a renal tumor has reached

sufficient size to be palpable, operation may prove of little avail, and, while deep radiotherapy may have a palliative effect, the hope for the patient lies in the performance of an early operation.

Polycystic Kidney.—Polycystic kidney disease is a condition which can well be handled by the physician, for, being a bilateral lesion, surgery is seldom indicated, and then only to relieve some complication such as severe hemorrhage or infection, in which instances, drainage of the cysts may rarely be indicated. These kidneys may reach large size, and when they do their irregular outline is often characteristic. Such patients, under a medical regime such as that instituted for interstitial nephritis, often live many years in comparative comfort.

The presence of an abdominal tumor should lead one to suspect a renal anomaly; mid-line tumors suggest a horse-shoe kidney; and the presence of a single kidney is always a possibility. Such anomalies, because of their interference with drainage, render the kidneys more susceptible to infection and other pathology, and, with the means of diagnosis available, such a possibility should always be

eliminated.

With the time allotted, it has been possible to only touch upon some of the more important phases of kidney pathology and their nonsurgical management—in the execution of which the physician plays a rôle that is in some ways the most important. He is the one who should most often discover the pre-pathological stage; who can institute measures of preventive urology, and also detect the carliest signs and symptoms of renal pathology, which may lead to its elimination by medical means; or see that the patient has the advantage of a complete urological examination at a time when the kidney may not only be saved, but its function restored.

DIETARY CONTROL OF CHRONIC HYPOTHROMBINEMIA IN CHILDHOOD

By I. NEWTON KUGELMASS, M.D., NEW YORK, N. Y.

From the Department of Pediatries, Fifth Avenue Hospital

A BLEEDING tendency is not infrequently observed as a persistent manifestation of apparently well children. They are undernourished for their body build, and are not derived from hemophilic families. Usually the bleeding symptoms are trivial and only presented as a complaint incidental to an irrelevant acute illness. Epistaxis and easy bruising are outstanding symptoms although other bleeding disturbances may occur. Physical examination is usually negative, and the clot-

ting time is prolonged or even normal; but determination of the clotting constituents reveals a decreased prothrombin or fibrinogen content of the blood. The anti-thrombin concentration is usually increased, but the platelets are normal in both quality and quantity. We have observed no evidence that the vascular endothelium is at all affected as judged from the tourniquet test and microscopic examination of the capillary nail beds.

Such benign bleeding manifestations are

evidences of nutritional deficiency. The outstanding factor common to all is a hypothrombopenia. Both prothrombin and fibrogen are derived from the liver. Their decrease in these cases is not a result of impaired liver function, but rather the consequence of protein deficiency. Prothrombin is a protein substance which, according to our observations, increases in the blood following high protein

diets, especially those containing viscera and gelatine. With the increase in prothrombin there is a diminution of the bleeding symptoms. The associated anemia in these undernourished children is unrelated to the bleeding, but is a result of nutritional deficiency.

The prevalent supposition that hemorrhage follows anemia is unfounded. We do not observe bleeding in acute or chronic anemia

even when the hemoglobin is as low as ten per cent and the red cells drop to one million. Never does hemorrhage occur in severe chlorosis or in any of the anemias unless there be bone marrow injury. Such is not the case in these children with mild recurrent bleeding following trauma. Furthermore there is no evidence of hemorrhage in the severest hydremias. Then the blood proteins are reduced to one third their normal level, which produces no disturbance of the nutrition of the vascular

endothelium. The basis for the hemorrhagic tendency in the group of children here presented is a diminished prothrombin or fibrinogen content of the blood, corrected within two weeks by the administration of a high protein diet. We have observed a hypothrombinemia in a group of boys who were referred to us as possible hemophiles. Thus has the "clotting diet" become effective in the control of a chronic hemorrhagic condition confused with hereditary hemophilia.

THE EXTERNAL EXAMINATION OF THE EYE IN THE DIAGNOSIS OF GENERAL DISEASES

III. THE IRIS, PUPIL AND LENS

By CONRAD BERENS, M.D., and JOSHUA ZUCKERMAN, M.D., NEW YORK N.Y.

The third of a series of three papers read before the Dallas Southern Clinical Society, Dallas, Texas, April 1, 1931,

H. Iris

 - 2. Ciliospinal reflex

H. The Iris

(1) Iritis—It is important to be able to diagnose iritis in the acute forms and in the insidions subacute and chronic forms. Whenever signs of iritis are detected the physician must conclude that it is caused by a general systemic disease, except when iritis follows traumatism or a perforating injury of the eye. Acute iritis can usually be diagnosed by the contracted pupil, the marked circuncorneal congestion that persists even after the instillation of epinephrine, and especially by the detection of blood vessels in the iris. In subacute and chronic cases, posterior adhesions may form between the iris and the anterior capsule of the lens, with practically no evidence of inflammation. It is important that the

general practitioner detect iritis not only in order to determine the etiology, but also in order to save the eye, and to make the differential diagnosis from glaucoma. Glaucoma is a condition of the eye characterized chiefly by increased tension of the eyeball, i.e., increased intra-ocular pressure. The treatment usually prescribed for iritis might permanently damage a glaucomatous eye.

Increased tension may also accompany acute and chronic iritis. If the ciliary body, as well as the iris, is inflamed, an exudate may appear in the anterior chamber, and deposits may be found on the posterior surface of the cornea. If this condition is not recognized early the function of the eye may be seriously damaged by the forma-

TABLE I DIFFERENTIAL DIAGNOSIS

	Acute Conjunctivitis	Acute Glaucoma	Acute Iritis	
Age	Any	Usually over 35	Rarely under 20	
Pain	None	Severe, continuous	Especially at night	
Vision	Good or slightly blurred	Much reduced	Somewhat reduced	
Secretion	Mucopurulent	None or watery	None or watery	
Conjunctiva	Conjunctival congestion, especially of eyelids	General congestion, especial- ly scleral	General congestion, especially circumcorncal	
Cornea	Clear	Cloudy, sometimes rough	Cloudy	
Depth of Anterior Chamber	Unchanged	Shallow	Unclianged	
Iris	Unchanged	Discolored	Vessels congested, posterior synechia	
Pupil	Unchanged	Dilated, sometimes oval	Contracted, synechia (adhesions between pupil and the lens capsule.	
Tension	Normal	Markedly increased	Normal or occasionally raised	
Fields of Vision	Normal	Concentric contraction, en- largement of blind spot	Generally normal but central scotomata are not rare	
Treatment	Astringents, antiseptics	Eserine, pilocarpine, iridec- tomy (atropine contraindi- cated)	Atropine	

Summary

Acute conjunctivitis is characterized chiefly by mucopurulent discharge.

Acute glaucoma is characterized chiefly by hardness of the eyeball (increased tension).

Acute iritis is characterized chiefly by contracted pupil and circumcorneal congestion.

tion of adhesions (posterior synechiae) between the iris and the anterior capsule of the lens.

- (a) Causes of iritis—The commonest causes of iritis are syphilis, tuberculosis, diabetes, gonor-rhea, and so-called "rheumatism." We prefer to classify the rheumatic group under focal infections
- (b) Differential diagnosis—It is almost impossible in most cases to determine the cause of the iritis from the appearance of the iris. Gonorrhea, diabetes and focal infections usually produce a superficial inflammation, whereas tuberculosis and syphilis usually produce a deeper inflammation and are frequently characterized by the presence of papules in the iris.

Appropriate antisyphilitic treatment usually effects a rapid disappearance of these lesions in syphilitic iritis, whereas in tuberculous iritis the papules and the inflammation of the iris exist for a long time, and the papules recur at intervals. In determining the etiology of iritis, careful bacteriologic studies, determination of the blood chemistry, roentgenograms and the most careful physical examinations are indicated. When one finds a mildly positive reaction to the intracutaneous tuberculin test, and several complicating focal infections, our impression is that the complement fixation and agglutination tests and

other serobacteriologic examinations with bacteria recovered from various foci sometimes give valuable information concerning the area of focal infection to be attacked first.⁶

(2) The effect of mydriatics and miotics on the pupil in health and disease—Cocaine dilates the pupil by direct stimulation of the sympathetic fibers. When the sympathetic is paralyzed, even a 5 per cent solution of cocaine will fail to dilate the pupil. Epinephrine dilates the pupil by direct action on the dilator muscle.2 De Schweinitz has shown that epinephrine becomes very active when the sympathetic is cut, or when the superior cervical ganglion is removed. Rischard concluded from his experimental study of the innervation of the iris that the oculomotor nerve has no direct action on the iris. When sympathetic innervation is experimentally eliminated, the iris The oculofails to respond to any stimulus. motor nerve can therefore act on the muscles of the iris only through the sympathetic nerve. He believes that the iris contains a single muscle innervated directly by the sympathetic nerve and that the oculomotor nerve acts indirectly by inhibiting the action of the sympathetic. action is analogous to the nervous mechanism of the urinary bladder. Atropine, duboisine, and hyoscine dilate the pupil and paralyze accommodation through direct action on the ending of the ciliary nerve which supplies the ciliary muscle (the muscle of accommodation). The action of these mydriatics is unchanged in sympathetic paralysis. The miotics are esertine and pilocarpine. They produce marked pupillary contraction and spasm of accommodation. The action of these miotics seldom lasts longer than a day but the action of atropine lasts for six or eight days or even longer.

- (3) Normal iris reflexes-The pupil is made smaller by contraction of the circular band of muscle called the sphincter pupillae. It is one millimeter in diameter and lies at the pupillary border of the iris. This muscle is innervated by the third nerve. The pupil is dilated by the dilatator pupillae which is innervated by the sympathetic. For the careful study of pupillary reflexes, without complicated apparatus, moderate illumination should be obtained if differences in the size of the pupils are to be detected. Paralysis of one cervical sympathetic may remain unnoticed in illumination of high intensity, for under this bright light both pupils may be small and approximately equal. To test the direct light reflex as well as the ciliospinal reflex, the patient should look into the distance and his attention should be diverted if possible.
- (a) Pupillary contraction—The direct light reflex should be tested by directing light into each eye separately and noting the pupillary re-action. The bulb and condensing cap of the May ophthalmoscope are ideal for this purpose. The consensual reaction is observed by throwing the light into the right eye and observing the pupillary reaction of the left eye and vice versa. action is brought about through the decussation of the fibers of the optic nerve in the chiasm and also through association fibers between the nuclei of the two sides of the brain. To test the convergence-occommodotion reaction the patient is asked to look from a distant to a near object (a dot on a card or the white head of a small pin at 10 inches). Differences in equality, regularity and reaction should be noted. The pupils should contract when the eyes converge on a This is caused rather by connear object. vergence than by accommodation because this reflex takes place even in highly myopic patients who have little or no accommodation. The contraction of the pupil under attempted forced closure of the eyelid, the eyelid closing reflex of von Graefe, is especially noticeable in facial paralysis.
- (b) Pupillory dilototion—Psychic stimuli cause dilatation of the pupil, and fear or anger may produce maximum dilatation. To test the ciliospinal reflex, the skin of the neck is pinched or stuck with a needle, or a loud noise may be made, to note whether dilatation of the pupil takes place under these influences. From these

statements it is evident that the width of the pupil is constantly changing as the result of psychie influences and under the influence of light, convergence, and stimulation of the cervical sympathetic. The diameter of the pupil in moderate illumination varies from 2.5 millimeters to 4 millimeters but is influenced by many factors. In babies and in old people the pupil is small; in myopic patients and older children the pupil is usually wider. In sleep the pupil is small due to the absence of sensory and psychic dilating stimuli. Auditory and sensory stimuli produce dilatation of the pupil even in sleep. In the excitation stage of the administration of a general anesthetic the pupil is dilated but reacts to light, the pupil becomes wider as sleep is produced, and in deep narcosis there is no reaction to light. If collapse occurs under anesthesia the pupil dilates and does not react to light. The pupil is also large at the time of death but after death it contracts, and atropine and eserine are ineffective.

(4) Pathologie reflexes—Normally, both pupils should be of the same size; inequalities usually

denote a pathologic change.

(a) Pupillary inequalities—Marked differences in refraction of the two eyes (anisometropia), congenital anomalies, rupture of the sphincter of the iris, anterior and posterior synechiae, mydrities. In unilateral blindness the pupil is usually large on the side of the lesion. The direct light reaction, the consensual light reaction from the seeing to the blind eye, and the convergence and accommodation reactions may be present. In bilateral blindness both pupils are wide but the convergence reaction is usually retained—the pupil may contract if the patient attempts to look at his own fingers. In rare instances even in complete blindness the direct light reflex may be retained.

(b) The cause of poralysis of the sphincter pupillae muscle may be in the muscle, the ciliary ganglion, the oculomotor nerve or the oculomotor nuclei. The most common cause of involvement of the oculomotor nuclei is congenital or acquired syphilis. Although these parts are seldom affected in tabes, in progressive paralysis involvement is noted in approximately 12 per cent of the cases. Diphtheria, influenzo, lead and olcohol poisoning are other causes. If the lesion is extensive accommodation is usually also affected.

(c) Weakened oction (paresis) of the iris—Corticol injuries, increased introcranial pressure, senile dementia and hysterio may weaken the action of the sphincter of the iris. Alropine, homatropine, hyoscine, duboisine, traumatic rupture of the sphincter and glaucoma are other causes of weakened action of the sphincter.

An iris which does not respond to light but reacts actively to accommodation and convergence is called (d) an Argyll Robertson pupil. The

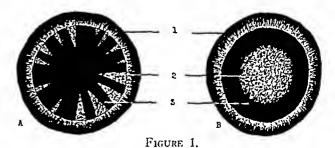

development of this condition is slow and may be unilateral; when fully developed the direct and indirect light reflex and the psychic and sensory ciliospinal pupillary dilatation are usually destroyed, but the reactions to convergence and to closure of the eyelids are unaffected. This lesion occurs in approximately two-thirds of the cases of tabes and about half the cases of general paralysis. It may also be caused by chronic alcoholism, nicotine poisoning, and injuries. Argyll Robertson pupil has also been seen in senile dementia, encephalitis lethargica, disseminated sclerosis, tumors of the midbrain, diabetes, syringomyelia, and recently Foster Moore has collected several examples of a nonluctic type which is congenital.

Adhesions between the iris and the posterior surface of the cornea or between the iris and the anterior capsule of the lens may cause irregular pupils.

(5) Affections of the sympathetic nerve supplying the dilatator pupillae muscle.

- (a) Paralysis of the sympathetic nerve—The pupil is small due to the unopposed action of the sphincter pupillae but mydriatics of the atropine, hyoscine, and duboisine group produce dilatation. Eserine and pilocarpine produce contraction. Cocaine is inactive because it acts directly upon the sympathetic endings. As previously stated, epinephrine has a marked dilating effect because it acts directly on the dilator muscle. symptoms are narrowing of the palpebral fissure due to slight ptosis from paresis of the superior palpebral muscle of Müller, dilatation of the vessels of the face and neck, with increased perspiration. This may also be revealed by observing the excessive perspiration on the hat band of the patient suffering with this lesion. enophthalmos may also be present due to relaxation of the orbital muscle of Müller.
- (b) Stimulation of the sympathetic produces exophthalmos with constriction of the vessels of the face, widening of the palpebral fissure and mydriasis. Lesions of the sympathetic pathways

to the iris are commonly caused by cranial injuries and spinal cord injuries. Pressure from aneurysms, glands, growths in the thorax and neck and simple goiter frequently have been reported as causes, but in a large percentage of cases no discoverable cause can be found. To summarize: paralysis of the sympathetic produces miosis, narrowed palpebral fissure and enophthalmos; stimulation of the sympathetic produces mydriasis, widened palpebral fissure and exophthalmos.

Two common types of cataract as they appear by focal illumination: A. cortical cataract; B, nuclear cataract; 1, iris; 2, cataract; 3, pupil.

I. LENS

(1) Cataract—Under normal conditions the lens is transparent and therefore not visible on inspection. When it loses its transparency, i.e., when it becomes cataractous, it may be seen as a grayish-white mass occupying the pupillary area in either of the two forms as shown in Fig. 1. The most common causes of cataract are as follows: (a) senility, the most frequent cause in patients over fifty years; (b) general diseases (diabetes, tetanus, epilepsy, poisoning by naphthalin, ergotism, pellagra); (c) faulty development (producing congenital cataract); (d) trauma. When the capsule of the lens is torn the aqueous is absorbed by the lens and cataract results. Excessive heat, sunlight or electric light may also cause cataract; (e) eye diseases. Infected corneal ulcers, retinitis and choroiditis may give rise to complicated cataracts.

SURGICAL RELIEF OF INTRACTABLE PAIN

By FRANCIS C GRANT, M D, PHILADELPHIA, PA

From the Neuros are, cal Chaics of the Hospital of the University of Pennsylvania and the Graduate Hospital Philadelphia Pa Read before the Section on Neurology at the annual Meeting of the Medical Society of the State of New York April 5 1933

INCE the dawn of medicine a great part of the physician's work has been concerned with the relief of prin disease produces pain the plea of the sufferer is for its relief. Cure the disease if possible but first stop the pain Frequently, the condi tion is incurable and the patient doomed but if his pain can be relieved, his manner of dying will be less distressing For centuries opium was the only known analgesic Then Magendie identified the sensory functions of the posterior roots of the spinal cord and Mayo showed that the trigeminal nerve carried pain sensa tions from the face Little by little surgical measures for relief of pain were introduced beginning with peripheral section of cutaneous nerves followed by cutting of the posterior spinal roots supplying the punful segments until finally Spiller1 demonstrated the position of the pain fibres within the antero lateral columns of the spinal cord By section of these afferent pathways for prin within the spinal cord at the fourth thoracic segment complete analgesia for pain may be produced on one or both sides of the body below the ensiform cartilage Recently Toerster' and Peets have shown that cord section (cordotomy) of the antero lateral tracts may be performed with safety on one side at least as high as the second cervical segment thus carrying the level of anesthesia for pain as high as the elavicle Thus pain from carcinoma of the breast due to involvement of the brachial pleaus may be relieved

On the Neurosurgical Service at the University Hospital due to the interest of Dr Charles H Frazier in trigeminal neuralgia, methods for the relief of pain in the face were first considered The means of checking the agony of tic douloureux are too well known to require further comment. But the pain from cancerous lesions about the mouth and face especially when the disease involves the upper or lower lip, nose, maxillary antrum or dorsum or side of the tongue may be completely relieved by injection of alcohol into the second or third division of the trigeminal or by sec tion of its sensory root behind the ganglion And not only is the pain from the cancerous lesion itself relieved, but also radical methods for its removal are painless The patients willingly accept fulguration, excision, im plantation of radium or other treatment up to the limit of tolerance because of their free dom from pain So often patients with malignant disease in this region are encountered who are suffering severe and constant pain

and who dread further or more intensive treat ment because it aggravates their suffering. It seems certain that some of the cases in this series who are alive at the end of five years survived because their freedom from pain permitted them to sleep, to ext comfortably and to receive the maximum amount of treatment without an increase in their distress

It should be stated that the pain from malignant disease involving the floor of the mouth or tonsil with pain referred to the throit or deep in the err is not benefited by injections of the trigeminal Occasionally a sub-occipital cranicetomy with section of the fifth and ninth nerves and the upper three cer vical postenor roots has been attempted but the relief afforded has never been nearly as satisfactory as in those instances where the lesion lies completely within the sensory distribution of the fifth nerve (See Table I)

Not infrequently carcinoma of the face or mouth metastasizes to the glands of the neck, forming large, solid nodules and causing much pain in this area. Under these conditions a laminectomy and rhizotomy of the appropriate cervical nerves, usually from the first to the fifth cervical posterior roots, can be performed to relieve the pain. By this procedure a band of anesthesia is produced extending from the vertex of the scalp to the clavicle.

When a mammary cancer spreads into the axilla or supra-clavicular triangle, producing pain in the arm and hand, the only method of relief hitherto available has been rhizotomy from the fifth cervical to the first thoracic posterior roots on the affected side. procedure, although it relieved the pain, has two serious defects. An extensive laminectomy of six or seven laminae is necessary and section of six posterior roots is a procedure accompanied by post-operative shock. thermore, when the posterior roots are sectioned, all types of sensation are abolished including position and muscle sense. Consequently, although the patient can move the arm freely, it is not a useful member, for loss of sense of position interferes greatly with proper function. High cordotomy of the antero-lateral tracts abolishes pain sensation but leaves touch and position unimpaired. Moreover cordotomy may be performed through a smaller incision with the removal of but three laminae and is, therefore, a much less formidable surgical procedure. We have had no experience with bilateral cervical Unilateral cordotomy in this cordotomy. region, properly performed, does not seem to interfere with the respiratory mechanism, as in our two cases the diaphragm and the intercostal muscles continued to function normally.

Due to the original brilliant clinical observations of Spiller, proving that the afferent tracts for pain passed through the anterolateral columns of the spinal cord and to the development by Frazier of the surgical technique for severing these tracts in the cord, cordotomy for relief of pain has been freely used in the Neurosurgical Clinic of the University Hospital. Seventy-four cordotomies have been performed upon seventy-one patients.

Cordotomy has three distinct advantages over other methods of relieving pain. First, since in the antero-lateral columns of the cord, the pain fibres are compactly collected, a section there produces the largest possible area of anesthesia. Secondly, pain and temperature sensations alone are obliterated without involvement of touch or position sense, and hence the usefulness of the lower limbs is not impaired. Lastly, the operation requires only

a small laminectomy and is, therefore, a much less exhausting surgical procedure. But cordotomy has the disadvantage that unless the incision into the cord is accurately placed, the pain may not be completely relieved or the motor pathways may be damaged, resulting in paralysis of the legs and interference with sphincter control.

The technique of cordotomy presents but one difficulty. If the section of the cord is not accurately made the pyramidal tracts may be injured or insufficient pain fibers sectioned to give complete relief. By the use of gas oxygen, plus novocaine, it is possible to cut the pain tracts under local anesthesia and to determine with accuracy the level of loss of pain sensation by sensory tests carried out in the operating room. Muscle power in the leg on the side of the section can be tested at the same time. This is a distinct advance in technique that has practically eliminated any damage to motor pathways. Reference to Tables III to VI gives in detail the results with this procedure. In the last 26 cases, there has been no evidence of motor weakness in the lower limbs and no sphincter involvement lasting over three days. In all these cases the relief of pain has been complete.

The point of election for performing cordotomy is the third thoracic spinal segment, lying beneath the tip of the second and the body of the third thoracic vertebrae. At this level, the cord is readily accessible. A lamirectomy of the second, third and fourth thoracic spines affords sufficient exposure for a unilateral section, although if both tracts are to be cut, the fifth thoracic spine may be included as a larger exposure is needed.

Recently two cases were encountered with pain in the arm due to metastasis from carcinoma of the breast. Both were active women who but for the pain would have had useful limbs. Rhizotomy would bring relief but interfere markedly with the use of the arm, for all sensation would be lost. In the first case, cordotomy was performed at the third cervical segment and the third, fourth, fifth and sixth cervical posterior roots were sectioned. pain was satisfactorily relieved and position sense being unimpaired, the arm and hand functioned normally. In the second case, cordotomy was performed at the same level but no posterior roots were cut. The result was equally gratifying. Unilateral cordotomy at the level of the third cervical segment seems to be a safe and, judging from the results, a justifiable procedure to relieve pain in the

In deciding upon the necessity for a unilateral or bilateral cordotomy, a careful description of the distribution of the pain is

tracts, although the pain seems largely uni-If the malignant lesion is rapidly growing, and if the pain while still unilateral involves midline structures both anterolateral tracts should be cut to assure permanent relief. While bilateral cordotomy takes longer to perform than section of but one tract and has twice the chance of complications, nevertheless, in pelvic cancer it is often to be preferred as more certain in its results. In experienced hands, using the technique described, a bilateral cordotomy is but slightly more dangerous than a unilateral section.

Is relief of pain by operation a proper procedure? If the pain is produced by a chronic condition which of itself will not shorten life and if the pain is of sufficient severity to incapacitate the patient and requires morphine for its relief, the answer is unquestionably in the affirmative. No one today hesitates to advise operative relief for the pain of trigeminal neuralgia. Osteo-arthritic conditions, old tubercular lesions of the hip, tabetic crises, a painful amputation stump, injuries to the pelvis with scar tissue formation about the sciatic nerves cause suffering easily comparable to tic douloureux and cordotomy affords prompt and permanent relief.

But when the pain is caused by cancer and the patient's expectation of life is definitely limited then the question of expediency arises. Is it proper to subject a patient with cancer who may live for six months or a year to the discomforts of a surgical procedure for relief of pain when he can be kept fairly comfortable with morphine for the short time he will survive. While it is well recognized that there are arguments against further operative procedures in patients in a hopeless condition from malignant disease, nevertheless, to die painfully and slowly from cancer is a dreadfully distressing end. In spite of increasing doses, morphine gives only intermittent relief at best. Between hypodermics the pain may be intolerable. And the pain from cancer rarely lets up; is present night and day and rapidly exhausts the patient. It is this bad situation which operation can relieve. Even if death follows surgery, and although most of

these cases have had advanced cancer, the operative mortality has only been about 13% in the cordotomy and 6% in the sensory root avulsion group, it is a quick and merciful death. Operative recovery is followed by relief of pain. The patients can eat, sleep and unless bed-ridden as a result of their cancer, can go about their business undisturbed. It only requires one or two striking examples of the beneficial effects of relief of pain to arrive

at a correct answer as to the expediency of its surgical removal. Pain can and should be relieved promptly by surgical measures and the sufferer should be thus informed before he is so exhausted by his distress that he has become a hopeless operative risk.

My sincere thanks are due to Dr. Charles H. Frazier for his permission to report these cases and for the use of his records in the pre-

paration of this article.

THE HEALTH EXAMINATION, LIFE SERVICE AND THE FAMILY DOCTOR By C. WARD CRAMPTON, M.D., NEW YORK, N. Y.

Delivered before the Medical Society of the County of New York April 24, 1933

ACIAL Progress. One of the most encouraging signs of the progress of the human race is the gradual increase in foresight it has shown in managing its own affairs. This sometimes may be observed in the lives of individuals. In the medical field, at the dawn of history, the doctors had for their patients only such as were already in mortal agony or in fear of immediate death. Centuries later we observe a tendency to seek the services of the physician at an earlier stage when pain and weakness reached the point of requiring the patient to seek his bed. Thus medical diagnosis and treatment were largely clinical, named after the old Greek word "cline," meaning bed or couch.

As time went on and foresight increased, physicians were called upon at a still earlier stage to serve those who were sick but yet able to get about. Today there dawns the period when foresight and intelligence are counseling men to apply for medical service before nature warns of the presence of disease. The human race is slowly advancing, it is calling on the doctor for counsel earlier and earlier in the course of disease. Sometimes men follow these counsels. All this is made possible by the fact that disease may be present and recognized before laggard nature has made it obvious by pain and disability, and the public are becoming aware of the fact.

That disease almost invariably shows preclinical signs is a fact that is slowly gaining recognition.

Warnings and Forerunners. Perhaps we may coin a new aphorism "Nothing in nature is sudden."

A stroke of lightning comes from slow gathering electrical tension, an earthquake is but a readjustment of increasing strains in the bowels of the earth, and an apoplexy is only the result of an accumulation of causes often tragically, but perhaps mercifully silent. But sudden?—no! Accidents and infections seem to be exceptions but are they not largely preventable?

In this thesis lies preventive medicine with its two large divisions preclinical diagnosis and its service of preclinical therapy which will be referred to later.

The destruction of men, of nations and races is never sudden.

The camel's back may break suddenly, it is true, and the last straw will get the blame instead of the long accumulated crushing load.

"Nature's discipline is not even a word and a blow, but a blow without the word."

—THOMAS H. HUXLEY

Constructive Medicine. The public has found out something else. They believe that they can get a higher degree of health, happiness, and efficiency than is indicated by the mere absence of disease. They want better lives. Some of them are looking to the medical profession for guidance, many are not. This is the field of positive or constructive medicine.

Health Examination the Essential, personal preclinical medicine and constructive medicine should be based upon exact scientific knowledge of all men in general and their environ-To this should be added exact, special knowledge of the particular man and his individual environment. This requires an examination of the man, his body, his mind, his environment and how he reacts to it. This is the health examination. It has many variations.

Kinds of the Health Examination One of the most interesting health examinations in history gives an example of what can be done by a high powered concentration of medical service operating under the conditions of mechanized efficiency

One hundred and fifty men, factory workers, were stripped and fined up. They passed in The physician made a quick, general observation of their carringe, gait and skin He listened to the heart, feeling the pulse at the same He looked at the tongue He called off his comment to a clerk and passed on to the next He gave one minute to each man This oneminute examination is a classic in the history of the health examinations, an example of extreme brevity and of high efficiency per unit of time and per dollar expended. It is a flash of medical technocracy. It is something upon which to ponder

School Eraminations There are other quick health examinations for example those done in the public schools The daily, morning hygienic inspection of one million pupils in New York City schools by twenty-five thousand teachers, is in principle a health examination. This is done every day for two hundred days in the year, and perhaps constitutes the most extensive health procedure that the world can display

Then there is the medical inspection of twentyfive million children by the medical school inspectors of the United States This takes longer and occurs less frequently I believe, however, that the twenty-five million examinations of school children should be made annually and that they should be made by qualified physicians in their own offices I believe also that they should not be paid for by the public, but by the parents who with the pupils, are the direct beneficiaries I believe that if the County Medical Societies throughout the country were seriously to undertake to bring these twenty five million pupils to the offices of the private physicians, where they belong, it would be done, much to the profit of the children to the advancement of the science and the practice of medicine

Boy Scouts and Camp Fire Girls There are various other forms of health examinations, in industry, in insurance practice in the field of the life extension institutes and in private practice The form to which I shall give my attention for the moment is that which has been adopted in principle and already begun to be put into practice by the Boy Scouts of America and the Camp Fire Girls These two organizations have a combined membership of over one and onehalf millions

In the future it is very likely that twenty five per cent of the population of America will have passed under the influence of membership in there two organizations for a year or more of their lives There are similar organizations that

are paying interested attention to this subject Combined they might reach almost the whole

population

When these two groups are under way, in New York City alone there might well be from five hundred to one thousand health examinations to be done annually by every qualified general practitioner These examinations will be done by some one, perhaps by physicians in the employ of insurance companies or life extension institutes, or under some economical and highly efficient mechanized plan of socialized medicine they will be done

General Utility Record The plan provides that each member will get a health examination As a result he gets the record and recommendation of the physician, in so far as it is expedient He keeps this record It is utilized not only in hus own organization, but, we hope, by the schools, the summer camp, the YMCA, the church or municipal playground, the athletic field or wheresoever physical condition is a requirement or a goal for attainment

Use to Physicians This record is of service when its possessor goes to another physician It is added to annually by successive clinical or preclinical examinations and it becomes a life record Upon it can be based a system of consistent life management service rendered by the physician It is designed to become the basis of the practice of the new-fashioned family physician and the basis of an important development in medical science

Life Record The medical feature of this life record includes among other things, the records of health examinations, and for this purpose the health examination includes the following factors

Factors in Health Evanination The health examination is, first of all, a regular medical examination for the discovery of pathological conditions, illness or disability present or threatenmg to come in the future. This is regular medical work and no honest and reasonably capable physician should liesitate to undertake it

It is thorough however, and has two phases It is the regional examination in which the body is gone over from head to toe. It is concurrently also an organic examination where all findings are reviewed and classified under orgamzed systems One must get a workable understanding of the circulatory system, the digestive system, the autonomic nervous system and the several endocrine glands. Thus, we might say, the examination is both geographical (by regions) and organic (by systems)

Examination Routine As a matter of convenience, however, the examination is done in a practical routine procedure For example, the patient strips and, with a sheet or not, steps on the scales and is weighed. Those parts of the examination which can best be done while the

patient is standing are then done. The heart is examined, the blood pressure is then taken in the standing position and the pulse recorded.

The patient then lies down, the heart sounds are again observed, the blood pressure and pulse rate are again taken. Such parts of the examination as can best be done while lying down are then done.

The patient then sits up, reflexes are tested, gall bladder palpated, etc. Then he turns on the face for an examination of the spine. Standing again, a rectal examination is done on male patients and urine passed in two glasses. A catheter specimen is taken from adult female patients, and a pelvic examination is done.

The patient then dresses and an examination is made of the eyes, ears, mouth, nose and throat. The teeth and the sinuses should always be examined by trans-illumination. He is dismissed to return again in a few days when the laboratory reports are completed. He receives his instructions and is given such records as are expedient for him to have for future use.

Health Service. As a rule, the health examination is the beginning of a health service. The examiner becomes the health adviser. He treats, corrects and advises in the several departments of medicine in which he feels competent to serve. If he feels the need of special diagnosis, special surgery, or special therapy, he is the one to select a specialist and he is the one to whom the specialist should return his report and his patient. He should, however, send his patient to the specialist with a full report and require a full report in return. The specialist should have the advantage of the fullest available knowledge of the status of his patient. The following out of this procedure may result in much good.

It would be a better world if the 125,000,000 persons in the United States were to live their lives guided by competent medical advisers. The real burden of the cost of medical care would be lifted from costly emergency, despairing attempts at repair of wreckage. It should be expended for "pre-trouble maintenance." It is by some such process, rather than a resort to a mechanized form of socialized medicine, that the way forward may profitably be sought.

Scope of Health Examination. The health examination at its best is not only a search for clinical and preclinical signs of illness. It seeks to utilize all other sources of information in the

hope of getting guidance in the management of illness, of health and life in general.

Historical Data. It is good practice to have the patient contribute as much as possible to his own examination by furnishing on convenient blanks pertinent information concerning his heredity, his previous illnesses and operations and the way he is handling his life with reference to sex, diet, exercise, work, sleep and recreation. His mental status is quite as important as his physical status. It is good practice to let him reveal his chief anxieties, his chief incentives, his attitude, his satisfactions and his outlook. With these facts in mind, the examiner has a far better chance of giving instructions that will be followed and become effective.

Anatomical Data. From the anatomical field something can be gained by observing the form structure, posture and constitution of the patient and recording height, weight and girth of the chest and abdomen.

Physiological Data. In the young, growth and physiological age, or the process of developmental ripening, must be watched, for their disorders may be quite serious. Posture has a significance all its own.

In the old, the hardening chest and the bulging, drooping abdomen may well be heeded as the anatomical signs of decreasing physiological vigor.

It is in the physiological field that we may reap valuable information very quickly and easily. If one takes the blood pressure both standing and lying down instead of only in the sitting posture, a useful index of circulatory efficiency is found.* If the patient is given 15 grains of ordinary carmine in three capsules with the evening meal, the speed and efficiency of clearance of the gastro-intestinal tract is indicated. The sedimentation test, blood test, Sergent test, the head lines and various other reflex data have their service.

The Health Examination, Life Service and the Family Doctor. The health examination is not an isolated event; it is a dynamic part of a continuing life record. The health examiner becomes the continuing life counselor. The establishment of such a relation of doctor to patient will mean much to medical practice, medical science and medical service. It may mean that the family doctor has come back.

^{*}This test has just been adopted by the National Collegiate Athletic Association of America as "a reliable estimate of cardiac reserve."

CONTRALATERAL CAVERNOUS SINUS THROMBOSIS

Following Chronic Purulent Otitis Media

By ADOLPH WEIZENHOFFER, M.D., SCHENECTADY, N. Y.

Read before the Schenectady County Medical Society, February 7, 1933.

N Feb. 1, 1932, I reported in this, the New York State Journal or Medicine, a case of contralateral cavernous sinus thrombosis following a furuncle of the external auditory canal resulting in recovery. The case now presented was also contralateral in position, but followed an acute exacerbation of a chronic purulent otitis media. This patient, unfortunately, did not recover.

On Aug. 24, 1932 Mrs. E. W. aged 68, cance to me with the following history. During scarlet fever in childhood she developed a running left ear which continued to discharge till her eighteently year. For some time previous to her present illness she had intermittent attacks of earache which seemed to yield to local applications of mustard plaster. The patient was certain, however, that she noticed no discharge during these attacks. For the past five days she had a severe left earache, for which she applied the usual remedy. She fell asleep on the plaster and on awakening found her ear and the side of her face badly swollen and inflamed.

on the side of her face badly swollen and inflamed.

On examination, besides the mustard burn, there was swelling and complete closure of the canal, giving the appearance of a furunculosis, except that the tenderness was less exquisite than one would expect. Two days later, the swelling having subsided, the canal was found completely filled with polyps. It was noticed now that the left corner of the mouth drooped slightly. The family insisted that this condition was always present. The patient, however, was able to close the left eye tightly and to raise the left corner of the mouth voluntarily.

Aug. 30. X-ray showed marked sclerosis of the mastoid, some posterior cell destruction and possible pus formation. Temp. 101, P. 88. Urlnalysis: Sp. Gr. 1006, no albumin, sugar or casts. The blood count was W.B.C. 15, 700, Polys 88%, Lymphos 10%. A blood culture taken at this time was reported 72 hours later as positive for Sambulogorer. Album.

tive for Staphylococcus Albus,
Aug. 31. The temp. varied from 98.6 to 101.4. There
were no chills or sweats. Spinal tap yielded a fluid
that was clear, colorless and under normal pressure.
There was a faint trace of sugar and the globulin was
not increased. The cell count was 6.

Sept. 2. Operation was decided on without waiting for the result of the blood culture. Just before operating it was first noticed that the right upper lid was red and swollen. The mastoid was of ivory hardness. On removing the surface of the bone in the region of the supramental triangle, pus was found oozing from the sieve-like perforations in the bone. A culture of this

pus showed diplitheroid bacilli. The lateral sinus was covered by dense bone and there was no exposure. On removing the posterior canal wall, large quantities of green foul smelling pus welled up under pressure, much more than could have been held by the niddle car cavity alone. The middle car was cleaned out rapidly, the posterior canal wall was lowered, the bridge removed and flaps made. The upper half of the incision was closed with metal clips and drains placed in the lower half and in the canal.

Sept. 3. The facial palsy scemed more marked, the left eyelid not closing completely. The right was more swollen and red, there was proptosis of the cychall, chemosis of the conjunctiva and ocular movements were somewhat restricted. The temp. varied from 103 to 104. Blood count: R.B.C. 3, 400,000, Hb. 55%. W.B.C. 19,600, Polys 88%, Lymphos 9%. A transfusion of 300 cc. of citrated blood was given.

Sept. 4. The temp, varied from 102.4 to 104, pulse 100. Patient was drowsy and restless. The car was draining profusely, the discharge being foul smelling and brownish from admixture of blood. The right eyelid was more swollen and red and could not be opened and the exophthalmos was more marked. The left upper lid was now slightly swollen and red, motion of the eyeball was normal but the pupil was dilated and reacted sluggishly to light.

Sept. 6. Patient was much weaker. Transfusion of 300 cc. of citrated blood will glucose was given. Blood taken three days previously for culture was sterile. The left eye was wide open and the swelling of the lid was gone, while the condition of the right eye was unchanged. The temp, rose to 102, the pulse to 140 and the patient died that night.

The presence of polyps and of fetid purulent discharge point to a strong probability that a chronic purulent otitis had been active though mild for a long time. The infection entered the blood stream through the floor of the tympanum into the jugular bulb. The profuse purulent discharge during and after operation point to an extension of the process intracranially. It is impossible to say whether it remained outside the dura or had penetrated the brain substance, for it is possible for the infection to pass into the brain without involving the subarachnoid space. There surely was no general meningitis as was shown by the spinal tap and the absence of any meningeal symptoms.

THE EXECUTIVE SECRETARY

When several groups of members in casual conversation at a medical society fall naturally into the discussion of a topic, that subject is one in which physicians generally are deeply concerned. A common topic of informal conversation at the meeting of the First District Branch on October 11, was the recent appointment of an executive secretary by the Westchester County Medical Society, the host of the Branch,

Doctors have always been ready to say that the medical society should take some action on whatever condition is under discussion; but the difficulty has been to find anyone to devote time and energy to doing that duty. The extensive provisions for giving free treatment to the indigent sick have made every doctor aware of his own personal interest in the problem of the effective distribution of medical service; so that what formerly concerned him in only an academic way has become of vital importance to him in carning a living. It has been necessary that a few physicians in every county should devise methods by which both the physicians and governmental officials should cooperate together, the physicians supplying medical service and the welfare officers paying the doctors for their services. While the county society gets the credit for the new development, yet the actual work of establishing the coordination has fallen on two or three mem-

Other problems besides the medical care of the indigent are pressing for solution in every county society. There are the medical examination of school children, the treatment of erippled children, child welfare in all its phases, and the care of the blind and deaf. If

a small committee of physicians were assigned to the solution of each problem of a county society, the incubership of that society would be exhausted in the appointments.

It is unthinkable that any considerable number of administrative problems of a county society can be solved by the voluntary service of its incinbers. The only effective solution is the employment of an executive secretary whose principal duty is to carry out the details of the plans of the society and its officers and committees. Now and then a society has been fortunate enough to have a member who has donated five or ten hours a weck to administrative work in the name of the society. The county societies of New York and Kings have medical directors of activitics, while Nassau and Westchester have full-time executive secretaries. Some of the local representatives of the State Department of Health have acted in the names of their county societies. Now and then a county society has had the assistance of a secretary of the county tuberculosis association. All the precedents support the proposal of an executive secretary for every county medical society.

GROUP INSURANCE

One of the most important benefits of membership in the Medical Society of the State of New York is that of sharing in group insurance against malpractice suits. The conditions under which members may share in that protection are printed on page 1228 of this Journal.

The Medical Societies of nearly all the States make provision for protection, and their Journals often call attention to the increasing number of suits brought against physicians for alleged malpractice as an argument for joining the State Medical Societies. Yet the ratio of the number of suits to the total membership in those States is smaller than that in New York. The annual report of the Secretary of the Medical Society of the State of Pennsylvania, for example, lists only thirteen new suits instituted during the year 1932, although the Society has 7,555 members, or slightly more than one-half of the number of members in New York State.

The annual report for Ohio, with 4.920 memhers in its State Society, also shows thirteen snits instituted during the year, a rate far below that of New York.

Although New York State has a high ratio of suits, yet the premium on the indemnity insurance is about that of other States. The principal reason for the low cost of the insurance is the efficiency of the defense offered by the Medical Society of the State of New York. Very few suits have intrinsic merit, and skill in presenting the cases in court results in verdicts for the doctors practically always. Every case is tried by the Society's own counsel, who is familiar with the courts of New York State as well as the physicians. The value of this feature of group insurance cannot be overestimated.

Ohio and some other States which do not include indemnity insurance in their defense against malpractice suits advise physicians to take out insurance against possible judgments, warning them against the risk of insuring with companies which cannot legally write insurance in those The experience of New York State demonstrates the value of the plan of employing its own permanent counsel. Juries are likely to favor a plaintiff when they know that the insurance company, and not the doctor, will have to pay the damages. In New York the Counsel appears as the representative of the Medical Socicty of the State of New York, and therefore of the doctor defendant. A juryman takes a personal interest in the fate of his family doctor.

The group insurance plan of New York State is specially devised for the physicians of the State; and every doctor is urged to adopt it. However, he is to be reminded that cessation of membership in his county society automatically cancels his insurance, but the unused part of the

premium will be returned to him.

MEDICAL PROGRESS

Panaritiums and Phlegmons.-In treating panaritiums and phlegmons, says R. Klapp, the principle to be observed is that of saving the surrounding healthy tissues from necrosis. Early use of antiseptic dressings frequently has the opposite effect, destroying the tissues but not the microorganisms. Friedrich's practice of primary excision of wounds within the first 6 hours is a sound one for all fresh injuries with lacerated margins. When for any reason this cannot be done, dressings of balsam of Peru offer the next best method. Neglect of these measures is responsible for the development of panaritiums which, according to the tissue invaded, are cusubcutaneous, tendinous, periosteal, osseous, or articular. The first two are the most important, since they represent as a rule the beginning from which the infection spreads to the deeper tissues. Spontaneous healing is not to be trusted: the necrosis should be extirpated as early as possible. Klapp makes a double incision, one on each side of the panaritum, and scrapes out all the necrotic tissue with a sharp curette, after which he draws a small strip of rubber through, under the bridge of skin, and ties the ends together with a thread to prevent the escape of the strip. When the dressing is changed, gentle lifting of the rubber will reveal whether there has been retention of pus, which is generally not the case. This method nearly always results in regeneration of the parts after a few Panaritiums of the tendon sheaths are more difficult to recognize, but the patient, if properly questioned, can often tell the exact time, even to the hour, when the pain, previously circumscribed, began to involve the entire flexor side of the finger or even the whole finger. Upon the early recognition of tendon involvement often depends the saving of the tendon and its func-Two incisions on each side of the finger are indicated, to give the pus four avenues of escape. This method has the further advantage of not exposing any tendon and of preventing adhesions between tendons. Bone panaritiums are generally confined to a terminal phalanx, and under x-ray control are as a rule seen to form sequestra that can be removed without sacrificing the phalanx. Joint panaritiums are recognized by circumscribed tenderness, confined to a ring around the joint. Early treatment with irrigations of a 1:1000 solution of rivanol is useful, with removal of any sequestrum that may have formed. Should a phlegmon of the forearm follow a panaritium of the thumb or little finger, the so-called paronychial space must be opened for free drainage by double longitudinal incisions in a volar direction, upon the radius

and ulna.—Münchener medizinische Wochenschrift, July 14, 1933.

Occupational Dermatitis.-W. G. Harvey calls attention to the greatly increased incidence of occupational dermatitis due to the greatly increased use of chemicals in industry and in the home. For the proper diagnosis and treatment of these affections much more than a mere knowledge of skin lesions is requisite. Painstaking and subtle inquiry and a detailed knowledge of industrial processes, as well as of chemistry, is needed, and experts in these lines may have to be consulted. It is regrettable that dermatologists are not in agreement as to the terms they employ. It would be helpful to have an ex cathedra pronouncement of the exact meaning of eczema, as well as of anaphylaxis and allergy. To Harvey eczema connotes a clinical syndrome, a particular form of dermatitis. Eczema in itself is not a full diagnosis. The London Hospital uses two excellent qualifying words—Sequeira's "diathetic" eczema, and O'Donovan's "exogenic" dermatitis. In the majority of cases of exogenic dermatitis there is a history of a capable irritant, the lesion is confined to the seat of its application, and heals quickly when, and only when, the irritant is absolutely withdrawn. In addition patch tests may give confirmatory evidence. On the other hand, a trade dermatitis may give rise to lesions appearing symmetrically, and in regions far remote from the application of the irritant. It cannot be said that we are surely familiar with a diathetic eczema. One of the most difficult problems is to assess the liability where a dermatitis is in part due to occupation and in part to some slight departure from normal of the patient himself-for example, xerodermatous skin. Harvey quotes authorities who claim that there is no such thing as Baker's eczema, that 50 per cent of the supposed cases are sugar dermatitis, and that it is useless to attempt desensitization to flour. Dye dermatitis, on the other hand, is essentially allergic. quency of an occupational cause in cancer of the skin is probably insufficiently recognized. Soot, tar, creosote, anthracene, mineral oils, and the x-rays are known to be carcinogenic. In the treatment of occupational dermatitis the first care should be prophylaxis. Persons whose skins suggest vulnerability should be excluded from skin irritant industries. These include the young and those with delicate looking, "thin" skins. Employers should see that the handling of noxious substances is reduced to a minimum by the substitution of machinery, and should supply all possible facilities to the worker for the proper cleansing

of his skin. Dust should be reduced to the utmost by means of special ventilators. In cases of occupational dermatitis, it is essential that the worker be removed from the irritant. In general, methods of desensitization seem to have met with only limited success.—British Medical Journal, August 19, 1933, ii, 3789.

Some Undesirable Tendencies in Using an Etiological Classification of Heart Disease .-Henry A. Christian, writing in the New England Journal of Medicine, August 31, 1933, ccix, 9, believes that while it is advantageous, whenever possible, to utilize ctiology in the classification of a given disease, an etiological classification may not greatly help the situation, especially if it is allowed to replace other criteria of classification. Something of this sort is developing in the classification of heart disease, where the tendency is to neglect the facts which have been derived from a study of anatomy and pathology. Diagnosis and treatment can be based at the same time on etiology, function, and structure, with a definite advantage over utilizing any single one of these. To make a diagnosis of rheumatic heart disease or hypertensive heart disease does not really help in the treatment of the patient. Until we know the cause of hypertension, we can know but little of what causes the so-called hypertensive heart disease, and, after all, it is very probable that some unknown factor has to enter in to produce cardiac failure even in the presence of hypertension. Much of this applies to arteriosclerotic heart disease, too, to use another term in the etiological classification of these affections. Syphilitic heart disease is a very definite etiological type, inasmuch as syphilis rarely causes other than heart disease with aortic regurgitation. Knowing its cause definitely gives a lead to part of the proper treatment, even though in many of these patients antisyphilitic therapy influences very little the symptomatology and hardly more the progression of the lesion. In cardiac disease associated with thyroid disturbance, diagnosis of this relationship, an etiological diagnosis, definitely brings much help in treatment. In rheumatic heart disease, it is helpful in the management of a given patient to diagnose just what is the anatomical condition of the valve and the degree of deformity of its structure. It is such refinements of diagnosis which tend to be lost at present in the utilization of an etiological basis of classification. Possibly it is this attitude toward diagnosis, which has delayed until very recently the recognition that aortic stenosis with practically no lesion of any other valve and usually accompanied by extensive calcification is not only a distinctive clinical entity but one of considerable frequency of occurrence. If clinicians of today were as diligent as their outstanding predecessors have been in seeking permission for postmortem examination of the patients whom they have followed in their illness,

they would make better anatomical diagnoses, which, interpreted in the light of more recent knowledge of etiology and function would give them a very helpful understanding of their patient's disease and its management.

Angina Pectoris. A Plea for Greater Optimism .- T. Stuart Hart, writing in the American Heart Journal, August, 1933, viii, 6, makes a plea for the more cautious use of the terms "angina pectoris" and "coronary thrombosis" and for a more optimistic attitude toward patients included in these categories. In the mind of the average layman these terms carry the implication of complete and incurable invalidism and sudden death. Physicians make use of the term "angina pectoris" so frequently that it seems as if almost any cliest discomfort may be labeled with this diagnostic tag. It is in the author's experience to see patients who have been told that they have angina pectoris or coronary thrombosis who present no objective evidence whatever of an or-ganic defect of the heart or aorta. The whole evidence offered is a statement of his subjective sensations made by the patient. In many instances an acute attack has not occurred under the observation of a physician. Many members of this group have a history and other evidences of a highly organized nervous system. The evaluation of this evidence is sometimes made more difficult by the patient's subconscious desire to secure sympathy, or to obtain financial relief from the opera tion of a disability clause in an insurance policy. In considering the condition of patients in whom a licart defect is suspected, the psychic element is too often neglected. There are many sources from which psychic trauma may come, such as the various sensations in the region of the heart of which the patient is conscious, the sudden death of a close friend or member of the family which has been attributed to heart disease, the injudicious statement of a life insurance examiner, or most often of all, the unguarded verdict of the physician who has been called in for an emergency. If we are to be of real service to our patients our attitude must be one of guarded optimism; pessimism is out of place. If an accurate prognosis for the individual is impossible one is still justified in assuming that a patient is likely to fill out years of useful living. The author feels that he is warranted in taking this attitude, since he sees from time to time a considerable number of patients in whom there seemed to be a definite diagnosis of angina pectoris or coronary thrombosis and who are living ten or fifteen years after the first attack. Some are doing full work with only occasional discomfort; others are living a life of limited activity with a modest amount of Mackenzie records a total of 33 individuals who lived for more than a decade after the first paroxysm of pain, and at the time the report was published 16 of them were still alive.

While the syndrome of angina pectoris should always be taken seriously, this label should never be attached without due thought and study. Whenever possible this term should be withheld from the patient, for it hangs above him like the sword of Damocles.

Epilepsy in Children.—A study of statistics, says Julius Zappert, demonstrates that in 35-50 per cent of epileptics the attacks began in early childhood, and in 10-12 per cent even in the first year of life. It is still uncertain whether traumatism at birth could be held responsible. ever a child has a convulsion for which no other cause can be assigned, one is justified in suspecting epilepsy. Two types of juvenile epilepsy can be distinguished: a continuous and an interrupted. It is not unusual for an isolated convulsion or a small number of convulsions in early childhood to be followed by a free interval of months or even years before any further disturbance is observed. Cases with irregular intervals of a few months constitute a transition from the interrupted to the continuous type, in which the attacks come at regular intervals of no great length. Frequently the convulsions come at first only in the night, and this may be the case for a period of years, until at length a diurnal attack appears. In many cases the convulsions are of the petit mal type. In another group attacks with varying characteristics may follow one another without any rule of conformity, so that the term variable type may well be applied to them. Much more usual than the typical grand mal attacks with clonic convulsions are the cases with tonic contortions limited generally to certain parts of the body, for example one half of the trunk and face, which, however, gradually pass to the other half, not infrequently ending with a few clonic convulsions. Only gradually is the consciousness lost; rarely is there initial shrill cry; the tongue is seldom bitten, but involuntary micturition is frequent. children report such prodromes as eructations, abdominal discomfort, dizziness, a sensation of sparks before the eyes, tingling of the face and tongue, and an inclination to groan and sigh. The difficulty of diagnosis lies in the fact that even in late childhood children have great and small convulsions from other causes. The syndrome of pycnolepsy, having many but brief attacks, has a very favorable prognosis. Even in true epilsepsy the prognosis is frequently good, especially under uninterrupted luminal treatment given over a period of years. Zappert is inclined to use the term epileptiform convulsions and to commend the case to time and further observation, postponing a positive diagnosis until the decision can be made more easily for or against epilepsy. — Münchener medizinische Wochen-schrift, July 28, 1933.

The Clinical Significance of Diastasuria.— In the Acta Chirurgica Scandinavica of July 28,

1933, Jens Foged states that after making 1099 analyses of the urinary diastase in 160 patients suffering with various forms of icterus, he has observed that the concentration of diastase in the urine does not exceed the normal values in patients with hepatitis and cancer of the pancreas, but that pathologically increased values are present in more than half of the patients suffering with stones in the common duct. The significance of this observation for differential diagnosis is obvious. When one is confronted with a case of icterus and is uncertain whether to make a diagnosis of hepatitis, cancer of the pancreas, or stones in the common duct, an increase in the urinary diastase will, with great probability, indicate the presence of stone in the common duct. It is of course necessary to exclude other possible causes of increased excretion of diastase (primary pancreatitis, epidemic parotitis, etc.), but this will as a rule not be difficult in an icteric patient with suspicious symptoms of stones in the common duct. Unless there are serious contraindications, Foged thinks that an abnormally high urinary diastase is an indication for operation. Even if the stones cannot be revealed by palpation, an exploratory choledochotomy should be performed. Neglect of this exploratory procedure has been chiefly responsible for the overlooking of stones in not a few cases. If no occlusion of the common duct is found, the clinician should not for this reason conclude that he has been mistaken in the result of the diastase test, for a pathological diastasuria is also found in 10-20 per cent of cases of uncomplicated cholelithiasis and cholecy-In this instance, therefore, the diastase test alone does not give sufficient information as to whether common duct stones are present or not. The finding of an increased diastase value, however, speaks so strongly in favor of an occluded common duct that the duct should be explored by all means available, particularly as a choledochotomy does not complicate the prognosis in any decisive degree. But it should be borne in mind that common duct stone does not always cause a pathological diastasuria. The finding was negative in 43 per cent of the author's cases. It is important to carry out a series of daily examinations before reaching a negative conclusion. increased excretion of diastase must be regarded as evidence of a pancreas irritated by the proccesses of the bile ducts, most frequently by retention of the pancreatic secretion due to an obstruction of the passage at the papilla of Vater.

The Influence of an Unsalted Diet upon the Gastric Secretion, and the Clinical Use of Such Diet.—Studies were carried out by Unverricht upon both healthy and sick individuals with reference to the effect of an unsalted diet upon secretion of gastric juice. Such diet is saltfree only in the sense of having had no salt added in its preparation. It is important in prescribing such a regimen to include in the diet a large number

of vegetable substances containing a relatively large amount of sodium chloride. The experiments confirmed Eimer's findings that in most individuals an unsalted diet causes an increase in the total acidity and free hydrochloric acid, that it does not impair the capacity of the stomach for digesting protein, and that pensin secretion remains normal. It thus becomes evident that the secretion of gastric juice is not dependent upon the artificial administration of sodium chloride, and that the small natural content of this substance in foodstuffs is sufficient for the formation of normal gastric juice. For clinical use the composition of the diet need not be so poor in salt as was that of the experimental diet, namely 0.5-1.5 gm. per day, but may reach 2-3 gm. daily. It is permissible to add 1 gm. more on 1 or 2 days each week if flagging appetite or muscle fatigue is observed. The unsalted diet has been used by Unverricht efficacionsly in cases of cardiac insufficiency, cirrhosis of the liver, essential hypertonia, and nephrotic hydrops. One must of course not curtail the use of salt systematically in chronic nephritic patients with hyposthenuria, since diuresis could not then be maintained without the danger of hypochloremia. This applies naturally only to those cases in which the diluting power of the kidneys for sodium chloride is already diminished. Since the extrarenal factors are the most important causes of the edema, and are the ones chiefly influenced by limitation of salt, it is justifiable in every case of edema, be its causes renal or otherwise, to employ this diet. Certain endogenous forms of obesity are favorably influenced by an unsalted diet. The desiccating action of this type of diet makes its use beneficial in certain types of skin affections, such as priiritus, eczema, psoriasis, etc., and also in bronchitis and bronchiectasia. Many cases of obstinate catarrh of the respiratory tract and also the secondary bronchitis of tuberculosis, have disappeared or been greatly improved by its systematic use .- Deutsche medizinische Wochenschrift, August 4, 1933.

Malarial Therapy in Leucemia .- According to M. Trombetti, writing in the Riforma medica of June 24, 1933, Rosenow, who claimed to have had excellent results from malaria therapy in leucemia, had in reality observed only a transitory improvement in one case of myeloid leucemia, and had then desisted from the treatment, considering that infectious diseases in general have an unfavorable influence upon leucemia, the course of which becomes accelerated, although the white blood count and the hyperplasia of the viscera seem at first to regress. In one of Hirschfeld's cases of pneumonia it caused a chronic myeloid leucemia to change into an acute leucemia. Paschkis has recently reported that he employed malaria therapy in the case of a man of 48 who had been syphilitic for a long time and in whom

the cerebrospinal fluid yielded a positive Wassermann reaction despite repeated specific treatments. The white count was 30,000, with 79 per cent lymphocytes and 2 per cent monocytes. On the 16th day the splenomegaly was slightly inereased and the white count was only 7900, with 66.5 per cent lymphocytes and 4 per cent monocytes. Half the lymphocytes were young, immature cells. When, however, the malaria was combated with quinine, the leucocytes rose again to 13,600, with 73.6 per cent lymphocytes and 3 per cent monocytes, which after 7 days became 24,400 leucocytes, with 77 per cent lymphocytes and 1 per cent monocytes. This new observation cannot, therefore, be regarded as encouraging for the malarial treatment of leucemia.

Appendical Oxyuriasis and Appendicitis .-Harold Gordon, writing in the Archives of Pathology, August, 1933, xvi, 2, presents a study of the incidence of oxyuriasis in 26,051 appendices, 311 (1.19 per cent.) of which showed the presence of oxyurids. In the first 20,969 appendixes in this series the incidence was 1.04. It would thus seem that there is an increasing frequency of appendical oxyuriasis. It was found that oxyurids occasionally cause minute mucosal lesions in the appendix. These lesions are accompanied by evidence of living tissue reactionpunctate liemorrhages, slight exudation, and necrosis. The lesions occurred in 12 instances only. To this condition the term "appendicopathis oxyurica" may properly be applied. In 256 instances, the parasites occurred in the lumen of the appendix without producing visible lesions. In 33 instances oxyurids were found in the wall of the appendix. Since none of the sections showed hemorrhage or reaction about the worms in the lymphoid tissue of the submucosa, Gordon is forced to conclude that penetration occurred subsequent to operation. This theory of postoperative migration explains all the observations of previous investigators as well as his own. Not only does it explain the otherwise insurmountable difficulty of complete lack of hemorrhage, but it also makes clear why no one has ever proved the production of inflammation by the carrying of bacteria from the appendical lumen into the tissues or on the bodies of the worms. type of invasion is, therefore, of no pathological or clinical significance. Less direct evidence can be adduced by a statistical comparison of the appendices without worms and those infested with oxyurids. Of the former, 26.37 per cent. showed severe inflammation; of the latter 22.85 per cent. Correction of the general operative group for age to correspond with the restricted age group favored by infestation with oxyurids yields a much higher incidence of inflammation (42.35 per cent.). The material of this study supports the view that oxyurids are not a significant cause of appendical pathological changes.

LEGAL

PHYSICIAN AND PATIENT—PRIVILEGED COMMUNICATIONS

By LORENZ J. BROSNAN, Esq. Counsel, Medical Society of the State of New York.

Some months ago in these columns, we discussed a case in which one of the Justices of the Supreme Court of this State was called upon to rule on the applicability of the privileged communications rule in the case where an autopsy has been performed. The principal case discussed in the article which appeared in the October 15, 1932 issue of this Journal, held that the statutory privilege against disclosure of information by physicians did not apply in the case where testimony as to autopsy findings is sought to be put into evidence upon a trial.

Recently, in another State a closely related question came before the courts, and in that case it was ruled that the professional privilege operated to bar the testimony. The situation precisely was that two doctors were called to attend a dying man and arrived to render aid, after he had passed away, and then made futile attempts to revive him. It is necessary, for an understanding of the case, to set forth the facts.

The deceased was at the time of his death a man of sixty, who weighed over two hundred pounds. He was over six feet tall and was in apparent good health. On the date of his death, he ate his dinner, changed his clothes and then went to his garage to work on his car. He was seen nearly two hours later still working on the car, and about an hour and a half thereafter he was found lying face downwards on the floor of the garage near the car with the engine still running. All of the garage doors were closed. There was some grease on the floor on which he would have possibly slipped and fallen, and there were bruises on his forehead and nose. The color of his face and chest was deeper than natural red. Two doctors were summoned who made attempts to revive him but where unseccessful.

In subsequent litigation the question arose as to whether the deceased had died by external violent and accidental means other than by inhalation of carbon monoxide gas. The question of suicide was not involved. The widow sought to establish by medical testimony, based upon hypothetical questions reciting the conditions under which he was found, that he died of concussion of the brain and cerebral hemorrhage. The defendant sought to establish, by the two doctors who worked

over the deceased, facts indicative of carbon monoxide poisoning. The question as to the admissibility of their testimony, in the light of the professional privilege statute, was taken up on appeal to the highest court of the State. That court decided that the testimony was not admissible, for the statutory privilege applied.

The statute under which the ruling was made was substantially the same as that in New York, reading as follows:

"A licensed physician or surgeon shall not, without the consent of his patient, be allowed to disclose any information or any opinion based thereon which he acquired in attending the patient in a professional capacity and which was necessary to enable him to act in that capacity."

In the opinion of the Appellate Court, the autopsy situation above referred to was discussed and distinguished as follows:

"The case is wholly unlike that of physicians called to perform an autopsy, because in such cases they are not there for the purpose of treating or ministering to the patient but are there merely to determine the cause of death. Most of the cases hold that information obtained by physicians in performing autopsies is not privileged under the statute. *** (the deceased) was probably dead when the doctors began their treatment; but we surmise this because the treatment failed to resuscitate him. We do not know at which precise moment he passed away. Had he been revived, of course anything that these doctors learned in their treatment would have been privileged."

The court in continuing the discussion of the case said:

"It is our opinion that the information obtained under circumstances such as these and the opinion based thereon where, in hope of reviving and resuscitating the patient, doctors examine him and give treatment, is privileged under the statute. They acquired this information in acting in a professional capacity for the purpose of enabling them to act in that capacity, not to determine the cause of death, but to prevent death if possible. If the patient were still alive at the time they commenced the treatment, but died during the process, we think that all would agree that the privilege

covered the situation. How can it be any different when the doctors do not know whether the patient is beyond hope of revivial? It would be an absurd result to say that the privilege depended upon the event rather than on the purpose of the physician. The Legislature could not have intended such a construction. The fact that the result is unfortunate cannot have been intended to terminate the privilege as of the moment of death. The privilege in so far as it relates to objective symptoms would be largely nullified if a physician were compelled to tell what he saw the moment after death occurred."

It should be noted that one of the Judges of the court dissented from the opinion of the majority of the court. He wrote a separate opinion in which he said:

"The purpose of the statute is to protect the disclosures of the living and not at all to make incompetent the appearance of the dead. It is in derogation of the common law, and therefore to be construed strictly rather than liberally. It is not to be extended by unnecessary implication, and I feel that this decision may lead to just that. It occurs to me that in every such case there is for the judge this preliminary fact question: Was the patient dead at the time of the observations concerning which the doctor is asked to testify? A corpse cannot be a patient within the meaning of the statute. So, if the determinative fact question is answered in the affirmative, the doctor should be permitted to testify concerning his post mor-tem examinations. Here it strikes me that any trial indge could have held on the evidence that the patient was dead at the determinative moment, thereby making the testimony admissible."

1227

Our Court of Appeals has stated the necessary elements to bring such a situation under the prohibition of the statute, to be as follows:

"1. The relation of physician and patient must exist. 2. The information must be acquired while attending the patient. 3. The information must be necessary to the physician to act in that capacity."

Should such a situation be presented in this State, the courts would be called upon to decide whether these elements are present. The intention that the relation of physician and patient should exist seems clear, but whether it ever did in fact exist seems open to question.

CLAIMED NEGLIGENT TREATMENT OF SYPHILIS

A young man and his wife consulted a general practitioner, stating to him that they had been married for eleven years and during that time she had become pregnant three times and each time had spontaneously aborted. The doctor became suspicious that both might have syphilis, so he suggested that Wassermann tests be taken. The patients consented and reports were received from the Board of Health laboratories which showed four plus for the husband but were negative for the wife. The doctor informed the man of the reports and suggested a course of injection treatments.

The man came back from time to time to the doctor's office and received a number of injections of neosalvarsan, in addition to which the doctor administered to him two injections of bismuth intramuscularly. patient then stopped returning for treatment to the doctor's office, and about ten days after the last injection the doctor was called to the patient's home, where he found the patient in bed with an extensive dermatitis all over his body. The doctor recognized the condition as an arsenical affection of the skin. He began giving the patient sulfactol injections intravenously and local applications. After ten such injections the patient's condition was gradually improving. At that point a dispute arose between the patient and the doctor, and he never saw the patient again.

malpractice action was commenced against the doctor by the patient, in which the plaintiff complained that the doctor was negligent in his treatment in administering excessive amounts of powerful drugs or poisons, and failing to administer appropriate antidotes to counteract the harmful effects of said drugs or poisons. It was claimed that as a result of the alleged negligence of the doctor, plaintiff was unable to attend to his work for eleven weeks.

The case came up for trial, and the doctor and his witnesses appeared in court ready to try the case. A statement was made to the presiding Judge by the plaintiff's attorneys that the plaintiff could not be located, and a postponement of the case was requested for the purpose of locating him. The defendant's attorney insisted upon proceeding to trial, no legal excuse having been shown to the court for the requested adjournment, and on the motion of the attorney for the defendant the action was dismissed by the court, thus terminating the matter in the doctor's favor, without trial.

NEWS NOTES

GROUP INSURANCE PLAN OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

The unsettled conditions during and after the war brought about a grave change in the attitude of the suing public toward the medical profession throughout the country, and particularly in New York State. Malpractice defense and insurance, which, prior to that time, had been minor factors in the practice of medicine, became increasingly difficult to handle and of vital importance to all medical men. The Medical Society of the State of New York promptly met the new situation by increasing the size and efficiency of its legal defense department, but the insurance companies doing business in this state, either through lack of knowledge or other limitations, were unable to meet the situation to the satisfaction of themselves or those who bought their policies.

It finally became necessary for the State Society to take the lead in devising a way to establish and preserve a stable source of insurance protection for its members. As a result of that leadership the present Group Insurance Plan of the State Society was organized and put into effect in May, 1921.

This undertaking is in effect a copartnership

between the State Society and the Aetna Life Insurance Company of Hartford, operating almost entirely under the supervision of the Society. Through it the medical profession for the first time has been brought into close cooperation with the insurance business; and a high degree of sucess in combating unjust suits and claims has resulted from the combined effort. While loss costs have thus been reduced, the operating costs have also been decreased from time to time so that today, after twelve years of operation, the plan is being conducted at a net cost to members of the Society, both as respects to loss and operating costs, far less than can be supplied by any other insurance company in this state.

From time to time, during the operation of the Plan, questions have arisen which required the adoption of rules by the Society to prevent unequal benefits flowing to a comparative small number of members at the expense of others. At the last meeting of the House of Delegates in New York, in April 1933, these rules were revised and codified for the information and

guidance of members generally.

REGULATIONS GOVERNING MALPRACTICE DEFENSE AND GROUP INSURANCE ADOPTED BY THE HOUSE OF DELEGATES AT THE ANNUAL MEETING, APRIL 3, 1933

Members Not Insured Under the Group Plan

The Medical Society of the State of New York will furnish to its members the services of the Counsel of the Society in actions brought for alleged malpractice, error, or mistake done or claimed to have been done in the legitimate performance of the duties of their profession as physicians under the following regulations:

The Counsel of the Society will serve as attorney in all actions for alleged malpractice, brought against members in good standing, who must be so certified by its Secretary, excepting as follows:

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to membership in the State Society.

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed during a period when they were not in

good standing, according to Chapter XIV, Section 4, of the By-Laws.

Members shall not be entitled to malpractice defense while residing and/or practicing medicine or surgery outside of the territorial limits of the State of New York.

The Society will not undertake the defense of any member who, after consideration by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide, or any criminal act or who has not complied with the recognized ethical laws in regard to these cases.

Members shall agree not to compromise any claim against them, nor to make settlement in any manner without the advice or consent of the Society given through its attorney.

In the event that a member sued or threatened with suit shall, without the advice or consent of the attorney of the Society, determine to settle or compromise any claim against him, he shall reimburse the Society for the expense incurred in undertaking his defense, and in default thereof, he shall be deprived of further privilege of malpraetice defense.

The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims, or awarded by court verdicts, or for making

payments for any purpose whatsoever. Members of the Society desiring to avail themselves of the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing. They shall also furnish the Legal Counsel a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based, giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question, and shall furnish such other relevant information and execute such papers as may be required of them by the aftorney of the State Society.

In the event of any difference of opinion between a member of the Society and the Counsel concerning the eligibility of a claim for defense, or any other matter having to do with malpractice defense or indemnity, all details shall be presented to the Insurance Committee to be referred with recommendations to the Executive Committee of the Council for its decision.

The foregoing regulations are subject to such change as may from time to time be authorized by the Executive Committee of the Council or the House of Delegates.

Members Insured Under the Group Plan

All members in good standing shall be entitled to malpractice defense and indemnity in the Group Plan of Insurance on payment of the premium due on the policy selected; but the amount of insurance protection granted to any member may be limited at the discretion of the Executive Committee of the Council. subject to petition for reconsideration.

When upon the final completion of the defense of any suit or claim it shall appear to the satisfaction of the Executive Committee that the medical procedure, conduct or attitude of the member involved was such that it could not have the approval of competent medical opinion generally and that the continuance of such medical procedure, conduct or attitude would constitute a burden to the Society's Group Insurance Plan more hazardous than that contemplated in what is generally accepted as the competent practice of medicine, the Society shall have the right to

withdraw from such member the privilege of renewal of his indemnity insurance under that Plan. Nothing in this rule shall deny such member a rehearing by the Executive Committee. This rule shall also not abrogate such member's right to subsequent malpractice defense by the Society.

If an assured shall fail to maintain in good standing his membership in the State Society, according to Chapter XIV, Section 4, of the By-Laws, the policy, so far as it applies to such assured, shall be cancelled as of the date upon which he ceased to be a member in good standing. A notice to this effect shall be mailed to the member's last address, and the Company will return upon demand and surrender of his certificate, the uncarned premium due him on account of such cancellation. If the member is reinstated by payment of dues, the former policy cannot again be put in force but the member can secure a new policy under the same conditions as if he were a new member of the Society. This rule shall become operative if and when it is written into the policy of the Group Plan.

The Group Plan of Insurance shall insure a member within the limits of his policy against loss growing out of suits or claims for malpraetice, error or mistake, committed or alleged to have been committed by an insured member in the legal practice of his profession or by any assistant of such a member, whether in institutional or private practice, in the treatment or care of a patient previously seen and diagnosed by such a member and for whom the member has directed a course of treatment or care.

The Group Plan of Insurance shall not cover the liability of an insured member on account of the use of x-ray for therapeutic treatment, the employment of partners, associates, assistants, technicians or nurses to practice medicine in his name independently of his personal diagnosis and specific instructions as to the treatment or care to be given, nor shall it cover the liability which such a member may have by reason of his ownership in whole or in part of any association, partnership, clinic, hospital, sanitarium, dispensary or any enterprise other than his personal practice of medicine therein. The liability for such ownership constitutes additional hazards not contemplated under the Group policy or rates, and losses on account thereof shall not be charged against the experiences of the Group Plan. Protection against these hazards shall, upon request and the payment of an additional premium, be furnished by the carrier by en-dorsement upon members' Group Plan Certificate or under an additional policy of insurance when necessary.

The Group Plan policy shall not cover the liability which an insured member may have on account of injury to patients from causes other than medical treatment, care or advice, nor for injury to persons other than patients from any cause whatsoever. Protection on account of such losses can only be had under general liability or workmen's compensation insurance.

When in the course of duties imposed upon him as a medical officer of the State, or any political sub-division thereof, an insured member shall be required to render medical opinion, he shall be fully protected under his Group Insurance against the consequences of such an opinion provided it shall have been given to competent authority and not made public by him.

All members in the Counties in Greater New York and Rockland, Westchester, Nassau and Suffolk, desiring insurance protection in the Group Plan of the State Society, shall secure that protection through the Authorized Indemnity Representative of the Society, Mr. Harry F. Wanvig.

Members Insured by Companies Other Than the Carrier of the Group Plan

A member who elects to secure malpractice insurance protection from a company other than the Carrier of the Group Plan shall have the same right of defense by the Counsel of the Medical Society of the State of New York as those members not insured provided said carrier is authorized to do business in the State of New York. If the member desires this service under the circumstances, all the regulations as detailed above applying to members not insured under the Group Plan must be observed. At the time the action is

begun, and not later, the Secretary of the Society shall be furnished with the name of the Insurance Company, policy number, date of policy and amount of insurance carried. There shall also be presented at the same time a letter from an authorized officer of the Insurance Company certifying that the Company will assume the full cost of the defense including the fees of the Counsel of the Medical Society of the State of New York similar to those paid by the Carrier of the Group Plan in like instance. Also that he shall not be required to consult with or receive instructions from the Company as to the manner of defense, and that the Company will accept his opinion on the final disposition of the action.

As Companies other than the Carrier of the Group Plan usually compel the holders of their policies to accept defense by the Legal Counsel of the Company concerned, the above would not apply. It is essential, however, that members so insured shall also enjoy the benefits of the services of the Counsel of the Medical Society of the State of New York, if desired; but it is obvious that such service will be restricted by the rule of the Insurance Company cited above. Thus while the Legal Counsel of the Medical Society of the State of New York cannot be required under these circumstances to assume control of the defense or to appear as associate counsel, he shall be ready to render to the Counsel of the Insurance Company, if requested, a consultant's opinion and advice provided the Company concerned will compensate him for this service in the same manner as the Group Plan Carrier would do if the member were thus insured.

All previous resolutions heretofore adopted, pertinent to malpractice claims and defense, are hereby rescinded.

COMMITTEE ON PUBLIC RELATIONS

The regular monthly meeting of the Committee on Public Relations of the Medical Society of the State of New York was held on September 25, 1933, in the Arlington Hotel at Binghamton. There were present Dr. Sadlier, Chairman, and Drs. Hambrook, Cunningham, Johnson, and Ross; and Executive Officer, Dr. Lawrence.

Publicity: The committee discussed the ncessity of informing the members of the County Medical Societies of the functions of their Public Relations Committee, and of the activities in which the State Committee has taken the lead. One suggestion was that special bulletins be prepared and mailed to those particu-

larly interested in the public relations of physicians. Another was that special pages in the Journal be utilized by the Committee.

The committee reached the conclusion that since the Journal itself is designed to carry reports and news to the county societies and their members, provision should be made by each county society at some financial cost if necessary, for sending the news of its activities to the Journal regularly.

There was a discussion on the scope of the work of the county Public Relations Committees, and the items on which they should report to sectional conferences held by the State Committee. The decision was to urge the

county societies to supply the information that was outlined by the Committee as reported in the Journal of August 15, 1933, page 1010.

Fee Scale for Crippled Children: There was a report on an investigation of the fee scale followed by the State Department of Health in authorizing payments for operations on crippled children. An examination of many bills submitted by physicians showed that the fees were satisfactory in the great majority of cases, and in conformity to the fee list suggested by the Committee on Public Relations (Journal February 1, 1929, page 171; and June 1, 1929, page 702). However, the Committee felt that provision might be made for difficult cases and those involving an unusual amount of after care.

Lectures to Medical Students: The details of the lectures to be given to senior medical students by Dr. W. H. Ross, were discussed and the decision was to assign two doctors to accompany Dr. Ross as he gives each address, and emphasize the interest which practicing physicians take in the medical students.

Reference by House of Delegates: There was a preliminary discussion on five subjects referred to the Committee by the House of Delegates, as follows:

- 1. Why so few physicians form a part of the organization or are employed by national health organizations. (Journal, May 1, 1933, page 587.)
- 2. To take steps to prevent the State Department of Health from becoming an agency for the treatment of crippled children. (Journal May 1, 1933, page 597.)

3. In conjunction with the Committee on Public Health and Medical Economics, to draft a desirable Public Welfare Law. (Journal, March 1, 1933, page 288, and May 1, page 599.)

- 4. In conjunction with the Committee on Public Health and Medical Economics, and the Counsel of the State Society, to study the organization of the Public Health Council and regulations of the Sanitary Code. (Journal March 1, 1933, page 289; and May 1, page 599.)
- 5. In conjunction with the Committees on Public Health, Medical Economics and Legislation to study the regulations governing stateaided hospitals, with the idea of insuring their local autonomy. (Journal March 1, 1933, page 290; and May 1, page 600.)

Consideration of these recommendations involves the Committees on Public Health and Medical Education, on Economics, and on Legislation. They will be taken up at the November meeting.

Conference of County Chairmen: The afternoon session was a conference with the chairmen of the public relations committees of the counties in the vicinity of Binghamton.

Broome County: Doctor George S. Lape, of Broome County said that in the triple cities of Binghamton, Endicott, and Johnson, the indigent poor were well cared for. The work was not so well done in the rural sections of the county. There was a nurse in charge of the welfare work in the County outside of the three cities. He stated that "of five thousand ehildren having defects, thirty per cent had been corrected by the Humane Society." All health problems are taken up by the county society. In the cities there are school physicians. In the rural district the health officer frequently does the work. The physicians employed by the Johnson Endicott company do not now do as much private practice as they once did. Considerable study has been made of the water supply of country schools and it was found inadequate.

The Metropolitan Insurance nurses in caring for their sick asked permission to care for contagious diseases. The insurance company asked that they apply to the county society before taking further action on this work, and the opinion of the county society was against it.

They have only part time health officers in Broome County, but they do their work well. All health organizations in the county consult the medical profession before undertaking any The county society has adopted program. resolutions that, in their opinion, it is better to take care of welfare patients in their homes instead of in a county hospital with doctors on salary. It was brought out in the discussion that Broome County is large enough to have an executive secretary of the county society, so as to coordinate all of the activities of the society. About twenty per cent of the profession of Broome County are on salary by the Endicott Johnson Company. When these men practice, they usually do it for less than usual fees. Venereal disease control is carried out by the local health officers. In the care of indigent cases under public welfare, the doctors are paid one dollar in the office, and two dollars in the home, and confinement cases at the rate of twenty-five dollars. The city of Binghamton has five city physicians at a salary of nine hundred dollars each. It was brought out that Binghamton and many other cities have to do this under the city charter.

Chenango County: Doctor B. A. Hall said that the County of Chenango, two years ago, had two county nurses, who helped in clinic, anti-tuberculosis, and all kinds of county health work, but that the county concluded that they could not afford a nurse to do public health work, and now has only the help of lay

people, and what help some school nurses can

give.

In welfare cases the surgeon is paid for laparotomy, sixty dollars, and that indigent cases are well cared for. The county society is opposed to free clinics, but Doctor Hall said that the clinics were necessary to give diphtheria immunization, because doctors do not attend to it. Doctors were paid for venereal disease control work if they wanted to do it. Not many of them wanted to do it. The law says that the health officer must do it if no one else will, but that they cannot get extra fees for it.

The County lost the county nurses because of the need for economy. The relations of the welfare commissioner, the health officers and the doctors are satisfactory. Little school work has been done by the private physicians; it was nearly all done by the school physicians. In the larger towns of the county the defects are quite well corrected. In the smaller places it was not done well. The county society has thirty doctors and the population of the county is 31,000.

Delaware County: Doctor G. B. Maurer reported that the county government would not employ county nurses this year. The county medical society persuaded the Board of Managers of the County Sanitarium to appoint a tuberculosis nurse, which they could do under the law, and this nurse acts as the county They have in the county a central committee having a member each from the County Medical Society, The Red Cross, The Lions Club, The American Legion, and the Churches. This committee meets several times a year for the purpose of coordinating the health work, and to smooth out any difficulties that have arisen. A county health department is not likely to be organized in Delaware County. The efforts of the County Tuberculosis and Public Health Association "do not seem to go well." At the County Sanitarium the County Tuberculosis Committee insisted on having a full time man, but the county society objected to any change being made because the part time man'is satisfactory to everybody.

The relation of the welfare officer to the physician is satisfactory. The surgery is paid for if the patient is in the county hospital, otherwise it is not paid for. The county hospital is in connection with the poor house.

School examinations are rarely done by the family physicians; but the greater number are done by the health officer, or in the larger places by a school physician, and the position is passed around so that every three or four years a physician has the opportunity to examine his own patients.

The Delaware County Medical Society discusses its public relations fully as much as its scientific work. It was apparent from the discussion of Doctor Maurer that the physicians of Delaware County were active in all public aspects of medicine, and were active in their leadership.

Tioga County: Doctor Guy S. Carpenter said that there are twenty-two members in their county society, and four physicians in the county not in their society. At their medical educational meetings, the average attendance for the last course of five lectures was thirtytwo. For economic reasons the county does not now employ public nurses. The county society has four members on the county voluntary tuberculosis and public health committee. The Welfare Commissioner of the county works well with the physicians. Home visits are paid for. Hospitalization is paid for; but since Tioga County lies at the State line, and since the physicians over the State line in Pennsylvania charge nothing, the doctors are unable to charge in Tioga County.

Doctor Carpenter said it may be that the doctors are to blame and perhaps their not being paid was as much that they wanted to have their hospital successful as anything else.

Doctors of Tioga County have not been too cooperative in diphtheria immunizations, and it had been necessary to have free clinics do it.

If the physicians were more interested, they could carry on well-baby clinics. There had been a number of eclampsia cases in the last two years, believed to be the result of a lack of prenatal work. Dr. Carpenter said: "It is too bad that the dollar takes precedence over public health in many cases when the Boards refuse to appropriate money for public nursing. It will never be right until medicine assumes full leadership and full responsibility for public health."

Doctor Hambrook inquired what is being done in the hard of hearing in school work? The answer was, "Not much, and not much is likely to be done until the medical profession more actively undertakes to establish it."

Tompkins County: Doctor Dean Smiley said "Tompkins County has forty doctors and forty thousand population. They have three nurses in the county. The county society is in part opposed to a county health department, but many laymen in the county are anxious to have it.

"There is good care of the indigent poor. The county society has established a scale of fees and each welfare officer has a copy.

"No progress has been made in having the school examinations done by the private physician. All is done by school physicians. It is

well done by the health officer in Ithaca. In he county it is not so well done.

"Annual physical health examinations are not actively advocated by the doctors. uberculosis work in the county has not been very satisfactory, but now the State Tubercuosis Sanitarium located near-by will cure this The relationship of the county situation. society to the lay organizations is satisfactory when the physicians take leadership in them.

Doctor Johnson thought that, since most of us were taught in the medical schools only curative medicine, all older physicians would have to be "born again" before they took up annual physical examinations of well people. He thought that medical colleges should give more definite instructions on physician's examinations of well people, and that the lecture to students this year might stress the teaching of how to make a well person examination.

County Welfare Commissioners: Doctor Lawrence at the close of the meeting presented elippings from several papers showing the interest of county welfare commissioners in conferring with physicians so that the indigent person might have the advantage of being attended by his family physician. There was a general discussion on this subject and they concluded that the family physician could take eare of indigent persons at no extra cost to the tax-payers, and that better service would come by having the patient choose his own physician. In the hands of the family doctor, abuses of medical care would be corrected, and cases would not be placed on medical care unless they were entitled to it.

WILLIAM H. Ross, Secretary

GRADUATE EDUCATION PROGRAM

Dr. Thomas P. Farmer, Syracuse, Chairman of the Committee on Public Health and Medical Education of the Medical Society of the State of New York, has announced the following program of four courses of instruction for the members of County Medical Societies.

Course on Physical Therapy for the Niagara County Medical Society, arranged and given by Dr. Richard Kovacs, 1100 Park Avenue, New York, to be given at 424 Pine Avenue, Niagara Falls, on Tuesdays at 8 P.M.

October 17, 1933-Heat Measures; including diathermy. October 24-Low frequency currents. Electro-diagno-

sis, massage and exercise. October 31-Ultra-violet adiation. Physical therapy in medical conditions.

November 7-Physical therapy in surgical, gynecological and other conditions.

Course on Dermatology and Syphilology for Columbia County Medical Society, arranged by Dr. George M. MacKee, 209 West 59th Street, New York, to be given in Hudson, on Fridays, at 8:30 P.M.

October 13, 1933—The Diagnosis, Cutaneous Mani festations and Clinical Course of Syphilis. Dr. Fred Wise, 200 West 59th St., New York,

October 27-The Diagnosis and Treatment of The Common Skin Diseases (exclusive of eczema, drug cruptions, cancer, and syphilis). Dr. Henry D. Niles, 114 East 54th St., New York.

November 10—The Modern Conception of Eczema with Special Reference to Dermatophytosis. Dr. George M. Lewis, 200 West 59th St., New York.

November 24-Drug Eruptions. Dr. E. Win. Abram-

November 24—Drug Eruptions, Dr. E. Win, Adramowitz, 835 Seventh Ave., New York
December 8—The Diagnosis and Treatment of Cutaneous Cancer and Precancerous Lesions. Dr. George M. MacKee, 200 West 59th St., New York.
December 22—Cutaneous Tuberculosis and Allied Con-

ditions. Dr. Anthony C. Cipollaro, 200 West 59th St.,

Mew York.

January 5, 1934—The Modern Conception of Allergy:
Its Relation to Dermatology. Lantern Slides. Dr.
Marion B. Sulzberger, 200 W. 59th St., New York.

January 19—The Treatment and General Management of Syphilis. Dr. Isadore Rosen, 330 Park Avenue,

New York

New York.

Course on Infections, for the Monroe County Medical Society, arranged by Dr. Frederick T. van Beuren, 630 West 168th Street, New York, to be given in Rochester, at 4:30 P.M.

October 23, 1933-Bacterial Invasion of the Human Body. Dr. Frank L. Mclency, 180 Fort Washington Ave., New York.
October 24-Alkeumatism. Dr. Franklin M. Hanger, Jr., Presbyterian Hospital, New York.

October 25-Infections of the Hand and Arm. Dr. Hugh Auchincloss, 109 East 67th St., New York.

October 26-Infections of Bones and Joints. Dr. Clay Ray Murray, Presbyterian Hospital, New York.

October 27—Puerperal Scpsis. Dr. Benjamin P. Watson, 16 East 90th St., New York.

Course on Gastro-Enterology for the Rockland County Medical Society, arranged by Dr. A. F. R. Andresen, 88 Sixth Avenue, Brooklyn. to be given in Pomona, on Wednesdays.

October 11, 1933-Modern Conception of the Peptic Ulcer Problem. Dr. A. F. R. Andresen, 88 Sixth Ave., Brooklyn, New York

October 18—The Treatment of Various Types of Colitis. Dr. John B. D'Albora, 27 Eighth Avenue, Brooklyn, New York.

October 25-The Diagnosis and Treatment of Gall Bladder Disease. Dr. A. F. R. Andresen, Brooklyn,

November 1-Gastro Intestinal Manifestations of Food Allergy. Dr. Frederick Schroeder, 290 Park Place, New

November 8-Gastro Intestinal Carcinoma. Dr. A. F. R. Andresen, Brooklyn, New York,

FIRST DISTRICT BRANCH

The Twenty-Seventh Annual Meeting of the First District Branch of the Medical Society of the State of New York, was held on Wednesday, October 11th, 1933, in Valhalla, in the Grasslands Hospital,—the County Hospital of Westchester County. There were 170 members registered. The meeting was called to order by Dr. S. J. Kopetzky, Vice President.

Dr. Andrew A. Eggston, President of the Medical Society of the County of Westchester, welcomed the members to the Hospital, which is not only the tuberculosis hospital of the County, but is also a general hospital for the treatment of the poor who suffer from any disease.

Dr. Eggston described the progress which the Westchester County Medical Society had made in perfecting an organization by which the physicians are able to exert their proper influence in controlling the methods of bringing medical service within reach of every person in the County. Only as the medical profession provides all the services that the people need, and as he receives an equitable reward, can the individual physician prosper. The Westchester County Medical Society, with 55 members, has taken an important step in employing an executive secretary who should attend to the details of the relations of physicians to other organized bodies engaged in public health. Concerning the executive officer, Dr. Eggston said:

"Voluntary management is no longer sufficient to cope with all the problems which confront the medical organizations. During the past year we have accomplished many things for the solidarity of our local society, and the very essence of our success has been the employment of an executive secretary whose duty is to promote the welfare of the medical profession which supports his position."

A morning scientific session was held on the general subject of cardiac arrhythmias. Dr. James F. Rooney of Albany, discussed the subject, "The More Common Cardiac Arrhythmias.—their significance and treatment"; while Dr. Frederic C. Conway, also of Albany, gave a paper on "The Use of Quinidine Sulphate in Cardiac Arrythmias."

At noon an operative clinic was held in the operating amphitheatre by Dr. George C. Adie, Director of Surgery in the Grasslands Hospital. Dr. Adie demonstrated the operation of thoracoplasty on a tuberculous patient, explaining the indications for the operation and the results which may be expected from it. The passed a luncheon in the Hospital at one is passed a C. Knight Deyo, President of the years a physic his own patient.

First District Branch, introduced some of the officers of the State Society.

Dr. Frederick H. Flaherty, President, discussed some of the commendable developments in the participation of the State in the distribution of medical services, particularly the provision that medical services to the indigent and worthy poor should be given by family doctors on a fee basis. Official visits to the medical societies throughout the State had revealed a growing cooperation between physicians and the welfare officers, so that working agreements had been already reached in over half of the counties, although both the physicians and the welfare officials were unprepared only a year or two ago. The realization of the mutual responsibilities of both the medical profession and governmental officials in the care of the indigent will lead to their better cooperation along other lines.

Dr. Daniel S. Dougherty, Secretary, received a hearty ovation as he spoke of the kind remembrances of the members during his recent illness. Dr. Dougherty spoke of statements in the daily press that medicine had gone backward; but he was certain that it had progressed everywhere, although not always along the lines advocated by non-medical leaders.

Dr. Orrin S. Wightman, Editor, appealed to the officers of the county medical societies to send news of their activities to the Journal in order that the profession might profit by their experience.

Dr. James E. Sadlier, Chairman of the Committee on Public Relations, urged committees of the county societies to make contacts with the local governmental officials, and the lay welfare organizations, in order that the medical profession might secure the adoption of proper methods of distributing medical services to those who need assistance in obtaining it.

The program of the scientific session in the afternoon consisted of three features:

Dr. Lewis M. Hurxthal, of the Lahey Clinic, Boston, Mass., showed motion pictures illustrating normal and abnormal cardiac mechanism and electrocardiograph.

Dr. Howard Lilienthal, of New York, gave an illustrated lecture on recent types of operation in pulmonary tuberculosis.

An illustrated lecture on the management of tuberculosis cases under collapse therapy was given by Dr. J. Burns Amberson, of New York

The meeting was a decided success from a social as well as scientific standpoint.

FIFTH DISTRICT BRANCH

The twenty-seventh annual meeting of the Fifth District Branch of the Medical Society of the State of New York was held in the High School Auditorium, Oswego.

The Fifth District is composed of seven county societies in the north central part of the State, whose memberships are as follows:-

Herkimer	43
Jefferson	86
Lewis	18
Madison	
Oneida	
Onondaga	
Oswego	44
Total	741

There were 110 members in attendance, and the President, Dr. Edward R. Evans of Utica, presided.

The following officers were elected:

President: William A. Groat, Syracuse. First Vice-President: LeRoy F. Hollis,

Lacona. Second Vice-President: M. M. Gardner, Watertown.

Secretary: Fred C. Sabin, Little Falls. Treasurer: Hermann G. Germer, Canastota

Dr. F. H. Flaherty, President of the Medical

Society of the State of New York, called attention to the major problems now confronting the medical profession, especially the relation of physicians to the medical relief plans of the State of New York.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education of the State Society, discussed some of the public health problems with which the physicians of New York have to deal, and described the graduate courses conducted by the State Society.

The following program of scientific session was carried out:

"The Treatment of Hernia by the Use of Fascia; and More Especially Human Preserved Fascia," Harry W. Vickers, M. D., Little Falls.

"The Results of Biliary Tract Surgery," Allen O. Whipple, M.D., Professor of Surgery, Columbia University.

"The Management of Uterine Bleeding," Thomas P. Farmer, M.D., Syracuse.

of Puerperal "Present-Day Conceptions Sepsis," Benjamin P. Watson, M.D., Professor of Obstetrics and Gynecology, Columbia University.

"Facts Concerning the Temporary Emergency Relief Administration," James N. Vander Veer, M.D., Albany.

FRED C. SABIN, Secretary.

ONTARIO COUNTY

The July Bulletin of the Ontario County Medieal Society has the following description of the third quarterly meeting of the Society.

The meeting was held in the Lafayette Inn, Geneva, on July 11, 1933, with twenty-four members present, and Dr. Harry M. Smith, President, in the Chair.

Dr. Adrian S. Taylor was elected to membership.

Dr. S. A. Munford, of Clifton Springs, Chairman of the Committee on Medical Economics, discussed some of the details of the relations of physicians to the Welfare officials of the County. (These relations are described in the Journal of August 1, 1933, page 934.)

The chairman also urged the members to cooperate more actively in making a survey of the incomes of the physicians of Ontario County, so that the Society would have tangible evidence of the actual cost of giving medical service to a

patient.

Dr. W. S. Clapper of Victor, Chairman of the Public Health Committee, reported on diphtheria immunization, calling attention to the necessity that school districts should furnish a eensus of the children. He also said that the superintendent of public schools would meet with the Public Health Committee in the near future and plans would be perfected whereby a much larger proportion of the children would be immunized than has been possible heretofore.

There was a general discussion on the subject of a revision of the fee bill. The President was authorized by vote to appoint a committee to carry out the necessary investigations and to make recommendations at the autumn meeting. Drs. C. H. Jewett, T. W. Maloney and J. W. Howard were appointed to serve as this com-

Dr. Grove spoke of the activities of The Geneva Academy of Medicine and the plans for the Winter. He outlined an attractive program and extended a cordial invitation to the members of the county society to attend the meetings and to hecome members of the Academy.

The scientific program consisted of a paper on "Trichonoma Vaginalis" by Drs. George M. Gelser, and George W. O'Grady of Rochester.

BOOK REVIEWS

INFANTS AND CHILDREN. Their Feeding and Growth. By Frederic H. Bartlett, M.D. 16mo. of 409 pages. New York, Farrar & Rinehart, Inc. [c. 1932].

This book should serve as an excellent guide for intelligent parents in the care of infants and children. It is not too technically worded, yet it answers the questions of many parents specifically. The author seems to have a keen insight into the psychological makeup of both child and parent, for he suggests treatments adaptable to the home, and even suggests what to tell the child in order to have success. There is an excellent chapter on habits and his method of solving the problem of the child who won't eat is very logical.

Of the many guide books for parents in the care of children, this book should be very valuable because of its sound logic and its reasonable explanations and sug-gestions for treatment. It is packed with good ideas for the physician, too, which are the products of the author's years of experience with children.

DAVID EDWARD OVERTON.

OPERATIVE SURGERY. By ALEXANDER MILES, M.D., and D. P. D. WILKIE, M.D. Octavo of 590 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$5.25. (Oxford Medical Publications.)

The scope of this book on general surgery, while not covering all the ground of operative surgery, has been written to provide for the needs of undergraduates in medicine, house surgeons and men in general practice where minor operations are performed in the office. The descriptive work in this volume of 590 pages is clear and concise. There are 321 illustrations, which is a large number for a publication of this size. The methods which have been selected for description are those most generally favored by the various contributors to this work, and the text represents, in a general way, the present-day practice in the Edinburgh School of Medi-

This volume should prove a valuable contribution to R. F. H. the young physician.

INHERITED ABNORMALITIES OF THE SKIN AND ITS APPEN-DAGES. By E. A. COCKAYNE, M.D. Octavo of 394 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$8.00. (Oxford Medical Publications.)

This exceptional book covers a field that has had only slight attention from other medical authors. It covers the subject thoroughly and in great detail. Many of the subclassifications cover abnormalities of which only one or two appear in the literature. In each case the ab-normality is carefully and completely described, and then its connection with inheritance is discussed. Altogether, this work is very much worth while and one that should be in the library of every dermatologist. It brings to-gether in one book an immense amount of research and makes it available in such a manner that it can be consulted readily and quickly. tion and commendable in every way.

John C. Graham. sulted readily and quickly. It is a valuable contribu-

TEN YEARS OF OBSTETRICS AND GYNECOLOGY IN PRIVATE PRACTICE. By John L. ROTHROCK, M.D. Octavo of 209 pages. New York, Paul B. Hoeber, Inc., 1933. Cloth, \$3.00.

A curious rather loosely knit record of ten years experience in the private practice of obstetrics and gynccology. An interesting clinical report of the author's man-

agement of 1750 obstetrical cases, and 1345 gynecological cases. The obstetric series covers a wide range of conditions; the gynecological list of operations includes many cases which hardly come within the sphere of a gynecologist. Discussion of procedures is intentionally superficial, and no attempt is made to consider any subject broadly. Purely a personal record, the author shows good results, although his methods often differ widely from generally accepted practice. Of no value to the specialist, it is difficult to appraise its practical value.

CHARLES A. GORDON.

MEDICAL CLINICS OF NORTH AMERICA. Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): cloth, \$16.00 net, paper, \$12.00 net.

Vol. 16, No. 1, July, 1932. (Philadelphia Number.) There are two clinics in this issue of the Medical Clinics which are especially worthy of the physician's attention. In reference to injuries to the spine the author states-"I have never seen a case operated upon in which anything was done by the surgeon to hasten recovery." Also -"I have seen patients with spinal cord disease and signs of a complete transverse lesion lasting for weeks ultimately recover entirely." There are other remarks tending to disparage surgery in spinal injuries.

Three cases of acute gastric ulcer with complete medi-

cal cure, as demonstrated by roentgenological study, are

also reported.

Phenylhydrazine seems to be the accepted method of treatment in Vaquez disease at the present time, not because it has any distinct virtues, but because nothing has

as yet been found to be very helpful for that disease.

We are advised to avoid drastic reductions in the blood sugar level in old diabetics lest undernutrition of the heart muscle in the presence of coronary disease lead EMANUEL KRIMSKY. to serious consequences.

Vol. 16, No. 2, September, 1932. (Chicago Number.) This number consists of a symposium on diseases of the heart, the vascular system and the kidneys. It is a Chicago Number, the contributors being mostly from that city's medical schools and hospitals. Beginning with congenital heart disease in infancy, it discusses cardiac conditions through adult life and senility. All the chapters are clinical, simply presented and appeal directly to the general practitioner, who undoubtedly will greatly benefit by their study. Concluding the monograph are chapters on pneumonia, peptic ulcer, including its mucin treatment, ascites, poliomyelitis, carbon monoxide poisoning and carcinomata and cysts of the pancreas.

JOSEPH BENDETSON.

Vol. 16, No. 3, November, 1932. (University of California Number.) This issue is more than a series of case reports. While in every instance clinical records serve the basis of the text, we find disease interpreted in the light of disturbed physiological function. In the same way, therapeutic measures are recommended on the basis of logical deductions.

The entire book is confined to lectures given by Doctor Meakins of McGill University during a visit to the University of California in 1929.

Doctor Meakins deals with common clinical conditions and for that reason his method of approach should be of especial interest. The topics include tetany, acute rheumatic fever, nephritis, tuberculosis, hypertension and arteriosclerosis. There is nothing sensational about what he has to say but he leaves one with the constant

impression that an examination is more than a mere recording of data but requires a searching and an analytical interpretation of the entire picture.

Vol. 16, No. 4, January, 1933. (Boston Number.) Minot tells us that certain persons with prolonged coagulation time of their bloods who are usually diagnosed as cases of hemophilia are in reality sufferers from a dietary deficiency. He describes a case in question which responded slowly but surely to a strict but specific dietay regimen and on this therapeutic response he made his diagnosis. The importance of diet as a sole factor in the therapy of this and other apparently unrelated conditions should therefore be of especial interest.

Christian maintains that well-elubhed fingers in the absence of a chronic pulmonary lesion such as bronchiectasis should justify a congenital etiological basis for the cardiac disorder. In another chapter in this issue Blotner tells us just the opposite, namely, that in subacute bacterial endocarditis—an acquired condition—marked clubbing of the fingers is to be looked for.

In the chapter on goiter the writer maintains that "a drop in the basal metabolism in response to iodine and a rise when its administration is stopped constitutes pathog-nomonic evidence of Graves' disease." Joslin and his associates offer a statistical study on Diabetic coma. There is a valuable chapter on nitroglycerin collapse a condition with which many a physician has been un-pleasantly surprised. That a typical, acute arthritis may in reality be part of a cancer or of a syphilis pic-ture is discussed. For agranulocytic augina pento-nucleotide seems at present to be the best agent even though its action is uncertain.

Vol. 16, No. 5, March, 1933. (Baltimore Number.) This number should appeal to the general practitioner because it stresses clinical medicine in simple every-day language and because it describes the trials and successes which we practitioners encounter every day. It espe-cially serves to keep us reminded that every symptom, however trivial it may seem, demands an exhaustive investigation.

And so we find a chapter on diarrhoea, one on epileptiform seizures, one on various gastric symptoms, and one on obesity. The chapter on status lymphaticus is by no means convincing and serves to revive the moot issue as to "What is status lymphaticus?" There is some encouraging news about the response to trichlorethylene inhalations in cases of trigeminal neuralgia. For cases of ehronic cardiospasm the Plummer hydrostatic dilator is favored by the contributor on that subject.

There is nothing seusational about any of this information and many a reader will feel reassured that his own methods are beyond reproach.

Vol. 16, No. 6, May, 1933. (Mayo Clinic Number.) While progress has been monumental in various fields of medicine it has carried with it certain insidious ele-ments of danger. On that account contributions which aim to remind us of such inroads should be welcomed. Alvarez tells us that this "training of plusicians has developed the bad habit of expecting to find in each patient something organically wrong that can be cured by medicine or surgery." He places the responsibility for such a vicious state of affairs on the deans of medical colleges. The deans might easily shift it to higher-

In the chapter on Colitis, a therapeutic regimen is prescribed in which diet alone is emphasized. Colon irrigations, drugs, and vaccines are looked upon with disfavor.

The estimation of the amount of indican in the blood is said to be of definite value in severe cases of renal insufficiency.

y one

There is a short but valuable article by Plummer warning the physician never to rely on a single basal metabolic determination. Case reports showing a favorable decline in the basal metabolic rate without the use nf iodine are presented. Only when the rate is consistently high on repeated examinations should a diagnosis of hyperthyroidism be made.

EMANUEL KRIMSKY.

A STANDARD CLASSIFIED NOMENCLATURE OF DISEASE. Edited by H. B. Logie, M.D. Compiled by the National Conference on Nomenclature of Disease. 12mo of 702 pages. New York, The Commonwealth Fund, 1933. Fabrikoid, \$3.50.

The "Standard Classified Nomenclature of Disease" is the result of at least three years of careful work by the National Conference on Nomenclature of Disease, Dr. George Bachr, Chairman of the Executive Commit-tee, and Dr. H. B. Logic, Executive Secretary. The basic plan of classification of nomenclature de-

pends upon a dual method of classification-etiological

and topographical (anatomical).

The list is somewhat larger than previous nomenclatures of disease and is, therefore, more complete. There is an alphabetical index at the end of the volume which greatly facilitated employment as a reference volume by clinicians, public health officials and record room clerks A system of code numbers, for disease, is supplied for optional use, especially designed for large hospitals, the federal services, insurance companies and municipal health departments, which employ a punch card system for tabulating more speedily, statistics.

The volume is very attractively gotten up, printed with good type and paper. The nomenclature has been approved by a long list of national organizations headed by the American Medical Association and should be a long step forward in the direction of uniformity in medical terminology.

E. P. MAYNARD, JR.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgcry. Series 1932. Chicago, The Year Book Publishers, [c. 1933]. Urology, edited by John H. Cunning-Ham, M.D. 12mo of 464 pages, illustrated, Cloth, \$2.25.

This little work is a storehouse of information compiled by an outstanding leader in the field. It represents the urological literature, both American and foreign, covering the entire field of Urology for the year 1932. The majority of important contributions are presented together with a concise consideration of each. One is impressed with the tremendous growth of the specialty during the past year as evidenced by the mass of accumulated material.

It is to be noted further that dermatology and syphilology are not included and that these subjects are oc-

cupying an increasingly limited field among Urologists.

There is a great deal of value in this book. As a matter of fact, in the reviewer's lumble opinion, this type of work will have a tendency to replace the former stereotype text-book method. One can conveniently ob-tain the most up-to-date information and, as each author rain the most up-to-date information and, as each author is quoted, he can readily refer to the general literature, if he so desires. The indexing of reprints of current contributions is a problem and this little book fills a valuable niche in keeping abreast of the most recent contributions. The work is indexed by subjects as well as by authors. It is worthy of note that very few pages are devoted to a consideration of groupers. are devoted to a consideration of gonorrhea.

Augustus Harris.

wa--.

OUR NEIGHBORS

THE NEW ENGLAND MEDICAL COUNCIL

The Rhode Island Medical Journal of August contains the report of Dr. F. T. Fulton, delegate to the New England Medical Council, which is composed of delegates from the six states, meeting twice a year. Dr. Fulton reported as follows:

The New England Medical Council was established in 1926. Each year our Association sends to the meetings of this Council three delegates, the President and Secretary of the Society being

delegates ex-officio in addition.

"Apparently there has been no report before the House of Delegates of these meetings since the Council was established. It is the custom of the Council to hold two meetings each year. The proceedings of these meetings are published in full in the New England Medical Journal. Members of our Society are probably less familiar with these proceedings than of those of other states, inasmuch as we have our own medical journal, and the New England Medical Journal is probably not so universally read.
"Inasmuch as I automatically go off the com-

mittee at the coming annual meeting, I have been asked to give some report of the Council meetings, a thing which ought to be done at least

once a year.

"This report must necessarily be quite sketchy, and will cover the meetings of the last three years, most of which meetings I have attended.

"The meeting on February 19, 1930, had for the subject of discussion, 'The Relation of Clinics and Health Association to the Medical Profession.' Papers were read by Dr. Roger I. Lee of Boston, Dr. D. L. Richardson of Providence, Dr. George Blumer of Yale, and Dr. George H. Bigelow of Boston. At this meeting there were an unusual number of papers. More commonly there is one paper which presents the subject for discussion in a general way, and a more or less general discussion follows.

"September 25, 1930, 'The Practice of Medicine in Industry' was the subject. This paper was read by Dr. Harold W. Stevens of the Harvard School of Public Health, and was discussed

by Dr. Cecil Drinker, Professor of Physiology at Harvard, Dr. R. S. Quinby of the Hood Rubber Company, and Dr. W. Irving Clark, Surgeon

to the Norton Company, Worcester.

"On February 12, 1931, Herbert E. Locke, Esq., of Augusta, Me., attorney for the Maine Medical Association, read a paper upon 'The Malpractice Suit; Why and Wherefore.' The Malpractice Suit; Why and Wherefore.' subject was very ably presented from the point of view of the legal profession rather than that of the medical profession, and was followed by a very interesting discussion.

"The next meeting was on December 1, 1931, at which time Dr. Stephen Rushmore of Boston presented a paper on 'The Medical Practice Act.' At this meeting the health officers from all the states of New England were present and there was a very general and quite a satisfactory dis-

cussion of the subject.

"March 10, 1932, the discussion of Mr. Locke's paper on 'Malpractice Suits' was carried over from the meeting of a year previously. In the evening of that day, Dr. Iago Galdston of New York, and Dr. Morris Fishbein of the Journal of the American Medical Association, spoke upon the subject of 'Medical Publicity by Organizations and Individual Physicians.'

"At the October meeting in 1932, the question of Post-Graduate Education, with special reference to the Treatment of Fractures, was discussed particularly by Dr. Charles L. Scudder. His plan was approved by the Council, but no special method of financing this plan was sug-

gested or adopted.

"At this meeting there was a vote of protest; sent Dr. Edward H. Cary against government aid, to the soldiers of the World War for surgical or medical services for disabilities of non-service origin.

"In February of this year the topic was 'Medical Economics, with particular reference to the Cost of Medical Care.' The papers and discussions were good, but did not lead to anything more definite than such has in the past."

A HEALTH INSURANCE COMPANY IN MINNESOTA

The September issue of Minnesota Medicine has the following item on the rise and fall of a health insurance company in the State:

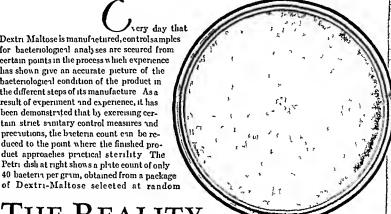

"Medical, surgical and dental service for $$1.5Q_{h}$, smonth. This amount per individual

A curious rather if and dentist, the overhead of perience in the private or insurance and provide ogy. An interesting clii.

presumably satisfactory service. What individual would not gladly pay this small amount each month if he thought he could thus satisfactorily care for his doctor's and dentist's fees. Satisfactory medical service cannot be supplied for what would be the doctor's share.

RAHWAY, N. J.

(Continued from page 1238)

"But this was not the reason why the charter of the Pioneer Mutual Health and Benefit Insurance Company was declared forfeited by the District Court of Ramsey County. Here was another instance of a corporation proposing to practice medicine. A corporation is not an individual, but is a creation by the legislature and thus according to law is not a natural individual and cannot practice in the State of Minnesota. Physicians and dentists were to

have been hired at low salaries and one can readily imagine that the insured would have obtained just about the service paid for. The proposition is just another example of an attempt to take advantage of the times and commercialize the medical and dental professions on a ridiculously low financial basis. The outcome of the suit which was conducted by the Attorney General with the assistance of Mr. F. Manley Brist, will be to the benefit of the public, and the medical and dental professions.

HEALTH INSURANCE IN MINNESOTA

The September issue of Minnesota Medicine contains the following editorial on health insurance, and its prospects in St. Paul:—

"The one criticism to all insurance is the high overhead which seems to accompany most types of insurance. For instance, it costs most of the large life insurance companies about as much to furnish insurance as is paid out in benefits. In the case of life insurance there is little chance for quibbling. When a man is dead, he is dead. Life insurance companies have operated long enough to provide accurate statistics and rates can be accurately determined. Not so with accident and health insurance. A man may think he is sick or think

he is disabled from an accident and attempt to collect from his insurance, whereas he would be able to carry on if he had no insurance coverage. This uncertainty and difference of opinion which frequently leads to legal suits have made sickness and casualty insurance anything but profitable for companies which have entered this field.

"Hospital insurance is in its infancy. There is little experience upon which rates can be established. It has much of the uncertainty of health and accident insurance. The issuance of individual policies at random is too likely to include a high percentage of those suffering

from chronic ailments. For these reasons the larger insurance companies have not entered the field. A recent questionaire was sent to some of the representative insurance companies requesting their attitude to hospital insurance. None of them was interested.

"A group hospital insurance plan which includes all the hospitals in a community is quite different from one instituted by a single hospital in the city. The medical profession has rightly opposed the adoption of the plan by the individual hospital, which is bound to affect the relation of the patient to his physician.

"The plan proposed by the hospitals in Saint Paul aroused some discussion in medical circles and received some mention in our columns The organization is in operation, but has shown a slow growth, doubtless due in large part to the fact that nobody has money for anything. It is thought that by keeping the overhead down to a minimum, avoiding the high overhead incident to most insurance, and limiting the policies to groups of wage earners, the rate of nine dollars a year will be sufficient.

"The profession will watch with considerable interest the progress of hospital insurance, which is more or less in the nature of an experiment. Any measure which will relieve the unequal distribution of the cost of illness should receive the support of the profession as

well as the public."

MEDICAL ECONOMICS IN OHIO

The annual report of the Committee on Economics of the Ohio State Medical Association is contained in the Ohio State Medical Journal of September, which says:—

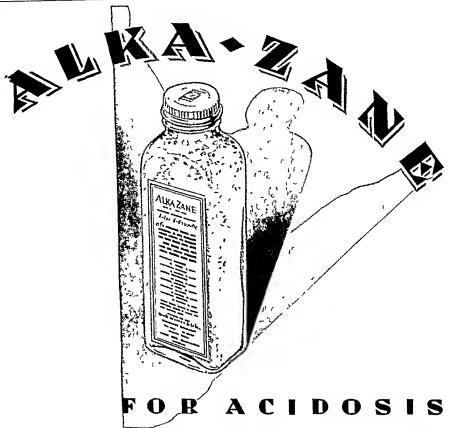

"During the past period of unrest and uncertainty, numerous efforts have been made to overthrow completely the existing system of medical practice. Unjust and unfair criticism has been leveled at the profession, arousing distrust on the part of some factions of the

public. "Unwisely, many persons have been led to believe that medical care can be measured solely in terms of dollars and cents. The economic and organization aspects of medical care have been greatly overemphasized. On the other hand, the fact that quality and individual application is the fundamental element in any system of efficient medical care has either been ignored or treated with indifference.

"During the past 12 months or so, we have been literally swamped with outside advice as to how to meet our problems and those of the public. We have been urged to organize ourselves into large groups for the purpose of furnishing the public with the benefits of cura-

"Hospitals have been urged to convert themselves into gigantic medical centers and to inaugurate periodic payment plans to enable patients to meet the costs of hospitalization; but there has been no guarantee that such a plan would not place the hospital in direct competition with the physicians of the community or that the insurance plan thus set up would not ultimately be extended to include both the services of the hospital and of the physicians on the hospital staff, causing a breakdown in the relationship between physician and patient.

"No single, all-inclusive, inelastic 'plan' will meet all the situations and conditions arising from disabling sickness or injury. Most of the problems of medical care are essentially local and practical, not general and theoretical. No single artificial program can be made to fit the conditions in all communities. There are no safe cut-rate, shortcuts to efficient and effective medical service. Facilities needed to provide adequate medical care in one community may be unnecessary in others. Such facilities should be established on the basis of local conditions and needs.

"Your committee is of the opinion that it is the duty of every county medical society to see that its members are fully and accurately informed about the important medico-social questions confronting the profession. Every society should have a special committee whose duty is to assist the officers of the society in disseminating such information to the membership and in arranging programs for the discussion of economic questions.

"Moreover, it is important that every county society have an active committee on public relations, on economics, or civic affairs to contact and cooperate with official and non-official

DISCIPLINING PHYSICIANS IN MASSACHUSETTS

The July 6th issue of the New England Journal of Medicine contains the annual report of the Committee on Ethics and Discipline of the Massachusetts Medical Society; which is somewhat similar to the Grievance Committee of New York. The report reads:-

"Five meetings were held during the year, and numerous conferences and investigations were conducted by the Chairman and other members of the Committee relating to complaints received against 21 Fellows of the Society. Hearings before the full committee were accorded to seven Fellows, two of whom appeared twice. The accusations made ineluded:

Unethical advertising
Neglect of patients
Fraudulent practices 6
Instigating lawsuits 2
Illegal surgery
Miscellaneous 4

"The resignation of one Fellow was asked for and obtained because he had lent his professional name and influence to the exploitation of a fraudulent remedy; another Fellow was deprived of the privileges of Fellowship under Chapter I, Section 8, Clause (c) of the By-Laws, having been convicted in a court of law of a crime involving moral turpitude. A statement was made by the Chairman, of the circumstances attending these two eases, before the Council at its stated meeting on February 1, 1933, and need not be repeated (See Proceedings of the Council, Massachusetts Medical Society, February 1, 1933. New England Journal of Medicine, February 23. 1933, p. 420.) Another Fellow, after investigations and hearings over a series of years, has been asked to resign on account of conduct unworthy of an honorable physician; you have accepted his resignation today.

"It will be noted that the matters which have come before the Committee have not been so numerous, and perhaps not so serious (Continued on page 1246-ndv. xrni)

What uses do you make of MINERAL OIL?

BECAUSE the action of mineral oil is lubricant and not purgative, it is free from the harmful results which the constant use of laxatives often leaves.

Because Puretest Mineral Oil is very highly refined and is of uniformly high viscosity and specific gravity (up to .895 at 25°C), it insures a maximum of penetration and lubrieating action which makes it a valuable aid in many conditions. You will be pleased with its action in the following:

- 1. OCCASIONAL LAPSES OF THE USUALLY NORMAL BOWEL.
- 2. WHEN COLON IS INJURED BY CHRONIC CONSTIPATION. The bowel erippled by excessive use of harsh laxatives is apt to love some of its natural lubricating mucus. Puretest Mineral Oil is an excellent substitute.
- CHRONIC GASTRITIS, CASTRIC ULCER, ETC. In any such cases where a bland diet is required, Puretest Mineral Oil is both soothing and effective.
- 4. IN SPASTIC COLITIS or where there is a tendency to spasm in the colon or in any painful form of constipation.
- 5. IN THE CONDITION CALLED "AUTO-INTOXICATION." Many authorities believe this depressing condition is caused by decomposition proteid products in the intestinal tract. Purctest Mineral Oil is highly absorbent of these

, •, 204 1

(Continued from page 1245—adv. xvii) as in the preceding year. The Committee believes that it has been useful in serving as a clearing-house for complaints and criticisms, for the airing of grievances and the exchange of views, and feels that the frank and personal

discussions which it encourages are helpful in promoting understanding and agreement. As in former years, our investigations are quite as apt to clear Fellows of the Society of unjust charges and criticisms, as to disclose facts justifying remonstrance or discipline."

JOURNAL OF MINNESOTA

The annual report of the publishing committee of the Minnesota State Medical Association is contained in the September issue of Minnesota Medicine, the official publication of the Association, which gives the receipts and expenses of the Journal for the year 1932, as follows:

Receipts:	• • •
Advertising Other sources	\$7,344.88 821.22
Expenses:	\$8,166.10
Printing Commissions	\$10,743.86 965.30
Net cost	\$11,709.16 \$3,543.06

The deficit is covered with an allocation of two dollars per member, or \$4,204.00. No rents or salaries are charged to the Journal.

The House of Delegates discussed the policy of the Journal. President Pearce said:—

"There has been considerable difference of opinion as to how much of our State Medical Journal should be devoted to economic problems, how much space should be devoted to economics, and how much should be devoted to science. I am sure that the Editing and Publishing Committee will be very glad to have the House of Delegates act on the recommendation of the Reference Committee.

"As I understand, the Reference Committee are advocating that more space in *Minnesota Medicine* be devoted to publishing matters of economics. Is there any discussion on this

report? If there isn't, the Chair declares that it is the sense of the House of Delegates that this recommendation of the Reference Committee be accepted."

Dr. W. F. Braasch said .-

"I am a member of the Reference Committee. I would like to know how some teeth can be put in that recommendation because a similar suggestion has been made year after year. I really think the scientific qualities of Minnesota Medicine are above reproach, nevertheless I think some member of the Editorial Committee should be here tonight to listen to this resolution because it certainly should be done.

"As I said before, I wish I knew some way whereby teeth could be put into the resolution so they would devote more space to economics. The members of the Association are interested in economics, and the more they can hear about it and the more they can read about it, the more good they will get out of it."

The only further comment was by a member of the Publication Committee who said:

"Without putting further teeth into the matter, I think I can promise that more attention will be paid to the matter of economics"

In pregnancy PROTECT THE TEETH

Obstetricians are familiar with the great amount of dental pathology occurring during pregnancy.

But of greater importance is the fact that with proper care the majority of these dental conditions can be as oided.

Among the causes of dental caries during pregnancy, acidity of the saliva and improper care of the teeth have been mentioned (1-2).

Neutralization of an acid saliva can be brought about quickly and conveniently by means of either Phillips' Milk of Magnesia or Phillips' Milk of Magnesia Tablets. The latter disintegrate readily on the tongue, and each tablet neutralizes as much acid as do three teaspoonfuls of saturated sodium bicarbonate solution

If an alkaline dentifrice is desired, we suggest Phillips' Dental Magnesia.

PHILLIP'S MILK OF MAGNESIA

Prepared only by The Chas. H Phil Chemical Co, New York, N. Y.

So much depends on his mother's diet during pregnancy and lactation

T NO TIME is the need for a protective diet so great as during prognancy and lactation. All elements required for the child's developing body must come from the mother's food-or from her own body.

Cocomalt has well proved its value during these two grods of special stress For not only does it subperiods of special stress stantially increase the calorie intako; it provides extra proteins, carbohydrates, mineral nutrients (calcium and phosphorus) and vitamins. Prepared according to label directions, Cocomalt adds 70% more food energy to milk.

Rich in Vitnmin D

Highly important to both mother and child is the rich Vitamin D content of this delicious chocolate flavor milk drink. Cocomali contains not less than 30 Steenbook (300 ADMA) units of Vitamin D per ounce (under license by Wisconsin University Alumni Research Foundation)

Cocomalt comes in powder form, at grocery and drug stores in %-lb and 1-lb vacuum sealed cans. Also in 5 lb cans for hospital use, at a

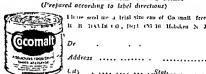

special price Free to Physiciaus

We will be glad to send you a trial size can of Cocomalt. Just mail coupon R B Hoboken, N. J.

American Med-scal Association

DELICIOUS HOT OR COLD

ocomalt is a scientific food concentrate of sucro e skim milk selected goods barley mail extract flavoring and added Vitamin D ADDS 70% MORE FOOD-ENERGY TO MILK

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1.50; three cents each for additional words.

Doctor retiring because of ill health, will sacrifice residence and practice. House brick, semi-detached, with garage. 8 rooms, all improvements, in exclusive community. 10 miles from 42nd St. Old established practice. Price \$12,500. Attractive terms to reliable party. Address Box 28, c/o N. Y. State Journal of Medicine.

COCOMALT

The doctor who says, "drink plenty of milk" can be reasonably sure of his patient's cooperation if he recommends Cocomalt. For even those who heartily dislike milk find Cocomalt a delicious and palatable drink.

Futhermore, prepared in accordance with the simple directions on the label, Cocomalt adds 70% more caloric value to milk. Thus every cup or glass a patient drinks is equal in food-energy value to almost two glasses of milk alone.

Cocomalt mixed with milk is especially valuable in pregnancy and lactation, for it is rich in vitamin D. A glass of Cocomalt, properly prepared, is equivalent to vitamin D content to two-thirds of a teaspoonful of good cod-liver oil. Cocomalt is licensed by the Wisconsin University Alumni Research Foundation under the Steenbock patent. It is accepted by the Committee on Foods of The American Medical Association.—Adv.

WHOOPING COUGH

Elixir Bromaurate (Elixir Gold Tribromide) is being used extensively in the treatment of whooping cough. Due to the definite sedative, antispasmodic and antibacterial action of Elixir Bromaurate, its scope of usefulness has been widened to include other spasmodic coughs as well as the cough of pulmonary tuberculosis. It has also been found valuable in bronchial asthma, chorea, migraine, and petit mal.—Adv.

APPARENT CURES OF PAPILLARY CARCINOMATA OF THE URINARY BLADDER

By JULIUS J VALENTINE, MD, AND JOHN W ROGERS, MD, NEW YORK, N Y

From the New York Polyclinic Medical School and Hospital Presented in connection with the Tifth Annual Graduite Fortnight of the New York Academy of Medicine October 20 1932

ESPITE the bulliant advances we have en joyed in the field of urology and the ever-increasing armamentarium for diagnosis with refinements in surgical technique and treat ment, unfortunately we must confess that comparatively little satisfactory progress has recently been made in the management of bladder malignancy

The difficulties one may encounter in the treatment of malignant bladder tumors whether by excision, fulguration, radiation, or deep 1-ray

therapy, are well known

While we can present nothing new at this con ference, we should like to discuss a series of cases that have been followed through to their termina tion or up to the present time, a small number of which have apparently been cured. In judging cures, or apparent cures, in carcinomata of the bladder, certainly the patient must be clinically free from symptoms or metastases and evsto scopically free from tumor for a long period of time The frequency with which recurrences of the growth or implants occur, even after the bladder has appeared clean for many months has often been observed. Therefore it is of the greatest importance to insist upon making occasional cystoscopie observations even after a cure has apparently been effected

Our discussion will be limited to a group of forty-three cases of papillary carcinomata collected from private and hospital practice during the past few years. We may classify them as

follows

4 Number of cases treated by cystoscopic full guration alone 9 Apparently cured 5 Improved 1 Died 3

B Number of cases treated by cystotomy with fulguration 8 Improved 3 Unimproved 1 Died 4

C Number of cases treated by cystotomy ful guration and radium 15 Cured 1 Improved 1 Unimproved 2 Died 9 Result unknown . 2

D Number of cases too advanced for any form of treatment 11 Died 11

We are therefore able to report only six ap-

parent cures out of the forty-three cases. In nearly every one of these, the tumor was seen comparatively early, was of small size and of low grade malignancy. The only small tumors which we have seen that were not at least arrested following thorough fulguration were evidently not primary in the bladder. These, we believe, were extensions from adjacent organs and were all highly malignant.

The following case is of interest because of the difficulties encountered in its management, the length of time in which the patient was under active treatment and particularly because our efforts were rewarded with an apparent cure

M L, white female, aged 57 years, was first seen on October 9, 1923, presenting symptoms of

hematuria and marked dysurin

The onset of the present illness occurred about three months previously with a sense of obstructed urmation, discomfort in the suprapuble region, urgent urmation and intermittent hematuria listing three or four days at a time. These symptoms had been increasing in intensity and she had lost nimeteen pounds in weight since their onset.

Cystoscopy at this time revealed a bleeding papillary tumor the size of a twenty-five cent piece above and lateral to the right uretral ortice, with several smaller papillary growths on the trigone Biopsy specimen papillary epithe

homa (Dr Douglas Symmer)

On November 22, 1923, a suprapubic cystotomy was performed and the tumors destroyed with actual cautery after which fourteen glass seeds containing a total of 630 millecuries of radium emanation were planted into and around the base of the larger tumor The bladder was drained by a suprapubic tube Specimens of tumor tissue obtained at operation were diagnose l by Dr J R Losee as papillary carcinoma On December 7, 1923, two applicators, each containing 508 millecuries of radium were applied through the suprapubic wound to the approximate location of the larger growth and left in situ for five hours The suprapuble wound healed and the patient left the hospital on January 12, 1924 The urmations were still fairly frequent, accompanied by some prin and discomfort

For the next six months the patient complained of considerable dysuria, but cystoscopy on several occasions failed to reveal evidences of further growth. However, there was a large amount of slough seen at each examination which was evidently causing her pain. There was no hematuria.

After passing one small phosphatic calculus spontaneously early in May, 1924, another one, impacted in the urethra, was removed through the urethroscope about two weeks later. At this time the bladder walls were beefy red and the entire sloughing area in the bladder was found to be covered with a heavy phosphatic deposit which repeated washings and cystoscopic instrumentation failed to remove.

Her suffering continued to intolerance and because of her failing health a second suprapubic cystotomy was advised. Operation on May 15, 1924: sloughing areas cleaned and coagulated using Wyeth's endotherm current. After a stormy convalescence the patient left the hospital on July 1, 1924. Cystoscopies on August 17th and November 21, 1924, showed no tumor, very small areas of slough and bladder mucosa returning to normal. General health improving and urinary disturbance becoming less marked.

Throughout 1925 and 1926 occasional cystoscopic observations showed no abnormality except the small areas of slough which gradually disappeared. Cystoscopic examinations in February

and June, 1927, were entirely negative.

After not reporting for two years, the patient returned in February, 1929. General health excellent. Gained thirty pounds. Only symptom occasional painless frequency of urination. Cystoscopy revealed a very small papillomatous tumor the size of a green pea on the vault of the bladder. A specimen was removed for examination and the tumor destroyed by fulguration. The biopsy report by Dr. Aaron Price was: epithelial papilloma, potentially malignant.

During the years 1929 and 1930 cystoscopic examinations every six months were entirely negative, although in November, 1930, a small wart-like growth about the size of a match head was seen and destroyed by fulguration.

Further observations for the past two years have been entirely negative and on October 19, 1932, the date of her last visit, she was found to be enjoying perfect health, had no urological symptoms and cystoscopic observation again failed to reveal any abnormality.

Inflammatory lesions of the bladder may sometimes be mistaken for true neoplasm even by experienced observers. Joelson and Lower reported three such cases in 1927 and mentioned a number of others previously recorded.

The pathological report often assumes much more importance later on in the management of the case than is realized when the chance to ob-

tain a good specimen first presents itself. A suitable biopsy specimen should be removed at the earliest opportunity. This tissue should ideally come from well within the substance of the growth. The pedicle or base is not always visible and superficial bits of tissue are often unsatisfactory for positive diagnosis. We have several cases which demonstrate the errors which may be made by sending unsatisfactory biopsy specimens to the laboratory for diagnosis.

Case L. W. C.: a biopsy specimen removed five days after one previously reported as benign,

proved to be malignant.

Case Number 4111: biopsy report in 1924: papillary carcinoma of the bladder. Tumor fulgurated and base implanted with radium. Seven years later the patient returned with what was clinically and cystoscopically an inoperable carcinoma involving the entire trigone and bladder neck. Despite these findings an unsatisfactory biopsy specimen was reported as benign papilloma.

We believe that the very evident error in the pathological findings of these cases was probably not the fault of the pathologist, but was due to the fact that no malignant tissue was included in the specimen. On the other hand we have three cases (A. C. L., S. S., 8362) in which, over a considerable period of time, a benign papilloma evidently changed to a malignant one. We base this statement upon the fact that when these cases were first studied, biopsy specimens were reported as benign and after several years the tumors proved definitely to be malignant.

In one case (S. S.), we noted a very marked change in the size of the tumor mass following the removal of the biopsy specimen, at which time only superficial coagulation was done to control bleeding. A tumor, which at first examination was about the size of a lime, apparently hard and with a thick short pedicle, in one month following the coagulation, proved to be a small finely fimbriated papillary tumor with a thin This change we feel was due to the difference in the vascular supply brought about by the passage of the current causing destruction of the blood clot within the growth and shrinking of the tumor mass. We believe this illustration important in that the shrinkage which may take place in the highly vascular type of tumor following coagulation, might make a difference in the mode of attack, whether cystoscopically or suprapubically, since we usually destroy these tumors by cystoscopic fulguration unless they are too large or inaccessible.

Regarding the management of carcinomata of the bladder, we believe that one should certainly have no "hard and fast" rule in the treatment

of choice.

Opening of the bladder suprapubically with wide excision of the tumor is our method of choice where the location of the tumor offers itself to such treatment and where it is thought that all of the cancer tissue may be removed. In our experience these cases are fairly rare.

Fulguration with coagulation through the eystoscope has given us the best results in the smaller tumors and where the patient is tolerant to cystoscopic treatment. The following is our only

example of an apparent cure in a Grade II papillary carcinoma:

E. C., white fcmale, agcd 80 years, first examined in November, 1929. Cystoscopy revealed a papillomatous tumor three-quarters of an inch in diameter, pedunculated, on floor behind sphineter. Biopsy report: carcinoma, Grade II (Dr. Aaron Price). A urethral caruncle was removed and the bladder tumor fulgurated one month later. Cystoscopy in March, 1930, showed no evidence of recurrence. Report by Dr. F. Y. in September, 1932, "arthritic condition, but urologically negative."

The following two cases represent, we believe, what is usually to be expected in the small bladder tumor of Grade I malignaucy when carefully and persistently treated by cystoscopic fulguration.

J. N., white female, aged 63 years, first seen February 10, 1931. Hematuria for one year. High blood sugar. Cystoscopy showed two small papillary growths near the right ureteral orifice. Biopsy: papillary carcinoma Grade I (Dr. Aaron Price). Fulgurated on February 25, 1931, and on March 18, 1931. Observation cystoscopies on April 29 and May 20, 1931, were essentially negative. On October 14th, 1931, several small buds were fulgurated in the area of the original tumors. Cystoscopy on September 7, 1932, showed no evidence of recurrence.

L. K., white female, agcd 38 years, first seen April 23, 1931, complaining of intermittent, painless hematuria for six months. A papillary cystic tumor the size of a grape was seen near the right ureteral orifice. Biopsy: papillary carcinoma Grade I (Dr. Aaron Price). Tumor fulgurated at this time and again on April 28 and June 10th. On June 30 cystoscopy showed the tumor mass to have completely disappeared, but a few cystic bodies were fulgurated. The area of the tumor base was found to be slightly elevated and to bleed casily, on July 15, 1931, and was again fulgurated. Examinations at monthly intervals thereafter showed the condition to be steadily improving and on January 22, 1932, cystoscopy

was entirely negative. Examinations since that time have also been negative, the last examination being on September 16, 1932.

Our experience with radium has not been en-We find that in small low grade malignancy, the results are not appreciably bettered and its possible usefulness is outweighed by the occasional distressing results such as pain, rapid metastasis or extension of the tumor. We have seen no cures or apparent cures, in large bladder tumors of high malignancy, whether radium was used or not. We still use radium occasionally in cases requiring suprapubic drainage because of hemorrlage, painful urination or bladder neck obstruction, but it is usually employed to satisfy the patient or others, or to give the patient "the benefit of the doubt." We are in accord with those who do not consider radium more efficient than coagulation alone to control bleeding tumors. Personally, we feel that the majority of bleeding tumors can be controlled by fulguration cystoscopically; and when not, certainly can when used in an open operation. Pain is often intense after the use of radium and the patient, or his family, may seriously and with some instification, question this mode of treat-The suffering that we have observed at times following the implantation of radium has certainly dampened our early enthusiasm for its

CONCLUSIONS

1. The diagnosis made by the pathologist is often inaccurate because of the unsatisfactory specimen submitted by the operator.

2. Despite the importance of biopsy specimens, experience will enable the cystoscopist to diagnose malignancy from the cystoscopic appearance of

the tumor in the majority of cases.

Apparent cures of small low grade carcinomata of the bladder may result from thorough

fulguration alone.

4. Cystoscopic fulguration in tolerant bladders rather than suprapubic approach with fulguration is preferable if the tumor is cystoscopically accessible and not too large.

Resection of the bladder with wide excision of the tumor area may be done in a limited num-

ber of cases with success.

The use of radium has not, in our experience, been of definite value.

NOISE DEAFNESS IN INDUSTRY AND ENVIRONMENT (Occupational Deafness)

By J. COLEMAN SCAL, M.D., NEW YORK, N. Y.

MPAJRMENT or loss of hearing is a catastrophe for any individual as it not only scparates him from contact with his fellow man by imparting the feeling of inferiority

and helplessness but evidently ends his capacity for earning a livelihood.

Deafness resulting from noisy machines has heretofore been given little attention. In a

report published by the New York State Department of Labor, September, 1930, on "The Effect of Noise on Hearing of Industrial Workers," tests made in groups of one thousand workers definitely indicated that temporary or permanent impairment of hearing are produced by constant exposure to certain noises and vibrations. These noises and vibrations can be measured accurately at any given place by a specially equipped audiometer. Beck established a standard measure of intensity of sound. He proves that very noisy occupations cause deafness and that the deafness advances in time and severity in direct proportion to the intensity of the noise.

There are three types of deafness. The first is catarrhal deafness which involves the middle ear and affects the air conducting apparatus. The second is nerve deafness and involves the inner ear and also affects the auditory nerve. The third, which is known as otosclerosis or progressive deafness, is a hopeless condition and cannot be prevented, arrested or alleviated.

According to Dr. Ritchie Rodger sound is analyzed in the cochlea. Occupational deafness is characterized by increased diminution in hearing accompanied by tinnitus due to excessive irritation of the cochlear branch of the eighth nerve.

The amount of impaired hearing present in a given case is dependent upon the intensity as well as the duration of the noise. Where a single loud noise occurs unexpectedly and deafness follows, the condition may be due not only to a ruptured drum, but also to the damage inflicted on the endings of the auditory nerve in the cochlea. The loss of hearing is more marked in that part of the cochlea corresponding in pitch to the sound to which the individual has been exposed. Where deafness results from steady, moderate occupational noise or environment, it is usually of such insidious onset that it is practically unrecognizable except by an otological examination. In fact it is well known that boilermakers or riveters hear well during the noise of their work, due to a stimulation of the auditory nerve, yet on examination their bone conduction may be reduced to one-third.

In these cases audiometer examinations show the high tones are the first to be impaired. If the noise is continued the process finally affects the auditory perception for lower tones.

Extreme noises such as looms, machinery, riveting, tool sharpening machines, trunk and boiler making, etc. are not the only cause for deafness. Low grade noises like the continuous noise of traffic such as autos, busses, engines, telephone and typewriters are likewise capable

of producing deafness. Such cases are readily discovered by examining middle aged people residing and working in large cities. They are usually found to be partially deaf. A newer form of progressive noise deafness is now appearing in aviators, due to the constant roar of their high powered motors. Rapid descents may rupture the drum due to sudden unequal pressure exerted against both sides of the drum. Testers, mechanics, and aeroplane observers exposed for short daily periods over a long time to extreme noises of their motors or exhaust may become temporarily deaf.

Locomotive engineers and stokers eventually become deaf although the noise of the locomotive is below the harmful tone. This is due to the continuous shaking and straining of ears and sudden changes in air currents as well as the constant presence of nasopharyngeal irritation in such individuals. Only those with normal ears should be employed in such positions, since the presence of a slight impairment of hearing soon becomes aggravated.

The mechanism of auditory injury by steady noise is due to the fatigue of the numerous fine nerve endings in the cochlea which receive the vibrations of sound. Continued fatigue ends in their being irritated and damaged by a degenerative process with resulting loss of hearing acuity. The accompanying head noises, according to McCoy, are due to the swelling of these numerous nerve cells so that they produce the same sensation as it there were a continuous sound vibration against them. Another explanation of noise deafness is that the symptoms can be accounted for by a disturbance in the circulation of the middle and internal ear, which causes a transudation or extravasation of blood into the tympanum or labyrinth which sooner or later results in tympanic deafness.

Telephone Noise Deafness

The proper and ordinary use of the telephone has no effect on the auditory apparatus whatso-ever. The only danger is to telephone operators whose auditory apparatus may become fatigued through the constant and continuous transmission of sound. This, if continued, finally results in noise deafness with its accompanying vertigo, tinnitus, and other nervous manifestations.

Where sudden or excessive vibrations occur in the telephone receivers, acoustic or sound shock may result. This, however, could occur only when using the telephone in a thunderstorm or where highly charged wires had short circuited the telephone. Even this is now impossible as the fuses used by the Telephone Company eliminate this danger.

To avoid noise deafness in telephone operators, only persons with normal ears should be

employed by the Telephone Company. Symptoms of noise deafness in such employees are always found in those who have had a previous ear condition, especially those who are neurologically inclined.

Where a switchboard is in constant use, the intense crackling sound in changing the keys is thought responsible for disturbance of hearing as well as nervous symptoms often experienced by

such operators.

Another occupational deafness frequently met is due to the toxic effects of individuals coming in contact with poisonous materials daily. The hearing is affected by the intoxication of the entire system, involving the auditory mechanism as well. Occupations that necessitate the constant use of lead, arsenic, sulphur, phosphorus, or other noxious gases and vapors are occupations that can be considered accountable for toxic occupational deafness.

Examinations and Tests

The human ear has a normal hearing range of about fifty to seventy-five feet in ordinary conversation and about thirty-six to forty-eight inches for the ordinary watch. Tuning fork vibrations are heard throughout the range from sixteen to twenty-two thousand vibratious in each second.

When testing hearing we should immediately ascertain whether the receiving or transmitting apparatus is involved. The receiving apparatus consists of the internal ear, the labyrinth and the cochlea, which, after receiving vibrations, conducts the sensation to the brain. The transmitting apparatus consists of the ear lobe, the external canal, the drum, and the ossicles which are so arranged as to catch and transmit the vibrations of the air to the receiving apparatus.

Diminished bonc conduction is a sign of nerve deafness. In conductive deafness, bone conduction is increased. The Schwabach's test is of diagnostic value here, since if we find the duration of the bone conduction lengthened, we conclude that there is obstruction to sound perception. While if we find the perception period shortened, we know that there is involvement of the auditory nerve.

Rinne's test depends on the fact that a normal individual hears better by air than by bone conduction. If the sound conduction apparatus is involved the vibration of a tuning fork is heard longer over bone conduction. This is called a negative Rinne.

The best test for nerve deafness in affections of the ear attributed to trades is the finding of diminished bone conduction, Rinne's test being positive. A normal functioning ear gives bone conduction half as long as air conduction, while in conductive deafness bone conduction may be increased.

Prognosis

The prognosis in noise deafness depends upon whether the labyrinth has been involved or not. Noises have a definite physiological effect upon the auditory apparatus, especially in the production of fatigue. Those who work on presses or looms are found mostly to have nerve deafness, since such work is subjected to the greatest amount of noise. The progressive deafness increases proportionally with age. In aged individuals the loss of acuity for higher tones should be considered with advancing age, especially those affected with arteriosclerosis, hypertension or cardiac disease.

Where the dram has been ruptured after an explosion, it usually heals spontaneously. If suppuration follows, the mallcous may be bound down to the internal wall of the middle ear by adhesions. In many cases, the concussion passes off with only slight damage to hearing, although timultus and vertigo may persist for a long time. In such cases, nerve deafness frequently follows.

Treatment and Prevention

Eliminations of floor vibrations could be accomplished by providing rubber soles for workers in noisy occupations. Silencers should be put on all exhausts. Welding should be substituted for riveting. Noisy machines should never be congregated but separated in large airy rooms. There should be Otological examination of all applicants for work at noisy occupations and elimination of those found with impaired hearing, as well as of those having a familial history of deafness. Where cotton plugs are used to stop up the ears they should be considered worthless unless the plugs are first smeared with vaseline or wax. In cases where deafness is progressive the person should be transferred to another department where less noise exists.

Once progressive deafuess has set in treatment is usually hopeless. The disturbed hearing will change into progressive deafuess and will continue so in spite of treatment or changing of occupation or environment.

Conclusions

Hearing once damaged can seldom be improved or restored. Unless proper action is taken noises will continue extracting their toll of deafness, despite the present trend to eliminate them. This is seen today in the advertising of noiseless typewriters, the substitution of riveting for electric welding and the installation of silencers and mufflers for automobiles, gas engines and guns.

Oncoming deafness due to occupational noise gives no warming whatsoever, except when the condition is accompanied by head noises. Examination and treatment must be given when the hearing first begins to drop since only then can

we prevent a permanent loss of hearing. Industries that make people deaf should employ deaf

people from the start.

In arriving at the amount of loss of hearing in an individual case we should keep in mind that where large groups of normal cases were functionally tested hearing defects were found in the majority of cases. This was attributed to the common affections of the nose and throat so prevalent in city dwellers.

Railroad companies, to protect the safety of the traveling public, should have each applicant examined otologically before employing him. They should continue to examine him periodically at fixed intervals, since many disturbances of hearing occur during time of service.

MIGRAINE.—A SYMPTOM OF FOCAL BRAIN EDEMA

By FOSTER KENNEDY, M.D., NEW YORK, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, on April 4, 1933.

hoT has been customary to group together certain acute paroxysmal disorders, asthma. urticaria, migraine, epilepsy, which often occur as a frequent event in certain neuropathic stocks.

Clearly enough the events which each of these names would cover are of the general nature of symptoms rather than of discreet and clearly defined diseases: they represent "reactions to stimuli" and are secondary complexes

rather than primary disorders.

Of 261 families with migraine, Ball found 60 subject to asthma, and 10 with epilepsy. I have been able to report epilepsy and urticaria appearing together as a result of milk poisoning, and together disappearing with the removal of the noxious stimulus; in like manner dermographia often synchronizes with migraine attacks of undetermined cause. It would be entirely misleading; however, to postulate a single constant precipitating factor in migraine. I believe that some of these cases arise from an anaphylactic basis, and my thought quite definitely tends to the notion that this basis will broaden with increased knowledge of the biochemical variants of Three aspects of migraine call for attention and in the first two, knowledge is still speculative in that no anatomical data are obtainable during a paroxysm.

First—the nature of the provoking agent, materies morbi; second—the nature of the response in pathologic-anatomical morbid terms; third the nature of the signs and

symptoms produced.

The last is known well to us all and to the many thousands who suffer from the disease. It would be idle to expatiate on the phenomena of this condition, but it would be well to remember that they are not confined simply to localized periodic severe headache lasting several hours terminating in nausea. The most characteristic attacks are associated with events typical of focal cerebro-meningeal irritation or transient injury. The scintillations are on all fours with the phenomena produced by an occipital lobe irritant and in my experience these crude visual discharges are appreciated in the visual field away from the headache. At times such events are followed by hemianopic defect in the affected field, and may be associated at the time with alexia, or a severe reduction in the educated ability to understand written symbols. Numbness and tingling of the contra-lateral hand and face, rarely of the leg, may be experienced and in such cases a transient motor aphasia is not un-Of course, ophthalmoplegic migraine will come to mind in this regard. Here, the paralysis of the extrinsic eye muscles or of the levator muscle of the eyelid may appear in an hour or two, and may persist for only a few hours. On the other hand this local paralysis may pass off so slowly as to be still apparent several weeks, or occasionally two or three months, later. In our Neurological Wards at Bellevue Hospital today is a woman subject to severe irregularly recurrent right temporal headache, associated with partial or, rarely, complete, 3rd, 4th, and 6th nerve palsy on the right side, together with proptosis of the right eye. Now, such events are clearly of the nature of organic palsies, they are in no sense acutely temporary deteriorations on some vaguely functional character, they have the appearance of coming from a rapid attack on or rapid compression of nerve tissuc with more or less slow recovery of the function impaired thereby.

These considerations of the symptomalogy of the disease lead us to some notions regarding the morbid process at work. At this point we must pass somewhat to theory, for as long as we are ignorant of the abnormal tissue changes produced, speculative pathology must stand in the place of knowledge. Hughlings Jackson has said truly that "the use of hypotheses is the method of science. To suppose that we can make discoveries by the Baconian method is a delusion. A hypothesis or a supposition is not a conclusion, it is only a starting point for methodical observation and experiment, the endeavor being not only to prove it, but to disprove it." The analogy of urticaria and migraine gives one to think in terms of an analogous pathological process in the two diseases. Such a skin process translated to the intracranial cavity would make us visualize localized areas of edema involving chiefly the meninges and especially their foldings and angulated reflexions and less severely, the brain tissue itself. Such localized swellings could form rapidly; their implication of the meninges would cause headache in that these membranes are agonizingly sensitive to stretching. This is especially true of the meningeal areas around the blood vessels which would naturally be the source of the out poured fluid. This discrete fluid mass might irritate contiguous brain areas, the calcarine lobes producing crude visual discharges and by greater incidence field defects, aphasias, and disturbance of visual memory for words. Such fluid swellings in the meningeal folds at the sphenoidal fissure would impinge upon and maybe dysfunctionate the neighboring cranial nerves, and in a space so narrowly enclosed this incidence might be such as to prevent recovery of function in these nerves for weeks after all fluid had been absorbed or drained away. Indeed as far as a morbid process is concerned this theory would seem to fit the known clinical facts, and is the more engaging if the analogy be pursued into associated symptom complexes: that edema of the skin may appear as urticaria; edema of the brain, as in alcoholic or uramic poisoning, as fits; and that edema of the cerebral meninges with especial pressure in the meningeal crevices may produce the localized headache and the local cerebral symptoms of migraine.

The problem grows more obscure when we proceed to the consideration of our first aspect of this disease: the nature of the noxious agent.

Gowers long ago recorded the fact that certain migrainous persons could produce an attack by eating foods by which they would be poisoned—and this was appreciated long before we were aware of even so little as we now know of allergic happenings.

We begin to realize that inate sensitiveness may account for more medical phenomena than we have dreamed of in our philosophies, and Cook has shown that many novious products absorbed from the intestinal tract fail to give rise to skin reactions.

It would therefore seem valuable to practise observation and pursue experiment in migraine along allergic lines; already we have found in the ease of migraine described above with a sphenoidal fissure syndrome that recovery from symptoms and maintenance of health result from an "elimination" diet, and immediate return of pain and local palsies was effected by resumption of the offending protein.

Riley has of late reported most interesting results in his research in migraine. He found a deficiency in Theelin, the ovarian follicular hormone in his patients and further that Prolan A could be recovered from the urine of migrainous and non-pregnant women.

Riley was able to produce a migrainous seizure by the hypodermic injection of 2 c.c.s. of Prolan A and B, but Brock, working in our Clinic in Bellevue Hospital, was unable to secure any result by the use of half that amount.

Undoubtedly, persons afflicted with migraine often suffer gonadal abnormality, hyperthyroidism and endocrine disturbance by thymic persistence, all related possibly to disordered pituitary function. However, such disordered function does not necessarily emanate from primary hypophysical or other endocrine pathology, but might, I submit, emerge as a secondary or neighborhood pituitary sign, even resulting thereby in the abnormal hormonal urinary findings: it is not impossible that a localized edema of the basal meninges might give rise to such endocrine errors as appear in this (disease) symptom But this drum must not be too much beaten upon-hormone error may well often be basic, but certainty in this matter must be for the future.

A word in conclusion regarding the results of certain drugs in the experimental examination of migraine as carried out by Dr. Brock in our Department at Bellevue Hospital. Here it was found that ergotamine tartrate an antisympathetic in action and known best by its trade name of "gynergen" in pills of gr. 1/100 each would cut short a migrainous paroxysm but with the unfortunate complication of occasional induction of vomiting. It has been found that daily or alternate daily injections of theelin prolonged the intervals between attacks, and no paroxysm could be produced by over dosage with insulin nor by hyperventilation nor the use of 95% oxygen and 5% carbon dioxide inhalations.

However, when we've considered the small sum of our knowledge of the treatment of the acute seizures we retreat on the fact that morphine and its derivatives give aid when all else fails, and in severe cases must be employed with due regard to the personality of the patient. In fine, the solutions of epilepsy, migraine and other paroxysmal disorders, including, I believe, many of the psychoses, are behind doors the locks of which we pick at, but which some day will be opened by the key of biochemistry when it has reached a larger stature than it has at present attained.

DISCUSSION

Dr. Henry Alsop Riley, New York City: Dr. Kennedy brings before our attention the essential problem connected with the causation of the migrainous seizure. This question has absorbed a great deal of my attention for the last two or three years.

I quite agree with Dr. Kennedy when he states that migraine is a symptom-complex and that many causative factors seem to be able to evoke the essential response, the migrainous seizure, from the bodily organization. It is a matter of common knowledge that a large group of patients presents a type of migraine which may be considered to be the symptomatic form. These patients often show definite deviations from the normal in connection with refractive errors of the eyes, disease of the accessory sinuses of the nose, dietetic idiosyncrasies and other manifestations of a constitution susceptible to allergic influences. It is also well known that patients suffering from brain tumors, pituitary neoplasms, chronic hydrocephalus and other disorders of miscellaneous character may present what appear to be typical migrainous attacks. There must, therefore, be a number of etiological factors active in the excitation or activation of the migrainous seizure. Whether there is one final unitary channel through which act the essential processes which result in the actual attack is uncertain at the present time but it is the object of earnest and conscientious investigation in many neurological and general medical centers.

I agree with Dr. Kennedy that the vasomotor theory is one of the most attractive of the hypotheses proposed for the explanation of this syndrome. On the basis of vascular cramp almost all of the symptoms of migraine may be very satisfactorily explained, but except for some restricted collateral evidence we have no direct proof that angiospasm is the cause for migraine. As Dr. Kennedy has quoted, Hughlings Jackson has given respectability to "supposition" as a creditable basis for scientific investigation and it often serves as a very useful point of departure. What is behind and at the root of the vascular spasm still remains uncertain. Not long ago a physician from the South wrote to me enclosing a sketch made of his own fundus during a migrainous seizure. Comparison with the vessels of the fundus during the attack and in the interval between attacks showed a very definite diminution in the calibre of the arteries and a general blanching of the retina in the eye on the side of the head in which the headache occurred.

Not long ago a child came into the Vanderbilt Clinic with the statement that she had suffered three days previously from a migrainous seizure and without our being informed, four or five of us looked at the fundus and all of us without mistake picked the side of the head in which the headache occurred by the appearance of the fundus. The nerve head was quite obscured and the radial markings over the edge of the disc were much more prominent than on the other side.

I agree with Dr. Kennedy in separating the ophthalmoplegic type of migraine from the simple and ophthalmic types. I quite agree with him in his statement that symptoms of ophthalmoplegic migraine represent what would appear to be the effects of definite pressure neuritis. In almost every characteristic, ophthalmoplegic migraine differs from the other types. There is a much less definite hereditary element, it makes its appearance in an earlier age epoch, it is much more stereotyped and unvarying in its manifestations, it is less regular in the time of recurrence and the sequelae are much more enduring and more inclined to become permanent. In addition, what pathological evidence there is uniformly presents the presence of organic alterations in the form of neoplasms, inflammations, meningeal thickenings, vascular dilatations and other deviations from the normal in the oculomotor nerves themselves or in their immediate vicinity. All of the autopsy reports which I could find in the literature showed the presence of actual pathological changes in patients who had suffered from ophthalmoplegic migraine.

Dr. Kennedy has been kind enough to refer to the work which Dr. Brickner, Dr. Kurzrock and I have been carrying on at the College of Physicians and Surgeons and at the New York Neurological Institute on the relation between the migrainous seizure and the endocrine glands, particularly the gonad and the hypophysis. The connection has been emphasized for many years and we therefore

decided to investigate the excretion of the sex hormones in the urine of patients suffering from migrainous attacks. The relationship of the ovary has, of course, been emphasized for centuries, principally because of the relation between the migrainons seizure and menstruation and the fact that migraine is usually limited to the menstrual life in females, failing to appear during the ecssation of ovarian functions such as that occasioned by pregnancy, lactation and the spontaneous or operative menopause. The hypophysis has been implicated principally on account of its position in relation with many of the structures whose involvement would explain many of the symptoms of migraine. The relation of the hypophysis to the migrainous seizure has also been emphasized on clinical grounds. The hormones which we have investigated are prolan secreted by the hypophysis and theclin produced by the ovary. Prolan from the hypophysis consists of two prolans, A and B, the former being active in the production of the ovarian follicle and the latter bringing about the luteinization of the folliele after it has ruptured and the ovum has been extruded. Theelin is active principally in the production of the phenomena of menstruation. The group of patients studied consisted almost entirely of women within the menstruating age. There were three who were past the menopause, either spontaneously or artificially. were all sufferers from simple migraine. There were two males in the group. In studying them we examined the urine for the presence of hormones over a period of about three weeks during which time all of the patients had one or more headaches and all of those who were menstruating passed through one of their periods. From the study of the excretion of the hormones and the occurrence of the migrainous attacks we conclude:

 While theelin was almost consistently absent from the patients forming the preliminary group in whom only single specimens were examined, the study of the daily urine excretion recorded the occasional presence of the hormone in all but one of the menstruating individuals and in this woman the menopanse was imminent. In one woman who had passed a natural menopause, theelin was absent, as was the case also in another woman in whom the menopause had been induced by operation. In all of those in whom theelin was demonstrated the hormone was absent sporadically and when present the amount of theelin rarely exceeded five rat units per liter. Only exceptionally did the quantity of hormone reach the ten to twenty rat units which is considered the normal amount for women within the menstrual age.

 No demonstrable relationship could be determined between variations in the excretion of theelin and the occurrence of headache.

3. In all of the cases, prolan was excreted. In the two women past the menopause and the one approaching it prolan was present almost daily in large quantities; in the remaining Il cases the hormone was demonstrated intermittently and in varying amounts.

4. In the entire group of patients investigated, twenty-nine individual headaches occurred. Headaches which continued over consecutive days were considered, for purposes of tabulation, as constituting a single attack. In two patients (H. J. and S. M.), the headaches were so continuous as to constitute a status unigrainicus, not being separable into single headaches, and therefore could not be included

in the number (29) given above.

In 20 out of the 29 instances the headache was preceded or accompanied by the appearance of prolan in the urine. In calculating the number of days by which the appearance of prolan antedated the headache the interval was determined by counting from the first day of the appearance of the hormone to the beginning of the headache. In one patient (A. S.) in whom the initial appearance of prolan antedated the headache by an internal of three days-prolan appeared on each of the three consecutive days and disappeared with the oceurrence of the headache. In the patient B. H., on one occasion prolan was demonstrated four days before the headache, but continued to appear in the urine for three of the four days. In another instance in which the headache was preceded by an interval of six days, the prolan continued to occure on each of the six days, failing to appear only on the day of the headache. In four instances the eontinuous exerction of prolan extended through at least a part of the period of the headache. In one patient (C. R.), the prolan appeared for two days, was absent for one day and recurred coincidentally with the occurrence of the headache. The incidence of headache and prolan excretion limited to a single day coincided in only two instances. The interval by which the one antedated the other was, in 7 instances, one day; in 4, two days; in 5, three days; in 1, four days, and in 1, six

In the two patients presenting a status migrainicus, the excretion of prolan was practically uninterrupted. There was, therefore, a continuous relationship between the appearance of prolan and the occurrence of headache. In one patient, a practically continuous prolan excretion occurred over the period of observation, but during this time only three headaches took place. In this patient it was therefore

48" 12 y

impossible to relate the headaches to any par-

ticular day of prolan excretion.

5. In nine of the twenty-nine headaches, no prolan-headache relationship was demonstrated. In seven of the nine headaches, however, the determination of an exact relationship between the appearance of prolan and the occurrence of headache was rendered impossible by the absence of urine specimens. In the remaining two of the nine, the requisite number of specimens was obtained but the headache occurred without the antecedent appearance of prolan.

6. Occasionally, prolan appeared without the subsequent development of headache. Of the three cases showing almost daily prolan excretion, one individual failed to develop a headache on only one day, another was free from headache on only an occasional day, but the third, as stated above, was free from headache the major part of the time of observation. In the remaining eight patients, in whom prolan appeared intermittently, a headache failed to follow the excretion of the hormone only five times.

7. Of the eight menstruating women, seven had attacks with menstruation. No definite difference could be determined in the relationship between menstruation, headache, and the excretion of prolan, from the headache-prolan relationship occurring at other times.

8. Prolan was excreted in association with all menstrual periods, except in the case of E. S., in which the requisite specimens were

not obtained.

9. Nine female patients were injected with 2 cc. of follutein and seven developed an attack of migraine within four to twelve hours. The attack was either mild or severe was always presented the migrainous charac-

teristics which were typical for the individual.

10. Only two men were studied during the period covered by this preliminary investigation. One man had six, and the other had nine headaches. In the patient with six attacks (S. O.), specimens preceding one headache were lost, but all of the other attacks were associated with the excretion of prolan within a period not exceeding three days. In the other male patient (C. W.), with nine headaches, specimens were lost preceding one attack. Of the remaining eight attacks, headache was associated with the excretion of prolan in only four instances; he, therefore, had four headaches without the associated excretion of prolan.

Follutein was administered to patient S. O. twice, the injections being separated by an interval of six days. A typical two-day headache developed following the injection after three days. After the second injection no

headache developed.

The experiments have not yet been controlled by the study of a non-migrainous group over a comparable length of time. This will be one of the next steps in our investigation. I believe that this is the first tangible evidence presented that the migrainous seizure can be definitely related to some perhaps perverted activity of the gonad or the hypophysis. We do not believe that this solves the problem of migraine by any means but we do believe that it presents a very useful point of departure for further investigation and for the treatment of the disorder. Without doubt further reports of this investigation will follow.

The support upon which this investigation has been carried out has been supplied by the Josiah Macy, Jr., Foundation and the Chemi-

cal Foundation.

A STUDY OF FAINTNESS AND SYNCOPE IN ASSOCIATION WITH CARDIOVASCULAR DISEASE*

By LOUIS FAUGERES BISHOP, M.D. AND LOUIS FAUGERES BISHOP, JR., M.D., NEW YORK, N. Y.

NY clinical study of a symptom occurring in cardiovascular disease often becomes a tific investion of one's own personal experience. useful point or in mind that we undertook this and at the root cand syncope are considered here mains uncertain. as being allied symptoms, both from the South wroto cerebral anemia. It is obmade of his own funer of underlying causes of seizure. Comparison of the American Therapeutic 17, 1932.

such frequent symptoms encountered may be

legion.

As our observations in this paper are essentially on ambulatory patients, examples of syncope which might, for example, be due to abundant cerebral hemorrhage are naturally excluded. Also, in recording the history we must, in most cases, rely on the individual description and replies to questions. The great majority of these people were referred or came directly to our office

because they felt that their symptoms were in the main due to disturbances in their circulation. We were particularly interested when these attacks could be traced to these facts. A similar study would be of interest from the standpoint of any branch of internal medicine.

As a basis for this study we reviewed five thousand private historics of cardiac disease. These people had been rather carefully studied and observed. Faintness or syncope was a primary complaint in two hundred seventy-four. It became immediately evident that faintness or syncope, due to cerebral anemia, might be tolerated differently by different individuals from whatever cause. We first decided to determine the incidence of these symptoms with regard to blood pressure.

Arbitrarily, any patient who had a fixed diastolic pressure of 100 or over was considered to be a hypertensive individual, and any adult patient with a systolic pressure of 110 or less was considered to be a hypotensive individual. The occurrence of faintness or syncope in hypotension and hypertension showed that about one-half of those with these symptoms had hypertension and less than ten per cent had hypotension. This was irrespective of other accompanying factors that might be present. Although it is well known that faintness or syncope is frequently associated with either hypotension or hypertension we did not expect so frequent occurrence in hypertension and we rather felt that it would be more frequent in a constitutional state such as hypotension. (Table 1.)

A second common clinical observation is what is usually called the ordinary attack of fainting generally considered to be of vagus origin. Attacks of syncope due to fainting have long interested clinicians. In fact before the introduction of anaesthetics, it was the frequent custom to perform operations in a state of syncope which was induced by laying the patient flat on the ground for a short time and then raising him very suddenly to the upright position.

The opportunity, however, to study the physiology of faintness and syncope is not frequent. We had an opportunity recently to observe a man during an attack of syncope, while he was seated for an electrocardiographic examination. The electrocardiogram revealed that his attack was accompanied by an unusual arrhythmia. This

has been reported by us in a recent publication.²
Starr and Collins who have done work on the physiology of fainting feel that it is due to cerebral anemia.² We were interested to note in their findings that electrocardiograms taken in two of their fainting cases revealed nothing except minor variations in the T wave.

It is apparent that there may or may not be present a disturbance of the cardiac mechanism in a simple fainting attack. Disturbances in cardiac mechanism that may result in faintness or syncope as a symptom can be classified as follows: (This is a modification of a similar classification given by Lewis.*)

Accelerated Heart Action—Simple Tachycardia. Repeated Extrasystoles. Paroxysmal Tachycardia. Auricular Fibrillation. Auricular Flutter. Ventricular Fibrillation.

Retarded Heart Action—Simple Bradycardia. Sino-Auricular Block. Partial Heart Block. Complete Heart Block. Bundle Branch Block.

Thus, either an accelerated or retarded heart action may compromise the blood supply to the brain and cause faintness or syncope.

Electrocardiographic Study:

Of the two hundred seventy-four histories which we reviewed we had taken one or more electrocardiograms on two hundred eighteen. In this analysis it was noted that there was present a wide variety of disturbances of cardiac mechanism, as is shown in Table 2.

As early as 1908 Walter James called attention to an example where recurrent extrasystoles gave an arterial pulse of 36 with heart beats of 72, of the true bigeminal type. None of these extrasystoles reached the wrist and with the slow pulse there was a sensation of sinking and at times an incomplete loss of consciousness. In our study we found numerous examples where extrasystoles were accompanied by these symptoms and it can be considered one of the most important of the Stokes-Adams equivalents.

Faintness and syncope are particularly common in paroxysmal auricular fibrillation and flutter, especially during onset. Many authors have called attention to the difficulty involved, particularly in children, in differentiating attacks of petit mal, with accompanying faintness and syncope from paroxysmal tachycardia. It is almost need-

less to say that an examination of the heart during attacks of unconsciousness should always be made. Willius has called attention to the attacks of cerebral anemia prone to occur in paroxysmal tachycardia, particularly in those examples where the path and origin of the impulse to contraction are distant from its normal site.⁶, ⁷ We should not feel, however, that paroxysmal tachycardia or fibrillation is invariably attended by cerebral anemia.

That ventricular fibrillation is not always the cause of fatal syncope has been recently emphasized by Schwartz⁸ who, in a remarkable case, observed a patient who suffered from sixty-seven seizures of unconsciousness during a period of seven months. Each one of these was associated with periods of ventricular fibrillation. In addition, this patient had a complete heart block. He feels that periods of unconsciousness in patients with complete heart block are associated with transient seizures of ventricular fibrillation far more commonly than has been suspected; also, that a clinical diagnosis of ventricular fibrillation might be suspected if preceding a period of unconsciousness the heart rate had been noted to increase above that of the usual basic rate.

A few years ago at Bellevue Hospital the junior author of this paper observed an example of transient ventricular fibrillation with syncope. The patient died a few days after the electrocardiographic observation of the attack.

Although variations in rhythm such as have

been described above may frequently be the underlying cause of attacks of faintness or syncope, and are relatively common, they are not very often recognized. This is due not only to the labon and expense of frequent examinations as there is also a natural improbability of the expected change of rhythm appearing at the particular time during which the patient's heart is being recorded. It is, therefore, relatively rare to be able to prove that attacks of faintness or syncope are due to a fugitive abnormal rhythm.

The second large groups of disturbances of cardiac mechanism which can result in attacks of faintness or syncope are those grouped under retarded heart action. First, sino-auricular standstill alone, or standstill of the whole heart, usually of vagal origin, may cause these symptoms. Alfred E. Wedd⁹ has recently reported two examples of cardiac syncope with this mechanism.

The term Stokes-Adams syndrome is usually connected with varying degrees of heart block, either the onset of complete heart block or the increase of a pre-existing block. It is quite possible that many of the original cases described by Stokes were attacks of faintness or syncope of an entirely different cardiac mechanism from what we now consider heart block. It is well known, too, that after the onset of a complete heart block attacks of faintness or syncope usually disappear, unless there is present some other influence on the ventricular pacemaker. This influence may be either an increase or a decrease in the ventricular rate, the end result being the same.

Gallavardin¹⁰ has recently called attention to the fact that cardiac pain may be frequently accompanied by vertigenous and syncopal attacks of, sometimes, a very impressive nature.

In a recent analysis of one hundred examples of cardiac pain seen in private practice we found that faintness and syncope complicated cardiac pain from all causes in eight examples.¹¹ These symptoms were more frequent where marked arteriosclerosis was present. In conjunction with this syncope can occur in attacks of coronary thrombosis either with or without pain, usually the result of an extreme state of collapse. We have observed recently an example of this in a physician who had several attacks of syncope, preceded by slight pain, later proving to be coronary thrombosis.

SUMMARY

1. Faintness or syncope is seen by the cardiologist relatively often as a chief complaint.

2. Its frequent occurrence in hypertension is again emphasized. It was not so often found to be associated with hypotension.

3. Disturbances in cardiac mechanism may often be the underlying cause of faintness or syncope.

4. Faintness or syncope may be a symptom of

coronary disease.

ROUTINE MANAGEMENT OF THE GASTROSTOMY PATIENT

By WILLIAM L. WATSON, M.D., NEW YORK, N. Y.

From the Service of Frederic W. Bancroft, M.D., Fifth Avenue Hospital*

TE have employed with satisfactory results the following routine preoperative and post-operative measures in a series of seventcen (17) gastrostomies. Patients for whom a gastrostomy is indicated require careful detailed management if postoperative results are to justify the procedure. Careful attention to detail in the pre-operative preparation of the dehydrated and emaciated patient will reduce to a minimum the element of danger connected with the opera-Possibly no standard operative procedure requires more constant intelligent post-operative care than does a gastrostomy. The purpose of this paper is to outline briefly a satisfactory routine for the care of the patient before and after gastrostomy.

Pre-operative Care

A gastrostomy is usually performed as a palliative measure in patients suffering from cancer of the esophagus. Most of these patients, unless they are edentulous, show an advanced degree of intraoral sepsis. The bacteria responsible for this condition are carried downward by fluids and saliva and maintain a chronic state of inflammation and suppuration in the ulcerated esophageal lesion. This inflammation causes edema and narrowing of the esophageal lumen with a resulting increase in the trauma due to food and peris-This suppuration has the systemic effect of lowering the patient's vitality and the local effect of increasing the growth activity of the carcinoma. When time permits, it is best to clean up the dental condition before operation thus improving the patient's general condition and lessening the danger of post - operative wound infection. washes are used frequently and apparently lessen the "bad taste in the month" complained of by the patients.

Solid foods as a rule will not pass through the obstructed area and, for this reason, the diet is restricted to liquids and semi-solid Small feedings are given frequently and the fluid and caloric intake is carefully checked each day. The main article of diet is milk and this should always be boiled, Coddled eggs, soups, apple sauce, fruit juices, and cooked cereal with eream and sugar make up the bulk of the diet. Lactose, which in general is well tolerated, is added whenever possible.

Due to the patient's age, the low residue diet, and the diminished fluid intake, constipation is usually troublesome. Care must be taken to avoid fecal impaction which may oceur in severe cases. One such complication occurred in this series. We have given a combination of two drains each of milk of magnesia and mineral oil three times a day with satisfactory results. Colonic irrigations may be necessary.

Dehydration and emaciation are always present to some degree. When dehydration is severe fluids are forced by all routes. Hypodermoclyses of normal saline, intravenous saline, and rectal taps are given in an effort to restore the water balance. large amounts of fluid these dehydrated patients absorb is quite remarkable. patient is given two hypodermoelyses of normal saline the day before operation and a third hypodermoclysis on the morning of the operation.

Most of these patients show a diminished hemoglobin due partly to chronic low grade sepsis, partly to the constant oozing of blood from the esophageal lesion, and partly to an unbalanced diet. Transfusions of whole blood greatly improve the patient's preoperative

Operative Technique

The operative procedure carried out in the seventeen cases forming the basis for this report has been previously reported in detail. The method is essentially the same as that described by H. H. Janeway in the Journal of the American Medical Association in 1913. There are, however, several minor modifications as shown in the illustrations.

Combined infiltration and intercostal nerve block anaesthesia with 1% novocaine is used in all cases. General anaesthesia is not neces-

sary and the poor general condition of the patient makes it undesirable. The various steps in the operative procedure appear in figures 1-2-3-4 Care is taken to guard the structures of the abdominal wound against contamination with the stomach contents, as this material is teeming with saproplutes and pus forming organisms from the ulcerated esophageal lesion.

The operative procedure usually takes about forty-five minutes following which the patient is returned to the ward and the head of the bed elevated so that he sits practically upright I feeding of three ounces of water is administered through the gastrostomy tube immediately to clear the tube of blood clots.

Post-Operative Care

Chart No I outlines the daily treatment in the uncomplicated gastrostomy cases for the first twelve days post-operative. At the end of this time the patient is taught to insert his own feeding tube, make up his own feed-

Day of Operation

patient seems able to understand and follow

In this series of seventeen cases there was one post-operative death, a mortality of 5.9% The patient who died after operation had carcinoma of the esophagus and pneumonia with a fever of 103 4 degrees Fahrenheit when seen prior to hospitalization He was unable to take any fluids by mouth due to a complete esophageal obstruction His pneumonia was due, no doubt, to aspiration of fluid which had spilled over from the pyriform sumses into his larynx. Glucose administered intravenously, saline hypodermoclyses, and rectal taps brought about a marked improvement and his On x-ray temperature returned to normal the pulmonary condition seemed less menacing, and, as the patient was most anxious to live as long as possible, we performed a gastrostomy to simplify the feeding problem. His immediate post-operative reaction was satisfactory and the wound healed by primary The sutures were removed on the

Seventh day post-operative

Peptonized milk, ounces 10, q 3 h plus the lactose and add one egg three times a day

Remove sutures

Eighth day post-operative

seventh day and he was up and about the room when, on the ninth day, his temperature suddenly rose to 103 degrees Fahrenheit and he developed chemical and radiographic signs of pneumonia The patient died on the eleventh post-operative day. His abdomen remained soft throughout, and fluids were given through the gastrostomy tube until the Permission for an autopsy was not obtained.

All of the other cases showed marked temporary improvement. The dysphagia decreased in all the carcinoma cases and disappeared entirely in several. One patient found he could eat normally and refused to return to the hospital for observation. One evening four and one-half months after operation while eating a heavy meal of corned beef and cabbage he developed an acute obstruction and died rapidly of aspiration pneumonia and septicemia.

Three patients in this series were in the early stages of their disease as evidenced by their good general condition. Exploratory mediastinotomies were performed on these patients; two of these died post-operatively and one died shortly after leaving the hospital. These were apparently the three most favorable cases in this series and following gastrostomy under average conditions they would have lived for a longer period of time than any of the others. Life expectancy in these cases was shortened by the second operation. One patient had a gastrostomy performed because of mediastinitis caused by a foreign body perforating the upper esophagus posteriorly. Her

Hour of Feeding	Milk	Milk Sugar	Butter (Melted)	Eggs (Raw)
6 A.M	2½ cups or 17 ounces	3 scant tablespoonfuls	1 teaspoonful	1
8 A.M	(8 ounces	tomato juice)		
10 A.M	17 ounces	3 scant tablespoonfuls	1½ teaspoonfuls	2
2 P.M	17 ounces	3 scant tablespoonfuls	1½ teaspoonfuls	1
6 P.M	17 ounces	3 scant tablespoonfuls	1½ teaspoonfuls	1
10 P.M	17 ounces	3 scant tablespoonfuls	1½ teaspoonfuls	2

At 10 A.M. 1 dram (1 teaspoonful) iron and ammonium citrate.

- Insert tube only for feedings.
- 2. Make up each feeding fresh. Heat slightly before
- 3. Take feeding slowly—allow at least 15 minutes for each feeding.
- Rest 15 minutes after each feeding. Clean feeding tube with water after each feeding do not boil.
- 6. Obtain from the Drug Store:
 - 1. One #12 French catheter.
 - 2. Asepto syringe with tip to fit catheter.
 - 3. Large can of lactose (milk sugar).

CHART No. II: Discharge diet and instructions given the patient when he leaves the hospital.

Several patients were relieved of symptoms and returned to their normal occupations. Sixteen wounds healed by primary union and only one became infected and had to be opened down to the anterior layer of fascia. did not, however, delay convalescence appreciably. Occasionally, in the late stages, when the carcinoma patient is coughing constantly and regurgitates frequently and his musculature lacks tone, we encounter some slight leakage about the stoma. The surrounding skin may be protected from the action of gastric juices by the frequent application of a dusting powder of copper as recommended by Cunningham (4). If the goose neck tube is of the diameter recommended and a No. 12 French catheter has been used then leakage even in the late stages is very unusual.

4. Iron and Ammonium Citrate, ounces 8, and take 1 teaspoonful in 10 A.M. feeding.

5. One 8-ounce measuring cup.

7. If constipated, take one ounce of castor oil in the last feeding at night.

Take nothing by mouth except water. This may be taken in small amounts if it does not cause vomiting.

- 9. If stomach distress and nausea follow the feedings, the milk content should be reduced to 12 ounces for 2 or 3 feedings.
- 10. Any unusual symptoms or difficulties should be reported to the hospital.

CHART No. IV.—Summary of the post-operative course of the seventeen (17) gastrostomies used in this series. The diagnosis was carcinoma of the esophagus in fifteen cases; case #11 was carcinoma of the larynx, and case #12 was retropharyngeal and mediastinal abscess. Local anaesthesia was used in all the cases except one in which gas oxygen and ether anaesthesia was used. Primary healing occurred in all the incisions except that of case #4. No leakage of gastric contents occurred in any of the cases.

UNFILTERED X-RAYS AND THE TEN MILLIGRAM FLAT RADIUM ELEMENT APPLICATOR IN DERMATOLOGY. A RESUME OF PERSONAL EXPERIENCE AND OPINION

By GEORGE M. MACKEE, M.D., NEW YORK, N. Y.

Read by invitation before the Section on Dermatology and Syphilology, at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

S a rule, in most vocations and avocations, knowledge and accomplishment advance with each generation. Certainly, this is true of the science and art of medicine of which dermatology is a part. As a result of increased knowledge, together with improved undergraduate and graduate medical instruction, greater facilities and stricter requirements, the modern dermatologist knows more about etiology and therapy than did his predecessors. He is more efficient; his ability and knowledge are much more comprehensive. Formerly he was essentially an "externist"; now he is both "externist" and "internist." He is thoroughly acquainted with the external causes of skin diseases; also with the external management of such affections; and he knows more about the constitutional causes of the dermatoses than do physicians in any other field of medicine. As Highman once said, it is the dermatologist who knows when to be an "externist" and when to be an "internist."

The foregoing paragraph is a preface for the statement that x-rays are now employed somewhat less frequently in dermatology; and it is possible that they will be used still less frequently in the future. Dermatologists whose training has not been comprehensive, are likely to use x-rays indiscriminately. On the whole, however, there is an increasing disposition on the part of dermatologists to employ x-rays only when necessary or when definitely indicated; in other words, with discriminating judgment. This trend is most noticeable among the older dermatologists and is the result of accumulated experience; also among adequately trained young dermatologists who are capable of guidance.

Twenty years ago certain dermatoses were treated with x-rays because there was no other equally efficacious remedy. Since then other methods of treatment have proved equal or superior to x-rays in these particular affections. For instance, warts of various kinds will often

respond more favorably to injections of bismuth or arsenic, or to some other agent than to x-rays. At one time, x-rays constituted the therapeutic method of election for the troublesome plantar wart. Now we know that with amounts that are safe to administer, only about seventy percent can be cured in this manner, while it is possible to cure over ninety percent with properly applied electrosurgery. X-rays are of great value for selected cases of warts and keratoses, but they are by no means always the best or the most certain method.

Radium is still considered the best therapeutic agent for cavernous angiomas of infants. However, in safe doses, it is not always successful. It is not efficacious and it is even contraindicated when the lesion has endured for a number of years. Also, because of the danger of serious injury to the eye, it may be inadvisable to apply radium to the more stubborn lesions when situated on the eyelid. For these and other reasons, excellent judgement is necessary for the selection of the best method of procedure for the particular case. Other methods are scalpel excision, plastic surgery, electrosurgery and injections. In this connection, it should be borne in mind that a cavernous angionia may spontaneously improve or disappear.

It used to be customary to treat a carbuncle with one intensive dose of filtered x-rays followed later by a free incision. In recent years bacteriophage, with and without incision, has given better results.

There was a time when nearly every patient who consulted a dermatologist in this country for the treatment eczema, received x-ray treatment regardless of the clinical characteristics of the eruption. In those days, eczema was diagnosed as such with adjectives to designate cither the location, the stage, or other restricted elinical characteristics. The eczema of that period has been divided into what, for convenience, may be called clinical or etiologic entities. Thus we have eczema seborrheicum, eczema venenatum, eczema hemostaticum, dermatitis infectiosa eczematoides. dermatophytosis, dermatophytide, neurodermatitis, etc. Very often it is possible to recognize the variety and such identification provides a clue not only to the cause, but to the most efficacious treat-There are, of course, many eruptions which possess the characteristics of eczema but which do not fit into any of the types mentioned above. In many instances the cause cannot be ascertained. In some cases the eruption may be due partly or wholly to a bacterial or fungus focus, diabetes, the ingestion of a drug, or other internal and external factors.

The point to be emphasized here is that the modern experienced dermatologist, instead of depending solely upon x-ray treatment attempts to ascertain and remove the cause, and endeavors to

allay distressing subjective symptoms and hasten resolution by means of judicious topical applications combined with general medical measures. This is done not only because it is more scientific, but because often indeed recovery is more rapid. Assume, for example, a case of eczema venenatum due to primrose. X-ray treatment will be of little if any benefit if the cause is not detected and removed. When the cause is removed, the eruption will usually disappear as rapidly without as with x-ray treatment. Another simple example is eczema hemostaticum caused by varicose veins. In most instances, proper support for the circulation and proper topical remedies will do more than ean be accomplished with x-rays alone. Much more interesting and instructive examples could be cited, but they would be too time consuming for this short paper.

At one time many of us thought that x-rays hastened involution of eczematous eruptions regardless of etiology or clinical type. Experience has caused such opinions to be modified. In general, it may be said that three or four weeks are required for a patch of eczema to disappear as a result of x-ray treatment that is safe. If it disappears in a week or two, it is probable that xrays had little if anything to do with the improvement. The same statement holds for the relief of symptoms such as itching, burning and stinging. Quicker results can often be obtained with topical remedies, general medical measures, hospitalization, controlled environment, various injections and other measures according to indications. Furthermore, eczema of various kinds is likely to continue indefinitely or recur repeatedly in spite of x-ray treatment, as long as the cause is operating, or the patient remains sufficiently

In spite of the foregoing statements, Howard Fox's remark, made about twenty years ago, that x-rays constitute the best single remedy for eczema in general, still holds. Not infrequently, it is the only therapeutic method that will afford relief in a few weeks. However, when a permanent cure is affected in about a month, it is probable that the cause has disappeared or the allergic state of the patient has become modified. Theoretically, it is conceivable that x-ray treatment alone may accomplish this in some cases, but in most instances it is probable that the allergin and the allergy have been modified spontaneously or by other methods.

A very long period of time is necessary for the accurate evaluation of a therapcutic method. It often happens that one will obtain a certain result with one series of patients and a different result with another series. Many years ago, in my own work, over a period of about seven years, every case of lichen planus was clinically cured in from three to six weeks with a-rays and so far as I know there were few if any recurrences.

Naturally, I regarded x-rays as almost a specific for this disease. During the past twelve or fifteen years, however, I have seen numerous recurrences and in a number of instances the development of new lesions has been continuous in spite of x-rays and other remedies. It is, nevertheless, a very useful remedy for this disease. Thus far, I have obtained better results by irradiating the eruption than by irradiating the spinal region. Others have obtained better results with the spinal method.

At one time, the majority of basal cell epitheliomas were treated with either x-rays or radium and the results were excellent. The results are even better today, partly because of improved technic and partly because of a changed attitude on the part of those who treat this affection. Previously, most physicians who were considered qualified to diagnose and treat basal cell epithelioma were expert with only one method. When the lesion proved stubborn, the same method was used over and over again until the disease was almost if not completely beyond control. Today, many of these physicians are equally expert with several recognized methods. Such comprehensiveness plus judgment based on experience, permits the selection of the most suitable method or combination of methods for the particular case. This has resulted in better statistics. The recognized methods are x-rays, radium, scalpel excision, electrosurgery and plastic surgery. cause of frequent diagnostic errors, even by experts, it is advisable, whenever there is the slightest doubt as to the nature of the lesion, to examine a piece of the tumor under the microscope. When dealing with squamous cell epithelioma, basal-squamous cell tumors and mealnoma, I prefer not to depend on x-rays or radium alone, except in selected cases.

The status of x-ray therapy in psoriasis remains unchanged. It is useful only for eruptions that disappear as a result of three or four fractional treatments (approximately 90 "r") administered once weekly, and in which the remission is complete and of very long duration.

My opinion relative to the management of acne vulgaris has not changed over a period of many years. It is important that every patient receive adequate general medical attention. My statistics show that x-rays will permanently cure eighty-seven percent of unselected cases in four months or less without injury to the skin. Without x-rays, the percentage of cures drops below sixty.

Time does not permit further discussion of individual diseases. It is necessary to generalize. About twenty-five years ago Pusey, one of the pioneers of cutaneous roentgentherapy remarked: "It is hardly too much to say that roentgentherapy is the most widely useful addition to the treatment of skin diseases that has been made." Pusey's statement may be repeated today. In

spite of new, successful treatments for some dermatoses and the more discriminating use of xrays, and excluding syphilis from the discussion, the agent is still the most valuable single remedy in dermatology. Over eighty skin diseases are more or less amenable to such treatment. In many of these affections the radiation is used as an adjuvant, or to obtain remissions when other methods have failed. The remissions may be temporary, of long duration or even permanent. Many of the inflammatory dermatoses fall within this category—eczema, psoriasis, lichen planus, etc. It is the best remedy for diseases such as ringworm and favus of the scalp, mycosis fungoides, granuloma annulare, localized hyperidrosis, synovial cyst, keloid, localized essential pruritus, acne vulgaris and a few other conditions. X-rays will cure many diseases and conditions such as basal cell epithelioma, granuloma pyogenicum, warts, keratoses, etc., in which they are indicated only in selected cases because there are other methods that may give as good or even better results. Radium is especially valuable for cavernous angioma and the so-called strawberry mark. In my opinion, it is contraindicated in cases of portwine mark, lymphangioma and other

Over the years there has been a constant improvement in x-ray technic. Apparatus, tubes and electrical instruments of precision have been made more efficient, durable and accurate. However, the most important technical contributions of the past decade are the establishment of an international intensity standard known as the roentgen unit ("r") and ionization instruments calibrated in roentgens suitable for practical use. The number of roentgens with the effective wave length constitute the dose. It is necessary, of course, to record other factors, particularly the distance. The arbitrary unit used by American dermatologists and known as the skin unit, erythema dose and epilating dose, has not yet been translated into a definite number of roentgens. We have been experimenting for several years with intensities ranging from 250 to 500 roent-The number of roentgens for the unfiltered skin unit will most likely be in the neighborhood of 350 with 100 kilovolts (Victorian dosimeter; measured in air).

With the exception of increased accuracy, there has been very little change in the technic used by American dermatologists, a technic that has stood the test of time. Well trained dermatologists who have been guided by the rules of this technic until they have acquired experience sufficient for sound judgment, have had no bad results. These rules have been published and are available, therefore they need not be enumerated here. X-ray injuries of various kinds are still too common. Their frequency is out of proportion to the accuracy of modern technic. Com-

paratively few such injuries are caused by ethical dermatologists, and when they do occur they are caused much more often by poor judgment than by inaccurate teclmic.

The Chairman has requested that I discuss the half strength glazed flat radium element applicator. This applicator is about the size of a postage stamp and contains approximately 10 mg. radium element. Years ago it was considered an indispensable part of the dermatological equipment. It is less popular today. The reasons for this lessened popularity are numerous. In the first place, it can not be used for the treatment of the large number of extensive eruptions and large lesions that are handled so successfully with x-rays. Another reason is that many dermatologists failed to follow the evolution of radium therapy, especially in its relation to cancer. Some of them did and a few still do attempt the treatment of frank cutaneous cancer with this entirely inadequate amount of radium. The modern use of radium or radon in cutaneous cancer therapy requires an intense source of heavily filtered radiation placed at a distance of from one to several centimeters from the surface. The applicator must be constructed and applied in a manner that will provide approximately equal intensity over a surface of known size regardless of whether or not such surface is flat, irregular, convex or concave. The dose will range from a few hundred to many thousand milligram or millicurie hours, depending on the clinical and histologic characteristics of the lesion, the amount of filtration, the distance, etc. In many instances, it is advisable to implant radon seeds or transfix the lesion with radium needles instead of applying the radiation from a distance.

To a considerable extent, the requirements for the radium treatment of cancer pertain to the treatment of certain benign cutaneous conditions such as keloids, cavernous angiomas, etc. If time would permit, I would discuss in detail the comparative value of x-ray and radium therapy in dermatology and elaborate on the indications and contraindications. It will have to suffice to say that the dermatologist should be experienced or trained in the modern use of radium and radon as applied to his speciality. He may then purchase applicators of various kinds—plaques, tubes and needles; or he may rent the more flexible radon.

The particular applicator under discussion has a definite value in dermatology but because of its small radium content and its fixed size and shape, its field of usefulness is exceedingly restricted. Screened with 0.1 mm. aluminum it gives excellent results in small very superficial lesions that are amenable to beta ray therapy—selected keratoses, very superficial basal cell epitheliomas, small superficial keloids, strawberry marks and selected cavernous angiomas. In contact with the skin the time for the crythenia dose is about twenty minutes. Applications vary in time from ten or fifteen minutes to one or two hours, depending upon requirements and conditions too numerous to be even mentioned here.

The applicator may be used for gamma ray treatment by screening with 1/2 or 1 mm. brass and 1 mm, aluminum. When so screened, the time factor for an effective therapcutic dose is burdensome. Even when placed in contact with the skin, the time element will range from an hour or two to fifteen or more hours. When placed at a distance of a centimeter or more from the surface, as is necessary for good results in the case of thick or deep-seated lesions, the time required for a fully effective dose is practically prohibitive. However, in spite of these handicaps, it is possible to obtain satisfactory results in a number of selected cutaneous conditionswarts, corns, keratoses, leucoplakia, keloids, strawberry marks, cavernous angioma, granuloma annulare, basal cell epithelioma, and a few other lesions.

PERSONAL EXPERIENCES IN THE PROPHYLAXIS AND TREATMENT OF RING-WORM OF THE HANDS AND FEET

By EARL D. OSBORNE, M.D., EDWIN D. PUTMAN, M.D., AND RAYMOND J. RICKLOFF, M.D., BUFFALO, N. Y.

Read before the Section on Dermatology and Syphilology at the Annual Meeting of the Medical Society of the State of New York, New York City, April 4, 1933.

N August, 1931, Osborne and Hitchcock¹ reported on the use of sodium hypochlorite in the prophylaxis of ringworm of the feet. It was shown by fungicidal tests that .5% sodium hypochlorite was effective in killing five of the commoner strains of ringworm organisms with an exposure of fifteen seconds This experimental in a watery suspension. work has since been confirmed by Legge, Bonar and Templeton.2 We recommended the use of a 1% solution of sodium hypochlorite to allow for dilution and that the individuals walk through rubber pans filled with this solution or through wells built in the floors for this purpose. In the Buffalo High Schools, pupils were required to walk through the rubber pans or wells on the way to the shower bath after removing the clothing and again just prior to dressing. We are aware that this direction is well adapted to public school pupils with strict supervision but difficult of application to golf clubs and industry.

Reasons for Failure of Prophylaxis

We realize that any method of prophylaxis of ringworm of the feet is doomed to failure, or at least partial success, without the whole-hearted support of the public health authorities, school authorities, school children, and adults engaged in athletics or in industry. We might summarize the reasons for failure as follows:

1. Lack of interest on the part of public health authorities in the prophylaxis of this increasingly wide spread disease. In these days of curtailed budgets, health authorities are loath to assume any new procedures entailing any expenditure of money. In our opinion, no public bath or gymnasium entailing the common use of runways, shower baths, or dressing rooms should be allowed to operate without adequate provision for prophylaxis of ringworm of the feet.

2. Lack of interest and supervision by those in charge of the prophylactic methods as outlined. This especially is true in golf clubs where refilling and cleaning of the pans is delegated to some locker boy who takes the thing as a joke and frequently allows the pans to go untouched for weeks at a time.

3. Improper placement of the pans. Frequently individuals will take care to walk

through the pans and then after drying the feet thoroughly will walk considerable dis-

tances in their bare feet on the locker room floors. A few well worded and well placed signs should eliminate this factor.

We have received many inquiries as to the cost of this method of prophylaxis. In our experience, it should cost approximately seventeen cents per refill of the pans. In using a 1% solution of sodium hypochlorite the pans should be refilled every two days. Certainly this expense is no bar to the extended use of this method of prophylaxis.

Prophylaxis of ringworm of the feet has now been in use in the Buffalo High Schools for a period of almost three years with very gratifying results. Where complaints were common from parents prior to the use of prophylaxis, these have practically disappeared during the past three years. Another surprising result has been a marked falling off of recurrences among known cases of ringworm of the feet. In private practice and in our clinics we have not seen a single new case of ringworm of the feet in high school students of the city of Buffalo and very few recurrences although there have been some. The director of physical education has reported that the incidence of ringworm among Buffalo High School students has dropped over 50% during the past three years. Certainly the experience in the Buffalo High Schools warrants the widespread adoption of this method of prophylaxis of ringworm of the feet.

We have been interested in checking up on the incidence of ringworm of the feet in the male freshman students at the University of Chart I shows that, in the fall of Buffalo. 1931, after prophylaxis had been used but one year in the Buffalo High Schools, that 55.7% of the students entering from Buffalo High Schools showed ringworm of the feet, whereas 65% of those from outside schools showed ringworm of the feet. In October, 1932, these percentages had fallen to 46.4% and 50% respectively. Most of the students entering the University of Buffalo from outside the city came from small towns and cities from the western part of New York State. It was impossible for us to determine how many of these schools had adopted the method of prophylaxis of ringworm of the feet during the past two years. At any rate, there was a drop of almost 12% in the incidence of ringworm of the feet in the two groups combined. This is certainly in the right direction but it will

CHART I.

Incidence of Ringworm of the Feet in Male Freshmen Students at the University of Buffalo

| Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Incidence | Inci

be necessary to follow this study for at least three or four more years in order to determine definitely the value of prophylaxis of ringworm of the feet. The incidence cannot be reduced beyond a certain point because many of the students engage in extra-curricular athletics in institutions where prophylaxis is not used and a number of individuals acquire the infection at home. In view of the alarming increase in the incidence of ringworm of the feet and, the now well known tendency to produce systemic effects, a serious attempt in the prophylaxis of ringworm of the feet is justified by all health authorities, public school officials, and laymen interested in the development of various types of athletics.

Objectives in the Practical Treatment of Ringwarm of the Hands and Feet

Before considering the various methods and means of treating ringworm of the hands and feet, let us consider some of the important facts brought out during the past few years in regard to this type of infection. It is our impression that a more careful attention to these facts would reduce the number of poor results and, in fact, prevent some of the disastrous effects resulting from the improper treatment of mycotic infection. Some of the factors of

importance are the following:

1. The vast majority of mycotic infections begin on the feet, usually between and under the fourth and fifth toes. If the soil and environment are right the infection continues to spread to the other toes, soles, and sides of the feet. In the course of ten to twenty days, fungi and their toxins are absorbed into the lymphatics and then into the general system sufficient to produce an altered tissue reaction, called allergy, in the skin and mucous membranes of the body as shown by the positive trichophytin test and by the clinical observation of localized or generalized bilateral, symmetrical, dermatophytids. We subscribe firmly to the belief that a very high percentage of the bilateral and symmetrical vesicular erruptions of the hands occuring in the course of a chronic or acute ringworm of the feet are dermatophytids. On the other hand, we do believe that many cases of ringworm are primary on the hands, probably constituting 20% of the total. These eases are usually manifested by a uni-lateral, asymmetrical, peripherally ex-

tending, vesiculo-pustular eruption which may later produce all of the systemic effects noted in ringworm of the feet. We cannot ascribe to the opinion of Wise and Sulzberger*, that all feet harbor mycotic organisms from infancy which become pathogenic under right conditions of soil and environment.

2. In many instances it is absolutely impossible to differentiate between an actual derdermatophytid matomyeosis or hands and dermatitis venenata from almost A cutaneous test with cause. very limited value eliophytin is of in these eases although we do it routinely. In the presence of either a chronic or an active focus of the toes, a positive trichophytin test in an industrial worker does not prove that the eruption on the hands is myeotic in nature. Careful observation and patch tests are necessary in these eases and, from the standpoint of treatment, active treatment for ringworm infeetion frequently does more harm than good and confuses the issue.

3. From the standpoint of the practical handling of these cases, either in private practice or in a large clinic, we place clinical experience and observation ahead of laboratory procedure. We believe it is a mistake to overemphasize the value of smears and cultures to the general practitioner or the general hospital laboratories since all dermatologists and mycologists admit that mycology is far from an exact science. More experience than the average practitioner or laboratory worker possesses, is necessary for mycologic work and its proper interpretation.

4. In considering the practical treatment of a case of ringworm of the feet and hands, the following questions should be considered by

the physician:

A. What areas of the eruption are due to the actual invasion of the fungus organisms and what areas are due to allergic manifestations?

B. In the areas of active fungus infection, what are the local conditions of heat and moisture?

C. Does the patient have a general systemic condition favoring increased perspiration?

D. Is there anything in the patient's general condition increasing the excretion of sugar or protein metabolic products through the sweat?

E. Does the patient wear wool hose?
F. Does the patient subject his feet to prolonged maceration from sweat without adequate hygienic treatment?

G. What precautions does the patient take

to prevent recurrence or re-infection?

H. What previous treatment has been used both in the way of local applications and radiation therapy?

Careful considerations of these questions is necessary to successful treatment of any case of ringworm of the feet and hands. In the case of a widespread dermatophytid, soothing remedies only should be used on the dermatophytid and the focal areas on the feet or hands subjected to parasiticidal therapy. In our experience, prolonged heat and moisture from any cause are the two most potent factors producing flare-ups and intractable ringworm of the feet and hands. Hyperidrosis, from any cause, favors the growth of fungi. It is well to remember that the hydrogen ion concentration of normal sweat is very close to the optimum for the growth of mycotic organisms. Draper showed, several years ago, that a shifting of the hydrogen ion concentration slightly towards the alkaline side with an increase in the phosphates and a lowering of the oxygen tension favors the development of mycelial organisms as compared to the yeast-like forms. This is a very rational explanation of why we find the mycelial forms more frequently between the toes and in the groin whereas the yeast-like organisms are much more frequently found on the glaberous skin and seldom the mycelial forms. The increased excretion of sugar or protein metabolic products in disease certainly favors the growth of mycotic or-This question should always be borne in mind and a careful examination of resistant cases should be made for evidences of diabetes or kidney disease. The question of wool hose is important. It has recently been shown that mycotic organisms grow readily in wool, very slightly in silk, and not at all in cotton. Furthermore, wool hose encourages excessive perspiration. A history of previous treatment is always important. Often we find patients who have been subjected to strenuous parasiticidal therapy with the production of a secondary dermatitis from irritation. Many times these patients will clear up with the continued application of a soothing ointment and dusting powder. Excessive irritation of a chronic or acute focus may precipitate an extensive generalized dermatophytid requiring weeks to subside. With the widespread use of x-ray therapy in these cases, especially in the form of prolonged fractional dosage, there is always a danger of over-treatment in addition to producing an x-ray resistant infection.

5. What do we hope to accomplish by treatment? We believe the opinion first expressed by Saboraud, and since by many dermatologists, is correct namely; that very few cases of ringworm of the toes are ever actually cured. The studies of Jamieson and McCrea⁵ bear out the widespread impression that fungus organisms remain dormant in the epidermis only to spring into activity under the proper con-

ditions of heat, moisture and soil. The vast number of remedies recommended and the many so-called cures claimed for non-fungicidal drugs, such as Absorbine Jr., indicates quite clearly that ringworm infection of the feet and hands tends to get well of its own accord if given half a chance and local conditions of heat and moisture and soil are made unfavorable for the growth of fungi. We have seen many chronic over-treated cases of ringworm clear up following careful hygiene of the feet and the application of a bland ointment and dusting powder. In other words, any remedy works in a large percentage of cases if the parts are cleaned and dried thoroughly twice a day and the environment is made unfavorable for the rapid growth of the fungi.

Local Treatment

Acute Vesiculo-Pustular Stage: In this stage we favor the use of wet dressings for twelve to fourteen hours during the day, of either metaphen, 1-2500 to 1-5000 dilution, or liquor aluminum subacetate, 1-16 dilution. For the remaining eight to ten hours we prefer a plain boric acid ointment, a 2% sulphur precipitate ointment, or a soothing astringent dusting powder containing 1% menthol, 5% chloratone, 5-10% tannic acid and 30% boric acid. Rest in bed with elevation of the parts is usually of material assistance. In some stubborn relapsing cases we have used crude coal tar ointment with marked benefit.

It is in the acute, vesiculo-pustular cases that we believe x-ray is of the greatest value. For the past three years, we have discarded the repeated fractional dose method in favor of one sub-erythema treatment of the parts involved with active mycotic infection. The results are immediate and nearly always satisfactory within two weeks. We have not seen as many generalized dermatophytids as we did following the fractional dose method which is a point of great importance in private practice.

Following the cessation of the acute vesiculo-pustular stage we usually prescribe gradually increasing percentages of salicylic acid and sulphur precipitate to be applied two or three times a week combined with the use, during the day, of a dusting powder containing 30% tannic acid and 30% boric acid. The feet, of course, should be carefully washed and dried each day.

Sub-Acute and Chronic Cases: We believe that Whitfield's ointment is still the standby in these cases and we decry its popularization by pharmaceutical houses under various trade names. We usually combine Whitfield's ointment with sulphur precipitate, from 3-10%,

and direct the use of the ointment two or three nights a week with the use of tannie acidboric acid dusting powder during the day. We realize that there are countless other methods of treating chronic, relapsing cases of ringworm of the hands and feet and we have tried most of them at one time or another. principle methods of local treatment which have been of value in addition to those mentioned are: wet dressings of metaphen and liquor aluminum subacetate, crude coal tar with the addition of 3-5% sulphur precipitate, chrysarobin ointment, from 3-20%; iodine, either in the form of iocamfen or with salicylic acid and thymol in alcohol, Castellani's carbolfuclisin paint, and finally, plain 5-10% ammoniated mercury. X-ray therapy in sub-acute or chronic cases is frequently of marked assistance but should not be relied on for cure. Many times it is over done because of the temporary benefits which the patients experience. Too often the condition is no better after three or four months of x-ray therapy than before it was instituted. In our opinion, if the disease does not respond to four or five fractional doses of x-ray properly spaced, it might better be discontinued. To place sole reliance for cure on x-ray is a gross error.

Use af Trichophytin as a Curative Agent: Since 1928, we have been using trichophytin, both the commercial preparation and that which we have produced ourselves in our own laboratories. During the first three years we very carefully selected patients with proved cases of ringworm infection of the hands and feet, secured positive cultures and produced autogenous trichophytins and monilia extracts after the method of Scholtz. We were ready to publish a preliminary report in 1931, when there appeared the first report by Van Dykes and others on their experiences with trichophyton extract in mycotic infections of the skin. They were enthusiastic regarding the use of trichophytin in the treatment of ringworm infections. Because our results did not agree with theirs we resolved to continue our work, choose our cases carefully, and try to evaluate our results as carcfully as possible. To date we have thoroughly investigated and treated over one hundred chronic relapsing cases of ringworm of the hands and feet with trichophytin. Our impressions are:

1. Theoretically we might expect improvement in dermatophytids from desensitization as Sulzberger and Wise have pointed out. Our results have been sporadic and we helieve no

better than could have been expected without trichophytin.

2. In chronic relapsing mycoses of the hands and feet our results have been very disappointing. Apparently good results, in most instances, proved later to be temporary. We should never forget the natural tendency to improve and relapse, depending upon the environment, and especially under mild antiseptic applications. We can find no theoretical reason for expecting that desensitization would effect cure of a primary focus.

3. Local flare-ups of foci and widespread dermatophytids, asthma, and urticaria have been observed following trichophytin and in one instance a severe vesiculo-pustular ex-

foliative dermatitis.

4. We have treated four patients with asthma associated with mycotic dermatitis in whom positive smears and cultures were secured. There were no permanent results.

Summary

1. We believe that 1% sodium hypochlorite, properly used, is a cheap, harmless, and effective prophylactic against ringworm of the feet and deserves wide application. Three years' use in the Buffalo High Schools has effected a marked drop in the incidence of ringworm in the schools.

Effective treatment of ringworm of the hands and feet necessitates an understanding,

on the part of the doctor, of:

(a) allergy and the development of dermatophytids.

(b) clinical differentiation from dermatitis

venenata.

(c) value of laboratory procedures.

(d) local conditions of soil, heat, and moisture of the parts involved and an appreciation of any systemic disturbance influencing the sweat secretion.

(e) previous treatment.

3. Since we cannot permanently cure most cases of ringworm of the hands and feet with our present methods, our objective should be to render the environment unfavorable for the

growth of the organisms.

4. Methods of local treatment that have given us our best results are discussed. We favor one suberythema dose of x-ray in acute cases of ringworm of the feet and hands rather than the repeated fractional dose method. If four or five fractional doses of x-ray do not produce a result in chronic cases it should be discontinued.

5. Our results from the use of trichophytin

have been disappointing.

OBSERVATIONS ON THE EFFECT OF IODINE ADMINISTRATION IN CASES OF HYPERTHYROIDISM

By GEORGE M. GOODWIN, M.D., NEW YORK, N. Y.

From the Thyroid Clinic, St. Luke's Hospital, New York City.

N 1923 H. S. Plummer¹ drew attention to the effect of compound solution of iodine (Lugol's solution) on the symptoms of exophthalmic goiter and advocated its use in the preparation of cases for operation. Since then the use of iodine has become popular in the treatment of cases of thyroid toxemia, not only in the preparation for operation, but also in cases in which operation is not intended. The usefulness of iodine in the preparation of cases for operation as illustrated by the reduction of operative mortality has been thoroughly proved. Many workers experienced in thyroid disease agree that while iodine is useful in the preparation of cases for operation, its prolonged use in the medical treatment of the toxic case accomplishes no permanent benefit and is objectionable because it delays the institution of surgical treatment which seems at present to offer the best expectation of restitution of health. Some however, qualify their agreement with this attitude. Thompson² and others at the Massachusetts General Hospital administered iodine for long periods to 24 cases of exophthalmic goiter. They classified 14 of these cases as mild, and 10 as severe. In the ten severe cases the result was satisfactory in only one, there was no permanent benefit in four, and five of the ten cases became worse. In the fourteen cases the results were satisfactory in 9, "fairly satisfactory" in 3, and unsatisfactory in 2. They concluded that-1, patients with moderately severe or severe exophthalmic goiter rarely show more than temporary improvement during prolonged iodine administration and frequently become worse than before iodine was started-2, if the disease is mild, patients often respond satisfactorily and in some cases the disease terminates—3, the proportion of unsatisfactory results in Boston appears to be so small that prolonged iodine administration is not contraindicated if strictly confined to mild cases kept constantly under observation, and-4, the response of patients with exophthalmic goiter to prolonged

iodine medication appears to be determined more by what is happening to the disease spontaneously than by the iodine itself and in cases showing satisfactory results iodine may have merely held the disease in check while

pursuing its natural course.

There is undoubtedly a wide variation in the intensity and duration of thyroid toxemias in different individuals. As far as we know there is no way to prophesy in the individual case whether the patient will or will not run a mild course. Cases admitted to our own thyroid clinic are usually of the severe or moderately severe type and many of them tell the same story of having taken iodine for varying periods until admission with improvement at first and then a return of the symptoms to their original intensity. At this time these patients are found to be in an iodine fast or refractory phase and no further remission occurs with its continued administration. It is naturally a source of irritation to the thyroidsurgeon that many cases are brought to him after prolonged medical treatment with iodine. He recognizes that the patient, if operated upon at this time, faces a much greater hazzard than in the stage of iodine remission. In these patients who are iodine refractory it is necessary, as pointed out by Coller's to interrupt the iodine administration for a period when it is usually possible to again obtain a remission. This delay in bringing him to a safe state for operation is often annoying and sometimes critical as far as the patient is concerned. delay prolongs his illness and he is exposed to the danger of a thyroid crisis when the most effective agent for its control has been rendered unavailable.

There seems to be a good deal of misconception as to the use of iodine in thyrotoxic cases. At one time it was considered that it was indicated in the exophthalmic or hyperplastic but not in the toxic adenomatous or nodular goiter. In this geographical area both types seem to show the same temporary

amelioration of symptoms in response to its administration. It has often been stated that only one remission could be obtained in the given ease with iodine. That this is not true is illustrated by the cases reported below in which two remissions were obtained in quick succession. Cases are admitted to every thyroid clinic who have been kept continously on iodine by their physicians despite progressive increase in symptoms. It does not seem to be generally recognized that while the patients are temporarily benefited by the iodine, they soon pass into the refractory phase when no further improvement occurs unless the iodine administration is interrupted, after which time it is possible to again obtain an iodine response. This point is illustrated in the second group of cases here described.

In the first group are three cases of toxic goiter. Cases 1 and 2 were classified after operation as of the hyperplastic type, and Case 3 as of the adenomatous type on microscopic examination of the excised glands. None of these cases had received iodine previous to their admission. The object of this investigation was to determine how long a remission induced by iodine would continue if the iodine was withdrawn after a definite remission had been obtained, using the metabolic rate as an

index of the progress of each case.

The second consideration was to learn whether after the first iodine remission had occurred a second remission could be obtained by again administering iodine as soon as the patients symptoms had regained approximately their original intensity.

The patients were kept in bediat rest for periods varying from four to twenty-four days without iodine to determine the influence of rest alone, and to obtain a resting basal metabolism level. Compound solution of iodine (Lugol's solution) was then administered in ten drop doses three times a day. In each case the metabolic rate nad been reduced to a

normal level in from nine to fifteen days. Upon the withdrawal of iodine in each case there occurred almost immediately an elevation of the metabolic rate, which at the end of sixteen to nineteen days had returned to its original level. Upon readministration of iodine at this point in the same dosage a second remission occurred quite similar to that obtained in the first instance. These facts are recorded in Table I.

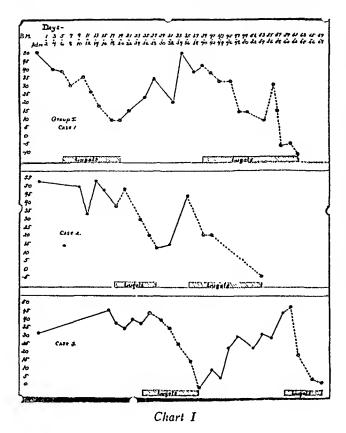

The question which naturally presents itself here is as to how many such remissions could be obtained in a given ease from the interrupted administration of iodine as occurred in these three cases. So far we have had no opportunity to find the answer to this question. Each of these cases came to surgery at the time of their second remission and reacted well to operation.

In the second group are four eases, all of the exophthalmic type each of which has received iodine continuously for months before admission. They all told the same story of improvement upon first taking iodine; and then usually after a period of three weeks, a return of their symptoms and no further improvement. In each case, on their admission to the hospital iodine was continued in doses of gtt.x. t.i.d. to determine whether a remission might be obtained. In none of these cases was improvement in symptoms obtained, nor was there a notable reduction in metabolic rate. In fact in two cases elevation of the rate occurred. At the end of this period the patients were advised to return to their homes for one month. to take no iodine, and then return to us. The period at which they returned varied for reasons beyond our control. After iodine free periods varying from 30 to 52 days the patients received iodine again in the usual dose and then an iodine remission was obtained in each instance. These facts are illustrated by Table II. Unfortunately, for purposes of exactitude, the day of the recorded metabolic test does not

TABLE I

CHANGES IN THE BASAL METABOLIC RATE IN THREE PATIENTS TO WHOM IOONE WAS GIVEN FOR THE FIRST TIME IN TWO SERIES OF ADMINISTRATIONS

	First Period Iodine Administration			Iodine Free Period			Second Period Iodine Administration		
Group 1		-В.	м-	Duration	—в.М.—			—B.M.—	
	Duration	First	Last		First	Last	Duration	First	Last
Case 1	14 days	+34	+-	i6 đays	+11	+45	9 days	+48	+ 4
Case 2	9 days	+48	+14	7 days	+14	+45	7 days	+45	+23
Case 3	15 days	+40	+10	19 days	+10	+43	17 days	+43	+16

always coincide with the first day of iodine administration. The metabolic rate was obtained on admission and again after a period of iodine therapy. In cases 1 and 4 a second metabolic estimation was not obtained after a period of

rest and before the iodine was given. It is sufficiently evident however that there was a response to iodine in the second period while the cases were refractory on the first admission.

While operation might have been undertaken in these cases on their first admission a consideration of the patient's safety would probably have necessitated stage operations. Under the circumstances it was considered better to allow them to escape from their so-called iodine fast condition and to operate upon them later when an iodine remission could be obtained. In following this course they were subjected to annoying delay and in Case 2 there was definite progression of the already existing exophthalmos during the period of delay. Eventually they all came to surgery and had uneventful post-operative courses.

The response to iodine of the individuals of these two groups are illustrated in the accompanying chart. (See Chart 1.)

The graph has been made from the metabolic rates contained in Table I.

The results of iodine administration in these cases show in the first group that the effect of its administration was quickly lost after its withdrawal but that a second remission was obtained promptly upon its readministration. In the second group the results show the cases which were in an iodine refractory phase as the result of its prolonged administration again showed response when the iodine was withdrawn for thirty days or more.

TABLE II

Changes in the Basal Metabolic Rate in Four Patients Who Had Already Been Taking Iodine.
The Table Also Shows the Favorable Response to a Second Series of Administrations
Following A Rest From Iodine

Group II	Iodine Administration	on First A	to Iodine Admission M.—	Period Without	Response to Iodine on Second Admission —B.M.—	
	Before Admission	First	Last	Iodine `	First	Last
Case 1	Four months	+47	+42	45 days	+63	+20
Case 2	Five weeks	+41	+53	52 days	+75	+33
Case 3	One month	+60	+75	34 days	+104	+33
Case 4	Five months	+74	+68	30 days	+59	+34

FREE MEDICAL SERVICE

The practice of medicine imposes an obligation upon both the doctor and the patient: on the doctor that his service shall be of the highest quality according to the standards of scientific medicine; and on the patient to reward the doctor for his service according to the recognized standards of economics of the community.

The maintenance of a high standard of scientific medicine requires that an individual doctor shall deliver the service to an individual patient. This personal relation must be preserved whether the system be that of private practice, or the public clinic, or State medicine. The method of delivery of medical service is not that of the drug store clerk who

hands out what the patient asks for. An essential part of the scientific service which a doctor delivers is a diagnosis, and in accordance with it he delivers the service which he judges the patient to require. An accurate diagnosis is as necessary as treatment, and is usually the more difficult of the two forms of service. There is only one professional standard of medical practice, and the doctor is under obligation to deliver it, regardless of the compliance of the patient with his obligations.

Although the doctor observes a single standard of scientific practice, he unconsciously divides his patients into three classes in regard to their discharge of their economic duties:

- 1. Those who pay him in full 2. Those who pay him in part
- 3. Those who do not pay him at all.

The population of a community consists of these three groups in various proportions; but always each group exists in considerable size. When a community is prosperous and business is active, the doctor is not greatly worried over the economies of his patients, for his practice is adjusted to the three groups and his income is stable. But during the three years of business depression through which the whole world is now passing, great numbers of patients who normally are in classes one and two have fallen into the next lower group; so that now group one of the patients is abnormaly small, and group three is abnormally large, and the doctor has difficulty in making a living.

It has long been the custom of a community to provide the needy with the necessities of life, which have been interpreted to be food, clothing, and shelter. Medical relief in severe sickness was also recognized as a necessity, but the people have expected the doctors to give it to the poor free of charge, largely because of the attitude of the doctors themselves in giving the free treatments because of the advertising value of a long list of patients regardless of their economic status. The young doctor seeks patients of any kind in order to acquire a reputation; and older physicians treat the sick poor in free hospitals and clinics and profit by the prestige which comes from their positions on the staff. General hospitals can always maintain full staffs of physicians who give medical service to the poor without salary or fee. The honor of an appointment on a hospital staff has been accepted as the equivalent of money payment for their services. The system is of long duration and is difficult to change.

The inordinate growth of the free system of medical treatment has led naturally to a general recognition of its injustice. The doctor

contributes taxes and free will contributions to the hospital and dispensary just as any other citizen does; and then in addition he is expected to donate his professional service which has a value equal to that rendered by the architect of the hospital, the lawyer, and the business manager. As a citizen he must bear his own proper share of the burden of expense of providing food, shelter, and clothing to the needy poor in their homes, but in addition the burden of providing them with medical service falls on him alone.

A reformation of the system of giving medical service free has been attempted along two

lines:

1. The home treatment of the needy 2. Hospital and dispensary service.

New York State has progressed so far that its law requires welfare officials to provide medical relief on the same basis that they provide food, shelter, and clothing; but the officials are only imperfectly educated in the interpretation of that duty. The county medical society is the natural agent through which physicians can approach the welfare officers and enter in agreements with them regarding the economics of the service.

At the present time those welfare officers who are willing to pay the doctors cannot obtain funds until the people are educated to make the appropriations. The success of a few county societies in entering into satisfactory agreements is an encouraging example to

others to do likewise.

Less progress has been made in providing pay for medical service in hospitals and dispensaries. The doctors can begin with educating their own number regarding the fallacy of profit from any phase of free treatments. When the physicians of a community request a modest fee for treating the sick poor, the reply which they sometimes receive is a threat to import a doctor who is willing to do the work for little or no pay. The boards could not carry out the threat if doctors understood the economic principles underlying their ac-

The welfare law of New York State points the way to a solution of the problem of free medical service in rural communities; but the problem in the larger cities remains unsolved. One obstacle is the laws governing the actions of the hospitals in the municipal and general To change those laws and the customs of the cities will be a greater task than the reformation of the system in rural sections.

When one considers the great progress in medical economics during the last few years. the outlook is bright for the full development of a more equitable system in the near future under the leadership of the medical societies.

MEDICAL PROGRESS

The Reduction of Fracture of the Neck of the Femur with Carl P. Jones Traction Splint. -Meyer J. Kutisker and John N. Mulholland, writing in the Annals of Surgery, September, 1933, xeviii, 3, refer to the difficulties encountered in the treatment of fracture of the neck of the femur because of the age group in which it occurs. In February, 1932, Carl P. Jones published a report describing a special traction splint designed to secure accurate reduction, sufficient immobilization, and freedom from the confinement so injurious to these old people. The splint utilizes the principle of traction against the well leg. The splint is attached to plaster-of-Paris bandages encasing both legs from below the knee. It consists of a traction barrel with two side arms for attachment to the bandages. The arm which is attached to he injured leg is movable on a screw and exerts the traction. arm which is attached to the sound lcg is fixed and exerts the counter-traction. The bandages are applied with extreme care to avoid pressure. The leg is covered with a single layer of cotton wadding; four strips of one-quarter inch thickness felt are cut in strips to cover the lateral and medial surfaces of the leg, the instep and the heel, and are bound to the leg with gauze bandages. Four plaster-of-Paris bandages, six inches in width, are used to encase the leg from below the knee to the toes. Internal rotation of the thigh is then obtained to a sufficient degree to turn the great troclianter to its normal level. The splint is now applied with both legs in internal rotation, thus preventing flexion of the After the plaster has hardened traction is exerted until reduction has been effected. This is determined by the x-rays. The only anesthetic required is one-quarter of a grain of morphine. The advantages of this splint are: (1) Exact reduction is obtained with regularity and ease, and with little discomfort to the patient. (2) Patients are comfortable immediately. They may sit up or use a wheel chair a short time after reduction. Nursing care is simpler and easier, and the danger of pressure sores and pulmonary complications is reduced to a minimum. All parts of the body except the lower legs and feet are exposed and accessible for physiotherapy. (4) Expense to the patient is greatly reduced by the elimination of operating room, anesthesia, and prolonged hospitalization. The authors have treated ten cases by this method with satisfactory reduction in every instance.

Sport as a Therapeutic Measure.—In the use of sport for therapeutic purposes, says Wolfgang Kohlransch, in the Deutsche medicinische Woch-

enschrift of August 11, 1933, two distinct types of exercise are called for: (1) increase the tonus, in morbid conditions which have arisen through lack of stimulation, such as functional retardation of growth, general relaxation, etc.; and (2) those which diminish the tonus, in conditions of overexcitability, for example asthma, essential hypertonia, neuroses, and the like. For the patients in the first group, exercises with apparatus are suitable, also boxing, wrestling, and all kinds of exercise calling for muscular effort. For those in the second group, on the other hand, gymnastics that relieve tension are called for: preferably exercises with rhythm. continuous courses of therapeutic gymnastics with shaking and stretching exercises and the like. In atrophic and hypotonic infants after the ravages of wasting diseases, rickets, and other like conditions, a course of infant gymnastics skilfully carried out often restores within a few weeks the normal turgor and tonus, and causes a considerable taking on of weight. Infant gymnastics is a resistance gymnastics, exerted statically; for example, pushing the legs against the hand of the gynmast, lifting them high on his fingers, etc. Particularly satisfactory are the effects upon the os sacrum of walking with a ball between the knees, with the feet close together, or of jumping frog-fashion with feet together and knees spread wide apart, and other children's games. A relaxed position of the spine, stooping shoulders, and flat cliest are overcome by practice with the medicine ball, wrestling, rowing, swimming, gymnastics, short distance running, ball playing, etc. Contracted chest muscles must be brought to relaxation by stretching exercises. Functional circulatory weakness is advantageously treated by speeding-up gymnastics, that is, by the doing of more work in a given unit of time. The exercise is limited to 20 minutes and is preceded and followed by a complete rest of 10-20 minutes. Constitutional vascular weakness can be overcome by forceful movements of feet and legs. In the catarrh of city dwellers, the tendency to take cold frequently disappears when the patient adopts a hardier mode of life. The best type of exercise for these persons consists of activities carried out upon the turf, such as golf and the like.

Epilepsy of Childhood.—Julius Zappert states that he considers luminal as relatively the best dring for treatment of epilepsy of childhood. According to the age of the child, he begins with 0.05 to 0.075 gm. administered as a single evening dose (using somewhat less in children under 2 years of age), and gradually increasing this to

0.5 and 0.175 gm. which he divides between a morning and an evening dose. Even larger amounts are well tolerated, but the maximal dose is not always the optimal one. Such treatment may be safely continued for years, with a reduction or omission on one or more days per week during periods free from attacks, but with no complete discontinuance. Signs of overdosage vomiting, drowsiness, dizziness, exanthems. If luminal should prove entirely ineffectual it may be combined with bromides (1-2 gm. sodium bromide every 2-3 days). Too long use of bromide-luminal treatment sometimes causes such toxic symptoms as fatigue, difficulty of speech, and tremor. Zappert uses bromides without first having tried luminal only in cases where the convulsions are very frequent, beginning with relatively large doses (3-4 gm. per day of sodium bromide or Erlenmeyer's mixture), then decreasing these until the amount that seems effective is reached, after which smaller amounts of bromide can again be given with luminal. Among the newer remedies, he has not had any striking success from sodium biborate, or thyroid gland therapy. Nor can he report favorably on those few cases in which he has used the new surgical procedure of intracerebral perflation. Dietetic therapy has long played a part in the treatment of epilepsy. Hunger cures, and salt-free and ketogenous diets have all been tried, with more or less favorable results. prefers a salt-poor diet to one that is wholly saltfree, since the children exhibit less repugnance toward it. The number of epileptic children in whom an energetic treatment may be expected to produce good results is greater than the number of hopeless cases. It is to be regretted that such cases are often handicapped by the high price of medication, the need of continual oversight and the difficulty involved in securing school attendance. A large field lies open to social efforts in this direction, which should include not only the erection of homes for curable epileptics but also the establishment of special dispensaries with low-priced medicines, in which the necessary mental encouragement can also be offered to these unfortunate persons. — Münchener medizinische Wochenschrift, August 4, 1933.

Tango Treatment in Hospital and in Gentreal Practice.—According to E. Frauchiger, and pranism of the action of fango is a purely their pose, unaccompanied by any chemical or can alwayfactors such as some writers have who give nt. Experiments in the University salary or feebles have been as some writers have who give nt. Experiments in the University salary or feebles have been as some writers have writers have been as some writers have been as some writers have been as some writers have writers have been as some writers have a some writer on a hospital cks have been applied in the last equivalent of melly disproved the existence of The system is ofors. A fango pack is simply to change. to change. The inordinate of its and medical medical and a second sec

specific heat of the moist pack is composed of the heat of the dry powder and that of the water it contains. The dry fango powder consists of silicates with a greater or less content of calcium The fact that the specific heat of these minerals is much less than that of water makes them exceedingly well adapted to bind in the fango pores a maximum amount of water with high specific heat, in such a way that it can be practically utilized in the form of a poultice. It is a complete waste of effort and material to spread merely half a kilo or a kilo of fango over a large body surface, for the quantitative bulk of the mass is one of the main considerations. Even for small local packs large amounts must be used in order to maintain an even temperature. Thus, for a knee, elbow, or wrist one should employ 10 kg., and for both hips or shoulders at least 20 kg. is necessary. The technique of the application is so simple that it can easily be carried out in private homes. The essential considerations are to use a large amount of the substance at a temperature of 42°-50° C. if possible, but not such as to burn, and to cover it well on the outside with thick woolen packing. To heat a fresh mass of fango, it is necessary only to add to the mass one-half its weight of hot water, mix thoroughly in a tin pail and place the latter in a larger vessel of hot water over the fire, stirring until the fango has a temperature of about 60° C., and the consistency of potato soup. It is then spread in several layers, each of the thickness of a finger, on a piece of old woolen cloth with a backing of watertight material. The whole is laid on the bed and after the temperature is reduced to about 45° C. the affected part, previously smeared with a thin layer of the fango, is slowly placed in it. The patient should lie wrapped in a wool blanket for ½-1 hour. In most cases the packs should be given every day or every two days for a period of several weeks. The indications for fango treatment are found chiefly in the various rheumatic, arthritic, and posttraumatic joint affections, as well as in neuritis, neuralgia, and myalgia. Contra-indications exist in severe cases of hypertonia and in affections of the myocardium.—Schweizerische medizinische Wochenschrift, August 5, 1933.

Two Rather Unusual Renal Affections.—In the Acta chirurgica Scandinavica of July 28, 1933, E. Edberg describes: (a) a case of hydronephrosis accompanying a chronic ulceration of the kidney pelvis, with repeated hemorrhages, and (b) a case of iliac kidney with confluent abscesses and perinephritis. The first case concerned a boy of 7 with an intermittent congenital hydronephrosis, in which, following a traumatism, a small rupture had occurred in the ch led to the first attack of hematuria. sture became transformed by degrees into

nic ulceration provided with a niche, and

at a still later period the slight shocks continually inflicted upon the dilated sae resulted in further hemorrhages, for which nephrectomy was at length done, one year after the rupture had oecurred. The author has found no case in the literature like this. There are cases enough of traumatie rupture of hydronephrotic sacs in children, but it has seemed to be the universal rule for the traumatism to result immediately in a peritonitis or in such formidable hemorrhage that operation had to be done immediately without delay. The uroselectan radiographic images were somewhat difficult to interpret. In chronic or acute occlusion of the ureter the opaque substance cannot for a certain length of time leave the kidney, on account of the pressure in the kidney pelvis. The result is that there is no shadon of either the calices or the pelvis, but instead there may be a greater condensation of the image of the kidney itself. The longer the flow is interrupted, the poorer will the image be This seems to account for the difficulty of interpretation in the case under discussion. In the second ease, the patient was a girl of 14, admitted with vomiting, diarrhea, chills, and high fever. Uroseleetan revealed on the right side an ectopic kidney with pelvis shaped like the bowl of a pipe, from which the ealices passed both inward and outward. There was a chronic colibacillus infection, which had previously given no serious trouble, but now within a period of ten days, there had arisen grave symptoms indicative of abseess formation in the right side. There was every indication that the suppuration, which involved the upper pole of the kidney, was on the point of producing a perirenal phlegmon had not nephreetomy been promptly performed. Intravenous pyelography furnished perfectly clear evidence from a diagnostic point of view. Transvesical exploration, done later, gave no important information that had not already been furnished by the other method, although the images were richer in details.

Experimental and Pathological Studies on the Nature and Rôle of Bacterial Allergy.-Arnold Rice Rich states that by "allergy" he means here only that state of specific hypersensitivity which develops as the result of the entry of foreign protein into the tissues, and which manifests itself locally by tissue damage and inflammation. When the protein enters the blood stream there ordinarily occur the constitutional symptoms of fever, malaise, and prostration. It is now well known that while the body is acquiring an active immunity to bacteria during infection, the tissues ordinarily become hypersensitive to the protein of the infeeting microorganism. In his investigation of the pathogenesis of tuberculosis Rich has encountered circumstances which cast serious doubt on the widely accepted view that allergy is necessary for the operation

of immunity. He has succeeded in separating immunity from allergy by three different methods and in a variety of infections. He describes experiments which demonstrate that it is possible to establish acquired immunity without the coneomitant development of allergy. He has also been able to separate immunity from allergy by injecting the serum of allergic, immune animals into normal ones. The immunity was transferred to the latter, but not the hypersensitiveness. Finally immunity was separated from allergy by means of desensitization. In each of these different types of experiment it was found that immunity operated in full force in the complete absence of allergic inflammation. These experiments on desensitization nere extended to tuberculous infection by Drs. Rothschild, Friedenwald, and Bernstein, who were able to show that immunized guinea-pigs can be kept for months in a state of complete desensitization without suffering any detectable loss of their immunity to virulent bacilli. On the other hand, it has been shown that a high degree of allergy can exist in the complete absence of immunity. The presence of bacterial hypersensitiveness is merely an evidence of infection. It means only that baeterial protein has been liberated into the tissues, iust as non-baeterial hypersensitiveness means only that the specific protein has found its way into the tissues. The degree of hypersensitiveness is not a measure of the degree of immunity. For example the tuberculous patient may have a low degree of resistance with a high degree of hypersensitiveness and vice versa. From the practical standpoint, Rice suggests that the studies presented in this paper open the way to an investigation of the results of freeing the infected body from the damaging effects of hypersensitiveness, with the knowledge that the abolition of allergy will not entail the loss of the protective power of acquired immunity.—The Lancet, September 2, 1933, cexxv, 5740.

Neurosyphilis: An Analysis of Vanderbilt University Hospital Material Over a Period of Seven Years.—W. M. Dedman and Hugh H. Morgan present an analysis of 335 patients with unquestionable neurosyphilis. This number of patients represents an incidence of neurosyphilis at the Vanderbilt Clinie of 6.8 per cent. Of the 335 eases, 43.8 per eent. belonged to the parenchymatous group; the remainder were classified as meningovascular. Lumbar puncture was not performed on every patient or the incidence would probably have been much higher. The figures indicate that the syphilitic white is 38 times as prone to develop neurosyphilis as the syphilitic negro. The colored female is relatively immune to syphilis of the nervous system. Neurosyphilis was manifested most frequently between the ages of 20 and 50 years. The greatest number of cases for any decade occurred

0.5 and 0.175 gm. which he divides between a morning and an evening dose. Even larger amounts are well tolerated, but the maximal dose is not always the optimal one. Such treatment may be safely continued for years, with a reduction or omission on one or more days per week during periods free from attacks, but with no complete discontinuance. Signs of overdosage vomiting, drowsiness, dizziness, If luminal should prove entirely exanthems. ineffectual it may be combined with bromides (1-2 gm. sodium bromide every 2-3 days). Too long use of bromide-luminal treatment sometimes causes such toxic symptoms as fatigue, difficulty of speech, and tremor. LEGAL

FEDERAL COURT RULING ON CHIROPRACTIC

By Lonenz J. Brosnan, Esq. Counsel, Medical Society of the State of New York.

The members of the medical profession have been for years witnesses to the attempt on the part of the chiropractors to obtain a status putting them on a par with regularly qualified medical practitioners. Year after year, bills have been submitted to the legislature of this State for the purpose of giving a legal status to the chiropractors by setting up a licensing machinery. Prosecutions charging unlawful medical practice have been bitterly fought in the courts by the chiropractors.

In our neighboring State, Pennsylvania, very recently a novel attempt was made by the chiropractors to gain their aims. In that State, much as in ours, the law defines the practice of medicine in properly comprehensive terms. The law provides in part:

"It shall not be lawful for any person in the State of Pennsylvania to engage in the practice of medicine and surgery, or to hold himself or herself forth as a practitioner in medicine and surgery, or to assume the title of doctor of medicine and surgery, or doctor of any specific disease, or to diagnose diseases, or to treat diseases by the use of medicines and surgery, or to sign any death certificate, or to hold himself or herself forth as able to do so, * * unless he or she has first fulfilled the requirements of this act and has received a certificate of licensure from the Bureau of Medical Education and Licensure created by this act."

Under that act, various proponents of the art of chiropractic had been indicted or threatened with indictment charging them with the alleged practice of medicine. A number of chiropractors joined themselves as co-plaintiffs in a suit against the members of the State Board of Medical Education and Licensure in one of the Federal District Courts. The suit sought a decree enjoining the members of the Board from enforcing against chiropractors the penal provisions of the act relating to physicians and surgeons, and futher enjoining the Board from interfering with their exercise of what they termed their professional rights in the absence of laws specially regulating and governing the practice of chiropractic.

The bill in equity filed in the suit made the claim that chiropractic is a skilled and honorable profession; that it is a healing profession based upon principles distinctly different from other healing professions, "having to do chiefly with the recognition of the brain and nervous system, the dependence of the nervous system upon the normal functioning of the organs of

digestion, assimilation, respiration and circulation, and the restoration of normal conditions by a scientific manifestation of the spinal vertebrae." The bill further charged that by reason of the fact that prosecutions were made and threatened upon their failure to obtain a license to practice medicine, when it was in fact impossible for them to obtain such a license, they were being deprived of their constitutional rights. Specifically, the constitutional question raised was, whether they as citizens were being denied the equal protection of the laws, and whether they were being deprived of their property in their right to engage in the practice of their profession, without due process of law, all in violation of the guarantees contained in the Fourteenth Amendment to the Constitution of the United States.

An application was made before a District Judge to test the validity of the plaintiffs' claim, with the result that the bill was dismissed. The chiropractors took an appeal to the Circuit Court of Appeals, but the said Appellate Court unanimously affirmed the ruling that had been made by the District Judge. The Circuit Court of Appeals in so ruling said in part:

"We shall, because of the able and earnest presentation of the case for the appellants, discuss and decide the question raised. In order to do so we must first inquire the character of the statute involved. It relates to the art of relieving and curing human ills, which is commonly referred to as the 'healing art', of which the plaintiffs admit themselves to be members. This is a generic expression and ordinarily embraces the whole art of healing and its many theories and practices. As it extends to all personal citizens of a state, it falls very clearly under its police powers. These a state may exercise by promulgating a system of regulation and control which, if not unreasonable and arbitrary, is lawful and is binding upon everyone in the state. To assure its citizens skilled treatment of their ills by qualified practilioners and particularly by guarding them against malractice by ignorant and unskilled practitioners the Commonwealth of Pennsylvania, acting within its police power, declared by the act in question a state policy in respect to the healing art and provided a general system for its complete regulation, referring to it as 'the practice of medicine and surgery'. That a state may thus regulate 'the practice of medicine, using this word in its most general sense', can no longer be questioned ***

most general sense, can no longer be questioned. * * * "So, also, defining the class to which its legislation is directed, though purposely comprehensive, it cannot be successfully asserted that the state was arbitrary or unreasonable in requiring that all, who, dealing in one way or another with the anatomy and system of the human bindy and diagnosing its ills, offer their services to the

WASHINGTON COUNTY

The annual meeting of the Medical Society of the County of Washington was held at Hudson Falls on Thursday, October 5th, at 4 p. m., with the president, Dr. D. F. Macarthur, in the chair, and twenty members present. There were also present thirteen guests, of whom eight were from Glens Falls.

The reports for the year were submitted; that of the Treasurer showing a balance on

hand of \$125.

1286

The following officers were elected:

President: Roy E. Borrowman, M.D., Fort Edward.

Vice President: C. H. Holmes, M.D., Cambridge.

Secretary: Silas J. Banker, M.D., Fort

Edward.

Treasurer: Charles A. Prescott, M.D., Hud-

son Falls.

Board of Censors: John H. Ring, M. D., Granville, Chairman; Hilton W. Gillett, M.D., Hartford; Leslie A. White, M.D., Whitehall.

Committee on Legislation: W. A. Leonard,

M.D.

Committee on Public Health: H. A. Rogers, M.D.

Delegate to State Society: D. M. Vickers,

The following resolution was presented by Dr. Bennett and adopted:

Resolved, That the present agreement of the County Medical Society and Commissioner of Public Welfare be terminated on January first, 1934; and that the doctors located in several communities be authorized to enter into such agreement with the local welfare units as they may deem necessary according to existing conditions of this community.

The president, Dr. Macarthur, read his address on "Coronary Thrombosis". The address stressed the fact that this disease was recently recognized as more frequent and of

more importance than before.

After an evening dinner, Dr. Francis A. Hulst presented an interesting talk on "The

Physician-on the Witness Stand."

Dr. Thomas H. Cunningham of Glens Falls spoke on "One Phase of Medical Public Relations." He told of the efforts of the Warren County Medical Society to abolish the free clinics in eye cases and venereal diseases, and to allow members of the society to receive fees for such work.

Dr. John M. Swan of Rochester, Chairman of the State Cancer Committee, gave a talk on

"The Early Diagnosis of Cancer."
Dr. James T. McKenna of Troy concluded the program with a talk on "The Mind, its Origin, Growth and Decay."

S. J. BANKER, Secretary.

SENECA COUNTY

The annual meeting of the Seneca County Medical Society was held at the Willard State Hospital, Willard, N. Y., on Thursday, October 19, 1933. The meeting opened at 10:45 A.M., with the President, Dr. C. B. Bacon, in the Chair, with a good attendance of the members of the Society and guests.

The following officers were elected for the

year 1934:

President: Dr. John F. Crosby, Seneca Falls. Vice President: Dr. E. M. Wellbery.

Secretary and Treasurer: Dr. F. W. Lester. Censors: Drs. C. B. Bacon, L. W. Bellows, and F. W. Lester.

Delegate to State Society: Dr. C. B. Bacon. Alternate: Dr. W. R. Holmes, Waterloo. Delegate to 7th District Branch: Dr. A. Letellier.

Alternate: Dr. R. F. Gibbs.

There was a general discussion of the Welfare Relief in Seneca County. It was resolved, on motion, that the Fee Bill adopted by the Society on January 5, 1933, be continued in force during the year 1934.

Scientific Program

The Scientific Session opened at 1:45 p.m. with the following program:

1. "Eye Fundus Changes in Systemic Disease" Dr. John A. Spengler, Geneva, N. Y. Dr. Spengler not only gave a very interesting and carefully prepared paper, but he exhibited numerous photographs of eye backgrounds enlarged showing changes due to disease. These photographs were made from actual plates taken by Dr. Spengler of cases occurring in his own practice.

2. "Encephalitis Lethargica Chronic," Dr. Ross Herold of the Willard State Hospital staff. Dr. Herold gave a short paper on the course and manifestations of the disease. Two patients were then shown, both males, and both exhibiting the characteristic symptoms of far advanced cerebral deterioration.

3. Dr. Herold also described Huntington's Chorea, and showed a case which exhibited the typical jerking of the muscles and the constant motion of the hands, arms and shoulders.

FREDERICK W. LESTER, Secretary.

ROCKLAND COUNTY

Social Meeting: On September 15th, sixtyone members and guests of the Medical Society of the County of Rockland met at the Recreation Hall of the Summit Park Sanatorium, the tuberculosis hospital of Rockland County, Pomona, for their annual clambake.

Dr. Thomas Parran, Jr., Commissioner of Health of New York State, in a brief address, congratulated the Society on the success of its

social activities.

Dr. Joseph S. Lawrence, Executive Officer of the State Medical Society, commended the local Society for its get-together spirit at such meetings. Dr. Lawrence spoke of the opportunity that is offered the physicians to take part in the welfare program of the State in order to help maintain the integrity of the home. Individual members of the medical profession can assure a large part in this work by cooperating with the medical society.

Brief remarks were made by Dr. Frost, Dean of Public Health of Johns Hopkins University, who was a guest of Dr. Parran, and Dr. Robert E. Plunkett, Director of the Division of Tuberculosis of the State Department of Health.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education of the State Society, commends the Rockland County Medical Society for its coperative and active spirit, and put the local Society as one of the first county societies in the State for its progressive activities and loyalty. He especially emphasized the great benefits which the Society is obtaining from the post-graduate courses which are being held annually. (The program of the Fall Course appears in the Journal of October 15, page 1233.—Editor's note.)

Among the other guests present were: Drs. Frank B. Berry, Oswald R. Jones, and Howard W. Potter of New York City; Dr. Frank Laidlew, District State Health Officer, of Middletown; and Drs. E. C. Rushmore and Harold Morrison of Tuxedo Park and Dr. Royal S.

Copeland, U. S. senator.

Regulor Fall Meeting: The Medical Society of the County of Rockland held its regular Fall Meeting at the New York State Reconstruction Home, West Haverstraw, on September 27th, 1933. About forty members were present.

Dr. F. K. Anderson of Letchworth Village, was elected to membership in the Society.

Dr. Charlton Wallace, Surgeon-in-Chief of the Reconstruction Home, conducted the scientific session, assisted by Drs. Smith and Nicola of the hospital staff. Dr. Smith presented cases of chronic osteomyelitis, and Dr. Nicola a generous variety of convalescent cases of anterior poliomyelitis. Dr. Wallace most ably discussed the interesting advances made in the treatment of chronic osteomyelitis by the use of the maggot treatment, also the use of toxoid of the staphylococcus. In discussion, Dr. Edward F. Roberts of the Lederle Laboratories elaborated upon toxoid. Ward rounds were then made.

A delightful luncheon was served. The afternoon was both profitable and enjoyable.

WILLIAM J. RYAN, Secretory.

SCHOHARIE COUNTY

The regular annual meeting of the Schoharie County Medical Society was held in the Hotel Augustan, Cobleskill, New York, on Tuesday, October 10, 1933. The Business Session was in the Hotel Augustan. The President, Dr. W. L. Oliver called the meeting to order.

The following officers for 1934 were elected: President, Dr. Roy G. S. Dougall, Cobleskill; Vice President, Dr. Duncan L. Best, Middleburg; Treasurer, Dr. Le Roy Becker, Cobleskill; Secretary, Dr. Herbert L. Odell, Sharon Springs; Censor, Dr. Willard T. Rivenburgh, Middleburg: Delegate to the State Society, Dr. David W. Beard, Cobleskill.

Adjournment was taken for Luncheon after which the Society reconvened in the William H. Golding Central School where Dr. William H. Hoffman, of the Cancer Research Department of the Memorial Hospital, New York City, gave a very learned and intensely interesting address on "The Early Diagnosis of Cancer" augmented by a large select number of lantern slides.

At the conclusion of the lecture, at the solicitation of the physicians present, Dr. Hoffman gave a very able talk on "Bone Tumors," illustrated by lantern slides,

H. L. ODELL, Secretory.

BOOKS RECEIVED

- Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.
- PROCEEDINGS OF SOUTHERN BRANCH AMERICAN PUBLIC HEALTH ASSOCIATION. Held at Birmingham, Alabama, November 14, 15, 16, 1932. Octavo of 100 pages. N'ew York, The American Public Health Association, [1933.] Paper, 50c.
- THE DISEASES OF INFANTS AND CHILDREN. By J. P. CROZER GRIFFITHS, M.D., and A. GRAEME MITCHELL, M.D. Octavo of 1155 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$10.00.
- Allen's Commercial Organic Analysis. Edited by C. Ainsworth Mitchell, D.Sc. Volume X, Fifth Edition. Octavo of 817 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, [c. 1933.]
- THE MEDICO-LEGAL AND CRIMINOLOGICAL REVIEW. Incorporating the Transactions of the Medico-Legal Society. Honorary Editors: Gerald Slot, M.D., and Everard Dickson. Volume 1, Part 1, January, 1933. Octavo of 88 pages. London, Baillière, Tindall and Cox, 1933.
- Colds and Hay Fever. By Frank Coke, F.R.C.S. 12mo. of 148 pages. Baltimore, William Wood & Company, 1933. Cloth, \$2.00.
- BLOOD PICTURES. An Introduction to Clinical Hæmatology. By Cecil Price-Jones. Third Edition. Octavo of 72 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$2.40.
- THE JOY OF LIVING. An Autobiography. By Franklin H. Martin, M.D. Two volumes. Octavo of 1017 pages, illustrated. Garden City, N. Y., Doubleday, Doran & Company, 1933. Cloth, \$7.00.
- THE PRACTICE OF PODIATRY. By REUBEN H. GROSS, M.Cp., and E. K. BURNETT. Edited by MAURICE J. LEWI, M.D. Octavo of 451 pages, illustrated. New York, Harriman Printing Company, 1933.
- Nervous Breakdown: Its Cause and Cure. By W. Béran Wolfe, M.D. Octavo of 240 pages. New York, Farrar & Rinehart, [c. 1933.] Cloth, \$2.50.
- Textbook of Physical Therapy. By Heinrich F. Wolf, M.D. Octavo of 409 pages, illustrated. New York, D. Appleton-Century Company, [c. 1933.] Cloth, \$5.50.
- THE TECHNIC OF LOCAL ANESTHESIA. By ARTHUR E. HERTZLER, M.D. Fifth Edition. Octavo of 292 pages, illustrated. St. Louis, C. V. Mosby Company, 1933. Cloth, \$5.00.
- SURGERY OF THE STOMACH AND DUODENUM. By J. SHELTON HORSLEY, M.D. Octavo of 260 pages, illustrated. St. Louis, C. V. Mosby Company, 1933. Cloth, \$7.50.

- Bone Growth in Health and Disease. The Biological Principles Underlying the Clinical, Radiological, and Histological Diagnosis of Perversions of Growth and Disease in the Skeleton. By H. A. Harris, M.R.C.S. Octavo of 248 pages, illustrated. New York, Oxford University Press, 1933. (Oxford Medical Publications.)
- THE ENLARGED PROSTATE AND PROSTATIC OBSTRUCTION.
 By KENNETH M. WALKER, F.R.C.S. Second Edition.
 Octavo of 223 pages, illustrated. New York, Oxford University Press, 1933. (Oxford Medical Publications.)
- A PRACTICAL MEDICAL DICTIONARY. By THOMAS LATHROP STEDMAN, M.D. Twelfth Edition. Octavo of 1256 pages, illustrated. Baltimore, William Wood & Company, 1933. Fabrikoid, \$7.50.

- Manual of Urology. By R. M. LeConte, M.D. 12mo. of 317 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$4.00.
- THE TREATMENT OF RHEUMATISM IN GENERAL PRACTICE. By W. S. C. COPEMAN. Octavo of 215 pages. Baltimore, William Wood & Company, 1933. Cloth, \$3.25.
- DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS. By GEORGE W. NORRIS, M.D. & HENRY R. M. LANDIS, M. D. Fifth edition. Octavo of 997 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$10.00.
- OBSTETRICS AND GYNECOLOGY. Vol. 3. Edited by ARTHUR H. CURTIS, M.D. Octavo of 1201 pages, illustrated, and General Index, Volumes 1, 2 and 3. Octavo of 137 pages. Philadelphia, W. B. Saunders Company, 1933. Cloth. Complete set, including index, \$35.00.
- THE MEDICAL CLINICS OF NORTH AMERICA. Volume 17, No. 2, September, 1933. (Chicago Number). Published every other month by the W. B. Saunders Company. Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net; paper, \$12.00 net.
- LYMPHATICS, LYMPH AND TISSUE FLUID. By CECIL K. DRINKER, M.D. and MADELEINE E. FIELDS, Ph.D. Octavo of 254 pages. Baltimore, The Williams & Wilkins Company, 1933. Cloth, \$3.00.
- PHYSICAL CHEMISTRY OF LIVING TISSUES AND LIFE PROCESSES. As Studied by Artificial Imitation of Their Single Phases. By R. Beutner, M.D. Octavo of 337 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1933. Cloth, \$5.00.

BOOK REVIEWS

FOOD IN HEALTH AND DISEASE. By KATHERINE M. THOMA, B.A. Octavo of 370 pages. Philadelphia, F. A. Davis Company, 1933. Cloth, \$2.75.

Miss Thoma, who is director of dietetics at the Michael Reces Hospital, Chicago, presents in this volume a textbook on dietetics for mirses. It represents a collection of her lectures to student dietitians. It contains elementary chapters on the physiology of metabolism, then continues with standard information on diets in discase and closes with a large section on cookery. It is well prepared and well written. WILLIAM S, COLLENS.

THE MEDICAL SECRETARY. By MINNIE GENEVIEVE MORSE. 16mo of 162 pages. New York, The Macmillan Company, 1933. Cloth, \$1.50.

The author of this book sets out to tell her reader concerning the numerous fastidious requirements for becoming a medical secretary. The reader who still feels confident of tackling this job after reading this scarching handbook should be given a trial. The physician who does not know what to expect from or how to train his secretary will find this book an invaluable guide. The physician who is obliged to do his own secretarial work may profit immeasurably from jointers here and there. Nothing is overlooked. In fact, the secretary familiar with half the requirements listed in this book may be considered quite capable.

EMANUEL KRIMSKY.

J. HAMILTON CRAWFORD.

CLINICAL ASPECTS OF THE ELECTROCARDIOGRAM, Including the Cardiac Arrhythmias, By HAROLD E, B. PARRER, M.D. Third Edition. Octavo of 295 pages, illustrated. New York, Paul B, Hoeber, Inc., 1933. Cloth, \$5.50.

Owing to recent advances in the study of the electrocardiogram much of the book has been rewritten in this edition. This applies particularly to the part of the book which deals with changes signifying myocardial damage. The recent work on the electrocardiographic diagnosis of coronary artery disease is admirably presented. The newer views regarding the localization of ventricular premature beats and lesions of the branches of the Bundle of His have been accepted and are described in detail. An excellent chapter is included which gives a brief account of the fundamentals of the theory of electrocardiography. The book is unquestionably of great value in that it fills a gap between the elementary and advanced books on the subject. This and the fact that it deals almost wholly with the clinical aspects of electrocardiography should make it appeal to the elinican. As before, the volume is beautifully printed and illustrated.

THE INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practitioner's Index. Edited by CAREY F. COOMES, M.D., and A. RENDLE STORT, M.D. Fifty-first Year, 1933. Octavo of .572 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, 86.00.

This volume is a carefully compiled, thorough and accurate review of the year's advances in all lines concerned in the care of the sick. It is impossible for one to realize the vast amount of time and energy that must have been given by the various contributors in preparing this material. The subject matter is arranged alphabetically in dictionary form beginning with abdominal surgery and ending with yellow fever. Each article pre-

sents the latest information and advance in the subject under consideration. This book will prove a most useful, handy volume for reference. Typographically the work is excellent, the illustrations are good.

HENRY M. Moses.

BINOCULAR VISION AND THE MODERN TREATMENT OF SQUINT. By MARGARET DOBSON, M.D. Octavo of 107 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$2.75. (Oxford Medical Publications.)

To one interested in the tecluical application of the standard instruments for studying fusion and muscular anomalies, this little volume makes a very satisfactory reference source. It is well written, the explanations are clear and the illustrations are satisfactory. One could wish for an elucidation of the principles together with diagrams. It is looped that a companion work will soon be presented, giving data to support the conclusions which the author arrives at. Unfortunately there are very few controlled studies available which show by actual evidence the value and limitation of inuscle and fusion training. In fact, there is considerable evidence to show that fusion is entirely a psychic process and that the methods advocated by this work develop not the visual motor apparatus primarily, but rather, through education, the subject's psychic processes.

Jounn N. Evans.

SURGICAL OPERATIONS. A Text-book for Students and Nurses. By E. W. Hey Groves, M.D. Third Edition. Octavo of 263 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$4.50. (Oxford Medical Publications.)

This book has been written as a text for students and nurses, comprising 249 pages, with illustrations upon nearly every page. In this volume the author has attempted to deal fully with all common operations as well as with the technique of surgery, in a brief manner. In the case of the surgery of special regions, e.g., eye, nose and ear, a few typical operations are described, otherwise the book is limited to a description of the type of treatment which should be applied, without describing in detail the operative procedure.

For such a small volume, the subject of surgery has been surprisingly well covered, the illustrations being very specific. As a handbook it should prove a valuable addition to the student's or nurse's library.

R. F. H.

The Harvey Lectures. Delivered Under the Auspices of The Harvey Society of New York, 1931-1932. Series 27. Octavo of 226 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$400.

Whenever one chooses to think of medicine as a science he may find ample proof in these Harvey Lectures.

In the chapter on the Adrenal Gland, the author describes a novel method of extracting a cortical hormone of increased efficacy. Adrenal-ectomized cats showed a much prolonged response to this refined substance and animals could be kept alive almost indefinitely with continued injections.

In the determination of the sensitivity of the sensory nerve fibres a small cutaneous nerve was dissected away except at its skin attachment and slung onto two electrodes leading respectively to an amplifying and record**BOOKS**

ing system. By careful observation it was found that 10-20 microvolts as recorded on the oscillograph would be required to produce an appreciable effect on the loud

speaker.

In studying the hearing mechanism in the cat a very ingenious experiment has been resorted to by exposing all parts of the middle ear on the one hand and on the opposite end by placing an electrode on the auditory nerve through a trephine opening over the lateral lobe of the cerebellum. Test words and tones of measured pitch and intensity which struck the exposed middle ear were therefore transmitted to the auditory nerve via this electrode and these nerve impulses were in turn conducted to a five-tube amplifier and recorded accordingly.

There is a chapter on the newer methods of histoehemistry which deals with microincineration and histospectrography. There are other topics of equal interest with which one may deal at length, such as, factors concerned in the evacuation of the gall-bladder, experimental epidemiology, and malacic diseases of the bones.

The exhaustive experiments which form the basis for each of these lectures are tinged with an idealism and romanticism which make them distinct from the average medical reading matter. EMANUEL KRIMSKY.

WHAT TO TELL THE PUBLIC ABOUT HEALTH. A collection of short articles aimed to present in simple terms the facts about the prevention of disease and the promotion of health. Octavo of 255 pages, illustrated. New York, The American Public Health Association, 1933. Cloth, \$2.00.

This book tells in prose and poetry in a simple and yet impressive way the story of public health. It is very interesting and is an excellent source for material to assist a physician in preparing a radio talk or a health talk before a lay audience.

The material is gathered from a great many contribu-

tors and eovers the subject admirably.

The appendix is made up of a collection of data which ean furnish material assistance to health educators. Newer books about health education are listed as well as organizations that supply health education material. SAMUEL ZWERLING.

Broadcasting Health. By J. Mace Andress, Ph.D., and I. H. Goldberger, M.D. 12mo of 401 pages, illustrated. Boston, Ginn & Company, [c. 1933]. Cloth, 80e.

We applied this book to a practical test which for this particular volume proved to be the best type for a review. We gave this book to a young boy and had him read it to us as he sat on our lap as we helped him over the hurdles of the long, new and strange words.

The book proved to indeed fulfill its purpose for it ereated in the mind of the boy an incentive for questions which were answered as he read further on. This

was especially true of the chapter on milk.

The "get-up" of the book is indeed original and cannot fail to leave an everlasting impression not only upon children and their teachers but also upon any grownup in any walk of life who may read this book.

The reading of this book in the class room will make

an excellent health project program.

The book is written in story form which is made even more interesting by assuming the rôle of a radio broad-

Chapters in this book ean be taken for radio broadeasts or health talks with very little or no changes on the part of the prospective lecturer.

SAMUEL ZWERLING.

DISEASES OF OLD AGE. By F. MARTIN LIPSCOMB, M.D. 12mo of 472 pages. Baltimore, William Wood & Company, 1933. Cloth, \$4.50.

This little book on the diseases of old age mentions

the more frequent and important diseases that occur in the period after 65, describes their variations, and includes their special treatment. The normal manifestations, social aspects and morbidity of old age are discussed.

While not very complete or in great detail, the book has the value of apparently being the result of personal experience.

M. A. Rabinowitz.

THE PRINCIPLES AND PRACTICE OF OTOLOGY. By F. W. WATKYN-THOMAS, M.D., and A. LOWNDES YATES, M.D. Octavo of 555 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$8.25.

This is an English work written by two physicians connected with the London Ear, Nose and Throat Hospital and who are therefore conversant with the work

done in England.

Most authors seem to emphasize the inflammatory diseases, especially the operations. In this work these have not at all been neglected. The descriptions of symptoms, means of diagnosis and operative technique are all clear and ample. The writers however have devoted about 230 pages of the 536 to the other branches of Otology.

The chapter, The Ear and Balance, makes clear, with diagrams, the question of equilibrium and the tests of the inner ear and its brain connections. The one on Hearing takes up very fully the histology of the cochlea and the theories of hearing and the nature of deafness. The use of tuning forks in the making of graphs for air and bone conduction in conductive, periotic and per-

ceptive deafness is fully described.

In the chapter, Increasing the Use of Hearing, the authors emphasize the value of using and training what hearing is present, and discourage the use of electric hearing aids except in elderly patients. Lip-reading is mentioned only under deaf mutism and its use is rather discouraged, for the reason that one who can lip-read

will not use all the hearing ability he has.

The illustrations, many of them original, are good and are a great aid in understanding the text.

The bibliography is not complete, but gives references to works easily available and of use to English-reading students.

The index, an essential part of any text or reference book, is good.

In the preface the authors give as their aim the writing of a work that will help the general practitioner who wants to treat his own ear cases and one that will be of value to the intending specialist. This they have succeeded in doing.

J. W. Durkee. succeeded in doing.

A New Approach to Dietetic Therapy in Epilepsy, Eclampsia of Pregnancy and Infancy Migraine, Angina Pectoris, Bronchial Asthma, Allergie Diseases, Gout, Essential Hypertension, Pernicious Anemia, Polycythemia, Acne Vulgaris, Nervous and Psychie Disturbances, Constitutional Changes, Aging, etc. By Eugene Földers, M.D. Octavo of 434 pages. Boston, Richard G. Badger, The Gorham Press [c. 1933]. Cloth, \$5.00.

Eugene Földes has written a very stimulating book dealing with the metabolism of water and minerals. The various disturbances of water and mineral metabolism in epilepsy, eclampsia of pregnancy, migraine, angina pectoris, allergic states, asthma, gout, hypertension, pernicious anemia and other conditions are discussed. book does not lend itself to abstracting, as it is replete with such an abundance of data that it must be read in the original to be appreciated. The wealth of material will make it of value to every practitioner.

The author draws certain conclusions as to the therapy of the conditions mentioned. While dietetic control is especially stressed and discussed, adjuvant treatment,

medical and otherwise, is not neglected.

M. A. RABINOWITZ.

THE VITAMINS IN HEALTH AND DISEASE. By BARNETT Sure, Ph.D. Octavo of 206 pages. Baltimore, Williams & Wilkins Company, 1933. Cloth, \$2.00.

Questions of health and medical science figure prominently in the popular mind at the present time and the advertising agencies have been quick to take advantage of this interest. The dangers of vitamin deficiency and the importance of this, that, or the other special preparation in curing all the ills to which human flesh is heir, are advertised with great fervor. Only confusion is possible to the layman who attempts to study these exaggerated claims with their mixture of truth, half

truth and deliberate misrepresentation.

A valuable measure of reform has been introduced by the work of the Committee on Foods of the American Medical Association. There is also need for an accurate scientific discussion in popular language of current knowledge concerning the vitamins and their importance in health and disease. Dr. Sure is recognized as an authority in this field and his book goes far toward satisfying this need. If the conclusion that "If we consume daily one to two pints of milk, at least one egg, one-third to one-half glass of orange or tomato juice, a generous portion of vegetables, fresh or canned, whole cereals for breakfast two or three times weekly, meat at the noon or evening meal, introducing liver, kidney, heart, or sweetbreads at least one weekly, we need have little fear of vitamin deficiences" were generally appreciated, most of these advertisements would lose their force.

The volume is written from the research, rather than the medical, point of view. It is doubtful if a physician writing a book for a reader so uninformed that it is necessary to explain that cardiac disease means heart disease should include nine pages dealing with feeding formulas for infants or include such statements as "Goat's milk . . . has smaller protein and fat particles than cow's milk, is much more digestible, and should be used

whenever possible.'

In view of the number of people who are destitute and dependent upon private charity or public relief at the present time, it is probable that deficiency diseases are now on the increase. Unfortunately Dr. Sure does not discuss the minimal requirements for an adequate diet or the method of providing it at the lowest possible cost. CARL H. GREENE.

CLINICAL DIAGNOSIS. Physical and Differential. By Neuton S. Stern, M.D. Octavo of 364 pages. New York, The Macmillan Company, 1933. Cloth, \$3.50.

This volume was written by the author as the result of his experience as a teacher and for use in connection of his experience as a teacher and for use in connection with clinical, bed-side teaching. It is complete, detailed, accurate, carefully written in a style not difficult to study. Much of the subject matter is classified and tabulated. The volume is divided into four parts, as follows: Part I, which includes history taking, physical examination which emphasizes the clinical findings, the various instruments and mechanical devices together with the methods of using these aids in diagnosis, also in this the methods of using these aids in diagnosis, also in this section we have in detail the findings and methods used in the examination of the patient according to the dif-ferent systems. Part II presents in detail the symptoms and signs of tuberculosis and heart disease. This is a complete, accurate and carefully written section of the volume. Part III explains the principles and practice of differential diagnosis and presents twenty-one cas-tice of differential diagnosis and presents twenty-one cas-histories to illustrate the mental processes in making a diagnosis. Part IV gives in detail various symptoms and signs of discased conditions with their significance. These are presented alphabetically and categorically;

they are complete and informative. This volume is an excellent one for the manner, accuracy, inclusiveness and teaching method of instruction in clinical diagnosis. The more carefully one would study this volume, the more one would be repaid for the time spent upon it. The typographical work is excellent, the paper good, and the method of printing allows one easily to understand the divisions and subdivisions as presented by the author.

HENRY MONROE MOSES.

INTERNATIONAL CLINICS. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 2, 43rd Series, 1933. Edited by Louis Hamman, M.D. Octavo of 314 pages, illustrated. Philadelphia, J. B. Lippincott Company [c. 1933]. Cloth, \$3.00. A Quarterly of Illustrated

There is so much of interest in this issue that it will be impossible to deal with more than a few of the

In the article on the causes of hypertension the author is on safe ground when he deals in generalities. We cannot disagree with his contentions when he tells us that hypertension may be contributed by a filtering defect in the kidney, an altered viscosity of the blood, an overacting heart, heredity and age predisposition. But when he attempts to touch upon specific causes we come to the sad realization that we often depend on fits of enthusiasm to provide ourselves with causes which may be actual but which we cannot prove. He tells us that the "'pace of modern life' has not been proved a factor in etiology, nor has 'tobacco.'" If that be true, then the teachings to date have been false or were founded on feeble premises. At any rate it would be invaluable in furthering the solidarity of medical thought to prove things logically before arriving at decisive deductions. He also tells us that "alcohol may predispose through its production of obesity." How it causes obesity, or what type the produce it in certain types, or what type of obesity it causes we are not told. If we are to believe such contentions we have no scientific proof but must respect the dictates of authority,

Mosenthal has quite a valuable chapter on the treatment of essential hypertension. It is practical and comprehensive. As regards "foci of infection" he tells us—"it is doubtful whether their eradication has any effect whatsoever upon blood pressure." Such advice will probably be unnoticed for years to come especially when one must contend with the tremendous impetus with which the focal infection idea has hypnotized our schools and hospitals.

The article on Standards in Therapeutics is especially timely in view of the fact that endless varieties of medicines are constantly brought to the physician's attention with often little or no proof of their efficacy and not infrequently with the statement that "it is worthy of trial." "A small authoritative year book stating in the fewest words the standard treatment for a large number of conditions" is recommended.

That hyperinsulinism is a definite pathological entity, entirely distinct from the artificial condition due to ex-cessive insulin therapy, is discussed by Wilder who summarizes the scant literature on this rare condition. The treatment of this condition is as yet unsatisfactory

The literature is not wanting in medicines for epilepsy and in the chapter on Progress in Pediatries some of these numerous measures are discussed. The conclusion arrived at is "that in most cases of epilepsy treatment is still far from satisfactory." Such a sane confession is truly indicative of progress.

EMANUEL KRIMSKY.

OUR NEIGHBORS

HEALTH INSURANCE IN WASHINGTON STATE

The question of insurance for medical service came before the medical profession of the State of Washington in an acute way two or three years ago owing to contracts made by large lumber and other industrial corporations for the care of their sick workmen. Some of the county medical societies met the problem by organizing County Service Bureaus as described in this Journal of July 15, 1933, page These societies propose to extend the 900. same service into other fields of health insurance, so that agreements as to forms of medical service, the fees, and the methods of administering the service, shall be in the hands of the County Societies. Eventually the County Service Bureaus might extend the service into the field of voluntary health insurance. One object of the Bureaus is to enable the medical profession to direct and control the practice of medicine in its public health and public relations aspects.

The October issue of Northwest Medicine contains four papers which were read at the annual meeting of the Washington State Medical Association on August 28, 1933, on the general subject of health insurance and with special references to the County Service Bureaus. Dr. A. H. Peacock, in his presidential address said:

"The outstanding development of the year has been the growth of the county medical service bureau. This type of service was an economic reaction to the corralling of industrial and supplemental health contracts by small groups and clinics mostly operated and controlled by industrial surgeons. The average practitioner saw the complete breaking up of private practice. Forced by necessity, groups in county medical societies banded together, formed county service bureaus, bid for contracts, until the movement has become state wide with ten units and eight hundred members."

Dr. H. G. Wright, of Seattle, a leader in the Service Bureau, read a paper in which he urged that the State Society organize a State Service Bureau for the purpose of coordinating the work of the county bureaus. Dr. Wright said:

"Many large firms are state-wide in character and scope. Some employees are shifted from county to county or their duties may take them from one county to another. If such a firm had its contact with a state-wide organi-

zation, its employees' medical care would be assured anywhere they might be. The county bureau which is not now able to get any contracts, though many exist, would be able to take of and have for themselves those contracts which under the present scheme of things they never will have.

"Then, when that time comes, as it surely will, when harmful legislation is proposed, this state organization, which is economic in its nature, will have greater power in bringing about the desires of the organized medical profession than anything ever seen in this state before."

In a paper on the general subject of health insurance, Dr. H. J. Whitacre of Tacoma, approved the bureaus, and said:

"Developments in the workmen's compensation and industrial insurance movement in the state of Washington have done more to precipitate the health insurance question than any other single factor. They have, in fact, developed health insurance in our midst, and we must now tardily meet the medical care evils that have grown out of the industrial insurance movement Medical service bureaus in each county and a coordination of the policies and plans of these county units by a state medical service bureau, as has been discussed by Dr. Wright, is the logical next move of the profession in the state of Washington.

"County medical society bureaus, organized primarily for the purpose of handling the industrial worker, are the logical way to begin our attack upon the health insurance problem. When we have gained experience with this phase of health insurance, we will be ready to talk about any extension of the insurance principle that may be necessary. In the meantime, we will be organized for group bargaining and for united opposition to private insurance companies that wish to enter this field for profit at the expense of the patient and the physician."

The House of Delegates voted to approve the establishment of a State Service Bureau and the approval of the work of the county bureaus. Commenting on this approval of contract practice, the Journal says editorially:

"The profession of this state has adopted contract practice in spite of former strenuous condemnation of it, believing that it leads the way to the solution of a great abuse. At the

same time it is well known that this form of practice is not looked upon with favor by leaders of the profession in more conservative sections of our country. At the recent annual Conference of Secretaries and Editors under auspices of American Medical Association, disapproval was emphatically expressed against the medical profession participating in any such fields of practice which have hitherto been viewed with universal condemnation. Now that Washington State Medical Association has formally ventured upon a course which has not hitherto been adopted by the organized profession, the ensuing results of such an undertaking will doubtless be observed with interest and possibly anxiety on the part of the profession in other localities. The experiences during the coming year ought to establish whether or not this new venture has been a wise one and will become productive of results of sufficient satisfaction to establish it as a permanent form of medical practice"

PUBLIC HEALTH EDUCATION IN MINNESOTA

The annual report of the Committee on Public Health Education of the Minnesota State Medical Association is contained in the September number of *Minnesota Medicine* which says:

"Among the events of the last part of last year was the second annual physical examination of 4-H Club candidates for healthiest boy and girl of the state. The examination was held at State Society headquarters, 11 West Summit Avenue, Saint Paul, September 8, with the aid and cooperation of the Minnesota Public Health Association. Credit attaches to the examiners who selected the winner from the hundred well-groomed specimens who presented themselves for judging at the State Society headquarters. These examiners earned for medicine and for the medical profession of the State the good will of the 4-H Club groups as well as each of the 100 farm boys and girls who competed.

"Cooperation with the Minnesota Public Health Association in the publication and distribution of the First Aid Manual to all of the schools of Minnesota early in October was a departure of the year. This manual was published in response to the need for an authentic guide to the teacher both in time of emergency and in the regular teaching of hygiene. Its text was carefully prepared to give only such instructions as should properly be carried out in anticipation of the doctor's arrival. Its con-

stantly repeated instruction was 'Call the Doctor First'! The Manual was also offered to every physician in the state for distribution in any institution in which he might have an interest.

"In this way we hope to counteract the propaganda of commercial agencies who constantly distribute literature urging the use of proprietary antiseptics in every emergency.

"The newspaper service is sent weekly to 340 newspapers in the state. The editorial Sub-committee of which Dr. H. F. Helmholz of Rochester is chairman censors and revises each bulletin bearing our endorsement. These bulletins continue to be prepared and sent out from the state office, with the aid of facilities made available by our alliance with the Minnesota Public Health Association.

"A few years ago an urgent demand was made upon your state association to counteract in some way the great amount of undesirable health publicity that was published in the papers of our state, especially the smaller rural weeklies. In compliance with this demand, a news service was instituted, which at first served less than 100 papers, and now serves about 340 papers out of a total of 494 in the

"Most of the papers in the state, including those in the Twin Cities, are using these stories.

"The remaining number of papers obtain their health news from the MacFadden news service, cultists and similar sources.

"A concrete problem that is likely to present itself to us soon is involved in the possibility of mass x-raying in lay hands or in the hands of persons not directly under the supervision of scientific medicine. A machine that will take mass x-ray pictures at nominal costs is now thought to be close to perfection. Such a machine in commercial and cultist hands, might well cause much harm, whereas, under control of scientific medicine, it could be used legitimately to assist in a high type of diagnostic procedure at proper times and places.

"The principle involved in foreseeing such situations and in forestalling them by prompt action is the same as has prompted us in the past to take a stand against lay use of sun lamps for indiscriminate treatment. It may also be seen in the retention in our own hands of the work of the Heart Association which would otherwise have passed into lay hands, ill-equipped for such work. This committee urges study and alert action to prevent irresponsible and indiscriminate promotion by untrained persons of useful apparatus such as the new x-ray

SALES TAX AND MISSISSIPPI DOCTORS

The Mississippi section of the August issue of the New Orleans Medical and Surgical Journal discusses the sales tax imposed by the State on the gross incomes of doctors, and suggests that each county society approve the following resolution which was adopted by the House of Delegates of the State Association:

"WHEREAS, the sales tax levied on the gross income of physicians of Mississippi by the State Legislature at its last regular session

works an injustice on and imposes a discriminating burden upon the physicians of the State who are already paying privilege tax, income tax, and the regular sales tax imposed on all articles purchased just as other citizens, and

When Milk Is Badly Borne . . . Break Up the Cow's Milk Curd This Easy Way

OVALTINE CURD

MILK CURD

COW'S MILK is admittedly the staple food of young and old, in health and sickness. There is no effective substitute for it. Yet it has its limitations. Strange as it may seem, milk is one of those foods most slowly to be passed out of the stomach, mainly because of the tough, leathery curds which are formed when it comes into contact with the gastric juices.

Cow's milk intolerance is an ever recurring problem to physicians, nurses, and all others concerned with the dietary of the sick. It is a problem, too, to thousands of mothers with children deprived of milk because they cannot tolerate it. Also to many old people with their age-enfeebled digestive organs.

By the simple expedient of adding Ovaltine to milk, many a problem of milk intolerance has been solved. For Ovaltine not only breaks up the milk curd into a finely divided coagulum, as the above illustration shows, but it makes the milk far more palatable and attractive to the taste. Thus, it lessens the monotony of an all-milk diet.

Furthermore, Ovaltine increases the food value of milk by reinforcing it with important food elements, vitamins and mineral salts.

State if the medical profession did not take

care of such charity work, and

"WHEREAS, the physicians of the State feel that the general sales tax is fair and equitable, but they know that a double imposition of such tax is not fair and is not in accord with the spirit of justice; and physicians feel that the Legislature would not have imposed such a tax a year ago but for the fact that the Legislature was being fought, with its back against the wall, by a certain well-organized group or groups of taxpayers in the State, and apparently the Legislature feared the effect of exempting the professional group on sales tax on gross income, in addition to regular income tax. Now since practically all of the men composing the special group or groups which were organized against the passage of the sales tax are now in favor of it, it is felt that the Legislature could well afford to correct the injustice of levying two sales taxes—one on income from services rendered and another on expenditures of physicians;

THEREFORE, be it resolved, that the Mississippi Legislature is hereby respectfully petitioned to exempt the medical profession from the operation of that part of the sales tax which levies a tax on the gross income of physicians. The medical profession has nothing to sell except its services, regardless of whether the purchaser is able to pay for such

services. And be it further

"Resolved that in view of the fact that cities and towns in the State impose a privilege tax on physicians, that the State and county privilege tax be reduced fifty per cent. If this action is taken by the Legislature, the medical profession of the State will cheerfully pay the privilege tax and the general sales tax imposed on other classes of citizens of the State."

CANCER COMMITTEE IN COLORADO

The August issue of Colorado Medicine has the following editorial comment on the Cancer Committee of the Colorado State Medical So-

ciety:

"The Colorado State Medical Society has had Cancer Committees off and on for the past six or eight years. These have been appointed at the request of the American Society for the Control of Cancer. Up to date no particular advantage seems to have been gained, probably for the reason that a definite program of work has never been adhered to, and for the additional reason that such undertakings as there were are seen to have been mapped out along ineffective paths."

"The American Society for the Control of Cancer is now embarking upon a new line of

endeavor, whose broad purpose is education of the profession, especially with regard to the early recognition of cancer and the proper methods of treatment of cancer in its various situations in the body. As we understand it, they wish to continue also the education of the public.

"It is their desire that the Committee of this Society be organized promptly and that after it shall have received instructions and literature from the American Society, it will outline a campaign plan during the summer months which will be brought before the House of Delegates at the September meeting for approval. We see in this

perhaps an admission that past plans of the American Society have been subject to criticism by the profession at large because the initiative in many cases arose with the individual doctors and did not have the stamp of approval of the State Society. The new plans should be such that no personal aggrandizement can be derived by any member of the Committee.

"Among other things, it is known that County Societies will be asked to have cancer programs at their meetings, and perhaps there will be speakers provided by the Committee to introduce the subject to each County Society at a meeting

some time during the year.

COUNTY SOCIETY LEADERSHIP IN WISCONSIN

The efficiency of the County Medical Societies of New York State in assuming the leadership in local health matters is recognized in the following abstract from the annual report of the president of the State Medical Society of Wisconsin to the House of Delegates on June 12, 1933:

"Unless county societies adopt a continuing program of gradually assuming, through education and demonstration, their ability and right to become the recognized controlling and guiding-influence of all activities relating to the sick within a given country, the future will be a repetition of the past with a continuing loss, through the steady encroachment of semi-medical social and public welfare activities, not only of prestige but of prerogatives and function which inherently belong to the general practitioner.

"I have the highest admiration for the work of some of these semi-public agencies, but in all counties in this state where they are not active, I should like to see the county medical

(Continued from page 1302-adt xx) societies give demonstration of doing this work in a completely satisfactory way This thought embraces the idea that when a county society once accomplishes such a project, it will continue with other activities, such as goiter prevention campaigns, prevention of cardiac lesions and complications, prevention and control of cancer, etc. It will be alert to all advances in public health work and will sympathetically cooperate with the officials of the central bureau by putting on campaigns and doing the actual administration of preventive or curative measures The too frequent. somewhat slurring remark that the general practitioner is not capable of doing this work and that it requires a specialist, has done incalculable harm Possibly in the past, with the rapid advances in technic and methods practi tioners who had graduated twenty years earlier honestly felt that the newer knowledge was beyond their ken Today medical colleges surely turn out graduates sufficiently prepared to take up, develop, and administer practically all local activities in this field under central control and guidance as has been so well demonstrated in New York State where no city under 50,000 population has a full time public health physician

"If practical, I would suggest that in order to stimulate the interest of future county society officials and facilitate their work along these lines, a clearing house of county society problems and possible solutions gathered from experience, be established in the Secretary's Department to the end that eventually a suggestive directional guide may be published by the Council embracing many problems not satisfactorily covered by the Constitution and By-Laws Thus, as regards the problem of contract practice, whether it is ethical or not apparently depends upon local conditions"

STUDIES BY COUNTY SOCIETIES IN CALIFORNIA

The October issue of California and West orn Medicine has the following editorial appeal to County Societies to tal e an active interest in public health problems

This fall it is hoped that the officers and program committee will arrange to have in addition to the usual scientific papers and dis-

(Continued on page 1304-adr 1111)

(Continued from page 1303-adv. xxi)

cussions, two or more meetings given over to a study of some of the medio-economic problems to which so much space has been given

in the official journal.

"In every county of California the care of the indigent sick brings into action certain social, economic and medical factors worthy of the interest and understanding of every member of a county medical society. It cannot be too often repeated that constructive efforts aiming at improvement of methods in the care of the indigent sick (and of elimination from the group of charity patients of citizens who have no right to receive aid from public funds or through the gratuitous services of physicians) necessarily must be based on accurate knowledge of facts and figures. To indulge in verbal criticism of conditions without knowing about the existing institutions of each county for the care of the indigent sick, or understanding their relation to the population and economic resources, as well as to the industrial and social conditions of the community, will not make for much improvement in those places where deficiencies and malfunctions exist.

"In some of the counties of the State the component county societies (notably Alameda, San Diego, Fresno, and San Joaquin) have made fairly comprehensive studies of these problems, presenting in their committee reports important information concerning their respective communities and suggesting or putting into operation plans for betterment, of value not only to themselves, but to all other county societies.

"The California Medical Association, acting through its House of Delegates and Council, in the last several years has spent many thousands of dollars in an effort to aid its component county societies to find a satisfactory solution of some of these problems. However, something more than the expenditure of moneys, and even the active interest of a few members. What is needed in order to get is necessary the results desired by all physicians is the real interest and active support of practically every member of every county society. To hope for so universal a cooperation is, however, little less than utopian. Nevertheless, if cooperative aid from every member is out of the question, it is not too much to expect it from the officers of every county society."

ANATOMICAL STUDIES

FOR THE PRACTITIONER

Prime de la constant

MIDWIFERY IN ALABAMA

An editorial in the October issue of the Journal of the Medical Association of Alabama discusses the midwifery problem in the State. Roughly two-thirds of the population of two and a half millions are rural; two-thirds are white; and nearly two-thirds of the new born children are white. One third of the mothers are attended by midwives, concerning whom the editorial says:

"In 1931 there were 3,568 midwives in Alabama under the supervision of county health departments in 54 of the 67 counties. During 1932 this number was reduced, by nearly 1,000 to 2,684. This reduction was accomplished by withholding permits from those whose records showed a preponderance of untoward results such as still-births, neonatal and maternal deaths. Yet, in spite of this reduction the activities of these unskilled attendants increased from 15,325 to 17,913; approximately 2,500.

"For some years the local health departments in this State, working in close harmony with the medical profession and the county boards of health, have attempted to weed out the more grossly unfit among the midwives through a system of a limited amount of coaching and the issuage of area in "For some property of the second

the issuance of permits."

CONTRACT PRACTICE IN IOWA

The September number of the Journal of the Journal State Medical Society contains the following standards regarding contract practice adopted by the Polk County Medical Society:

"Contract practice per se is not unethical. However, certain leatures or conditions if present make a contract unethical, among which are: (1) When there is a solicitation of patients, directly or indirectly. (2) When there is underbidding to secure contracts. (3) When the com-

Joland Water

as a pure water may be used to induce diuresis without any untoward effects.

Bottled only at the famous spring, POLAND SPRING, MAINE under conditions of absolute sanitation.

pensation is inadequate to assure good medical service, (4) When there is interference with reasonable conpetition in a community. (5) When free choice of a physician is prevented. (6) When the conditions of his employment make it impossible to render adequate service to his patients. (7) When the contract because of any of its provisions or practical results is contrary to sound public policy.

"Each contract should be considered on its own merits and in the light of surrounding conditions. Judgment should not be obscured by immediate, temporary of local results. The decision as to its ethical or unethical nature must be based on the ultimate effect, for good or ill, on the people as a whole."

ATTENDING COUNTY SO-CIETY MEETINGS IN TENNESSEE

The January issue of the Journal of the Tennessee State Medical Association contains the following note of a record-breaking attendance on county society meetings which probably would be hard to duplicate elsewhere.

"We have received the personal record of 132 members attending the Knox County Medical Society for a seven-year period. The society has met 50 times in 1932, 339 times in seven years. Dr. Jesse C. Hill has missed only two meetings during the long perioda record probably not duplicated anywhere in the United States. Dr. R. B. Wood has been present at 316 meetings. Eighteen memhers belong to the 200 class, 24 members have been present at more than half the meetings, and 47 members have been present at more than 25 meetings in 1932. Eleven members did not attend a single meeting in 1932 and 3 mentbers have been absent from all meetings for seven years. think of the good things these three members have missed! Their interest in the society seems to be limited to paying their dues."

WHY EAT CRANBERRIES?

Who doesn't relish rich red, tangyflavored cranberry sauce? To the American people since the time of tne Pilgrims, the tasty fruit has had a peculiar intangible appeal. Frosty September days usher in bright autumn colors and — cranberries. These latest of the season's berries lend color to the table and interest in the meal. They seem to prod jaded appetites into activity.

Since Colonial times the cranberry has been regarded as possessing certain health virtues, especially as a febrifuge (fever reducer) because of its cooling effect. However, it is only recently that this fruit has been proved to possess real nutritive value. Investigations extending over a period of three years at the Massachusetts State College demonstrate conclusively that cranberries are richly endowed with vitamin C. This is the which promotes growth, vitamin strengthens the blood vessels, and makes strong bones and teeth. As little as three cranberries a day, that is, about one-eighth ounce, sufficed to promote maximum growth and full protection from symptoms of scurvy in young guinea pigs over a 90 day feeding period. In this test all the vitamin C which the animals had was in the cranberries. Without the cranberries, the guinea pigs lived only 25 to 33 days.

Vitamin C is unstable and is often destroyed by cooking, stirring or straining. Would cranberries lose this Will o' the Wisp vitamin if made into sauce? Exhaustive feeding tests on whole-fruit cranberry sauces made from several recipes showed a retention of 80 to 90 per cent of the vitamin content of the fresh berries.

Other experiments carried on with white rats showed that the cranberry contained small but significant amounts of Vitamin A, the antiinfective vitamin. The latter is thus called because of its function in aiding the body to resist infections of all kinds. This vitamin is found in healthy, inspected cattle in greatest abundance in cod liver oil. dairy regions of America.

Repair Your Electro—Diagnostic Instruments

We maintain a well equipped plant for the repairing and overhauling of all makes of Cystoscopes, Eye, Ear, Nose and Throat Instruments, etc., Cautery and other Electro-Medical Apparatus. When we do your work, you can be assured your equipment is entrusted to competent craftsmen.

> Satisfaction Guaranteed Reasonable Charges Prompt Service

WE ALSO SELL

X-Ray and Physical Therapy Equipment and Supplies. Cautery and Light Transformers—Sterilizers-Diagnostic Instruments and Lamps - Sphygmomanometers -Therapeutic Lamps, etc.

It is fully retained when cranberries are made into sauce or jelly.

Thus we see that we may not only enjoy the attractiveness and flavor of cranberry sauce, but at the same time we are helping ourselves to vitamins -and health.-Adv.

BORDEN'S EVAPORATED MILK

Borden's Evaporated Milk, which is now enjoying such a great vogue in infant feeding, is manufactured only from pure, full cream milk from healthy, inspected cattle in the richest

"This product," says a scientific pamphlet, which is accepted by the Committee on Foods of the American Medical Association, "precisely fulfills the exacting requirements of safety, digestibility and assimilability, uni-formity, stability, and nutrient quality demanded by the physician for the infant feeding formula."

That this is so has been demonstrated by many clinical tests on large groups of babies, as well as by the experience of physicians with innumerable in-dividual cases. Of particular interest is a recent study by Jeans and Stearns (Am. Jour. Dis. Childr. 46:69, July, 1933) showing that the retentions of nitrogen, calcium, and phosphorus by infants on evaporated milk are approximately the same as those of infants fed on undiluted acidified fresh milk,-Adv.

ANNOUNCEMENT

The Following Special Lectures Will Be Given at the New York Polyclinic Medical School & Hospital During the Session of 1933-1934

SCHEDULE OF LECTURES by

RUSSELL L. CECIL, M.D.

Professor of Internal Medicine, N. Y. Polyclinic Medical School & Hospital Wednesdays, at 2:30 P.M.

Medical Amphitheatre, Second Floor

Oct. 18th, 1933—ENCEPHALITIS

Nov. 15th, 1933—TYPHOID

Dec. 13th, 1933—INFECTIOUS ENDOCARDITIS

Jan. 17th, 1934—INFLUENZA AND THE COMMON COLD

Feb. 14th, 1934-LOBAR **PNEUMONIA**

Mar. 14th, 1934—RHEUMATIC FEVER

Apr. 18th, 1934—ARTHRITIS

Adv.

Columbia University in the City of New York

NEW YORK POST-GRADUATE MEDICAL SCHOOL

Offers an Eight Months' Course in

OTO-LARYNGOLOGY

beginning February 1, 1934

Under the direction of Professor Duncan Mocpherson. Included in the course are: anatomy and physiology of the nose, throat ond ear; embryology, nathology ond bacteriology of the nose, throat and ear (given by laboratory start); dissection of the head ond neck; nose, throat and ear operations (cadary n; dolly clinics in a large out-patient department; bronchoscopy, etc.

During the last four months tha motriculate performs under supervision a number of the more common nose and throat operations in the oot-patient department.

For further informantion, address

Four Months' Course in

OPHTHALMOLOGY

beginning February 1, 1934

Under the direction of Professor Martin Cohen The course includes: didoctic lectures ond practical consideration of diseases of the eye; enotomy, physiology and pothology of the aye; bedside teeching, refraction; operative ophtholmology on the codover; practical use of the ophtholmoscope and slit-lamp, etc. A large dispensary service in ophthalmology is available.

OBSERVATIONS UPON THE DEPOSITION OF LIVER FAT IN NORMAL AND DIABETIC ANIMALS

By CHARLES H BEST, MD, TORONTO, CANADA

Abstract of a paper presented in a Symposium on Some Disorders of Liver Function at the Annual Meeting of the Medical Society of the State of New York at New York City, April 5, 1933

T I is remarkable that fatty changes in the liver are associated with so many clinical conditions as well as with numerous abnor mal states in experimental animals have been very few clinical investigations of abnormal fat metabolism in which the histo logical findings have been carefully correlated with the results of comprehensive chemical studies. At the moment it appears to me as if progress could be accelerated by utilizing more generally the results of chemical analysis of normal and diseased liver instead of relying merely on pathological histology the results of which are unusually difficult to inter-pret in this field. It is very hard to adopt the fat stains so that a reasonably accurate idea of the character and amount of the fatty substauces is obtained. The chemical methods available are, of course, by no means completely satisfactory and at present the results give us even less information as to mechanism and production of the fatty changes than do the histological studies When histological and chemical methods can both be applied the situation is sometimes clarified

As you will see from the title of my paper, I have no intention of discussing the various fatty changes in liver in an exhaustive inamier. If I take one minute, however to rino over certain phases of the subject, my subsequent remarks may be of more interest. In experimental animals we may see an increase in liver fat during the first stage of starvation. We can produce fatty livers in several species of animals by adding large amounts of fat to the diet. In some species very little fat is required to produce this change. Evidence is accumulated that certain fats are more pronut to produce increased deposition of liver fat than others. The glicoside philorlizin produces an increase in the fat content of liver and this may also be observed, of course after the administration of chloroform alcohol,

benzol, phosphorus, carbon tetrachloride, hydrazine, and other substances Bacterial toxins may produce an unmasking, and in some cases an increase, in liver fat. An increase in liver fat is said to occur during the late stages of pregnancy in rabbits, but Mac-Lean, working with us in Toronto, has not been able to confirm this conclusion Administration of pituitrin has been reported to be followed by a definite increase in liver fat and the available figures support this interpretation The addition of cholesterol to a diet low in fat does cause a definite increase in the fat content of hver (Yuasa 1928) in several species of laboratory animals Dinimished atmospheric pressure is said by other workers to have produced similar results. We know that before the use of liver preparations, cases of pernicious anæmia often showed at autopsy extensive fatty changes in the liver There are, of course, other clinical conditions such as vellow fever, acute yellow atrophy, etc., characterized by increase in liver fat In clinical and experimental diabetes the fat content of the liver may be extremely high if the dose of msulm is madequate or if the diet is rich in In diabetic dogs which are receiving a reasonable dose of insulin and a diet very low in fat, extensive fatty infiltration and degeneration of the liver may appear (Allan, Bowie, Macleod and Robinson 1924) It is abundantly clear, therefore, that the liver reacts to many forms of injuly by an accumulation of fat in its tissues While it is fascinating to speculate on a mechanism which may be the underlying factor in this effect, I must not digress to discuss this matter at present

Now let us see what weapons are at present available to counteract this tendency toward deposition of hier fat. I am only competent to consider this aspect of the question from the experimental point of view, and fen of my remarks can be directly applied to clinical

problems. In the normal animal the amount of fat in the liver can be reduced by providing a diet high in carbohydrate. This has been reemphasized by Rosenfeld (1929, 1932) quite recently. The carbohydrate may exert these effects by one or more of several ways. There is no longer any ground for believing that large amounts of glycogen and fat cannot under certain circumstances exist simultaneously in liver tissue. It is true, of course, that the glycogen content is usually low when there is extensive fatty degeneration, and that maximum glycogen storage results in a low The fat content may, however, be normal or above normal when the liver contains quite large amounts of glycogen and vice versa. Since it is easy to demonstrate that insulin causes a marked lowering of liver fat in the diabetic animal and a similar but less marked effect in the normal, it is reasonable to think that the carbohydrate may owe part of its effects, at least, to liberation of insulin from the pancreas. It is well established that a diet high in carbohydrate will cause increased liberation of insulin, and it is equally true that insulin will lower the fat content of liver. Carbohydrate has little effect on the fat content of liver in the completely depancreatized dog. Insulin itself has, of course, a profound effect. There has been very little work on this action of insulin, however, and assuming that these results are familiar to you, I will spend the rest of my time discussing the effect of other substances on deposition of liver fat. To return to our diabetic dogs: in the experiments in which liver fat has been studied, the carbohydrate of the diet and the insulin administered are kept absolutely constant. Under these conditions fatty changes occur slowly in the livers of the animals, but in certain cases the accumulation of fat may be very marked within a few months after pancreatectomy. fatty livers can be quickly produced by adding fat to the diet of these diabetics. This liver fat is made up of more saturated fatty acids than those which are found in combination with phosphate in liver tissue. When the dogs' livers become fatty, sugar production in the tissues is diminished and the animals require less insulin to keep them sugar free. Thus fat itself, or substances like synthalin, myrtillin, and so on, which may produce fatty changes, affect very favourably the carbohydrate balance sheet in these diabetics, but the effect is produced by a highly unphysiological It is probable that these fatty changes interfere with a variety of hepatic functions, and this has indeed also been indicated by the results of Rosenthal and Lillie (1931), who found that a diet high in fat definitely increases the retention of the dye bromsulphalein. The increase in blood uric acid which may be observed in patients on a fat-rich diet, has been correlated by Harding, Allin and Eagles (1927) with dimished excretion, but the possibility may be considered that decreased liver function may have been in part responsible in some cases.

In the diabetic dogs on a fat-poor diet which I have referred to above. Allan et al found that fatty livers did not appear when raw pancreas was included in the diet. It has been found by members of our group (Hershey and Soskin) that crude lecithine contains some substance which prevents the occurrence of these fatty changes in the livers of diabetic animals. The results of experiments on normal animals (Best, Hershey and Huntsman, 1932; Best and Huntsman, 1932) indicated that the substance was a component of purified lecithine, and other experiments established the fact that the active material was choline. When choline is administered to a diabetic dog the amount of fat in the liver is reduced. When choline is administered daily to a depancreatized dog the animal remains in good condition for long periods of time, even though an amount of fat which would soon have produced disastrous results in the absence of choline is ingested. We have an animal which, on the fifteenth of this month (April), will have been one year without its pancreas. During the last seven months this animal has ingested 20 grams of fat per day, which in similar animals has rapidly produced fatty changes in the liver. Her condition is excellent, and the results on this one animal provide very strong evidence for the efficacy of choline in preventing the fatty changes.

To return again to a consideration of nondiabetic animals, as stated above, the fact that purified lecithine prevented deposition of liver fat led us to try the effects of the components of this substance. When glycero-phosphate or sodium oleate is administered there is no diminution of liver fat. Amino ethyl alcohol, which might also be present in this material, since the lecithine was not altogether pure. also gave negative results. Choline, however, consistently lowers the percentage of liver fat. The addition of any of the other components of lecithine or choline does not enhance the effectiveness of the choline. Betaine, a substance which is closely related to choline, possesses the same properties with respect to liver fat as choline. We thus see that choline is effective, not only on diabetic animals, but also on non-diabetic ones. Furthermore, Miss Ridout and I have recently found that an increase of liver fat produced by cholesterol feeding is inhibited by choline and betaine We thus believe, in so far as experimental animals are concerned, that we have added another weapon to the armamentarium available for the battle against fatty changes in the liver We know as yet little about the mechanism of the action of cholme, and we have no data which suggest that the body fat is appreciably diminished by choline The rate of oxidation of fat administration may, of course, be changed, but experiments designed to investigate this point have not as yet been completed

These experimental results may suggest to you certain practical applications Careful experiments are very difficult to carry out clinically and the encouraging results on a

few isolated cases which have been obtained may, of course, be completely misleading The experimental results which I have been describing, however, would seem to justify the assumption that excess deposition of liver fat in inimals can be best prevented or removed by the liberation of endogenous insulin by providing adequate amounts of carbohydrate, by the administration of insulin if sufficient is not available, and, in a much more dramatic way, by the provision of adequate amounts of choline or betaine Since choline or betaine have not been used extensively in clinical work, great care should be taken by those who may be eurious enough to explore the possibility that the results of the use of these substances may possess clinical interest

PATHOLOGY OF ICTERUS

By PAUL KLEMPERER, MD, NEW YORK, N Y

From the Laboratories of the Mt. Sinai Hospital New York City Read in a Symposium at the Annual Meeting of the Med cal Soc ety of the State of New York at New York City April 5, 1933

TCIERUS is the term applied to the discoloration of tissues and body fluids by abnormal accumulation of bile pigment Its intensity varies with the amount of pigment from a slightly yellow tint to a deep greenish black, Moreover, modifications in the nature of the pigment may produce variations of the tint which according to Brugsch, is of diagnostic importance The essential condition in tissue icterus is an increase of the pigment concentration within the blood The various structures and fluids of the bodies however are not equally discolored, thus the central nervous system* rarely becomes jaundiced and cartilage and peripheral nerves hardly Bile pigment accumulates within the urine, sweat and milk, while tears, saliva, mucus, gastric and pancreatic juice remain un-stained Exudates and transulates contain ample bilirubin when it is elevated within the blood Bile pigment impregnates the tissues by diffusing through the vascular wall, but, differences in vascularization per se do not fully account for the variations in the intensity of jaundice in the various tissues and body fluids Elastic tissue has a great affinity for

* In leterus neonatorum the brain especially the basal ganglia may be intensely icteric

hilirubin which explains the ready pigmentation of structures such as skin, scleræ and blood vessels which are rich in these fibers (Rosenthal²) On the other hand, nervous influences may impair the permeability of the vascular wall, thus explaining, according to Meakins, the absence of jaundice on the paralyzed portion of the body or other conditions of partial acterus (Umber and Rosenberg) It is interesting to note that the fluid of blisters caused by a vesicant upon the unstained part contain the same amount of bilirubin as the blood-serum The intensity of the icterus in wheals depends upon the lymphagogue or exudative efficacy of the injected substance. Thus morphine and histamin attract more than proteins (Klein, Adlersherg and Perutz)

Bilirubin is excreted by the kidneys as a threshold substance The threshold varies with different species-in man it is 2 mg per cent, but is markedly raised in renal disease (Nonnenbruch, Peremy) The transudation of bilirubin into the ventricular fluid is hindered by the existing blood-liquor barriere of the chorioid plexus (Askanazy, Schmorl) eerebrospinal liquor is usually stained to a degree much less than the other body fluids

or the blood serum

The term jaundice should only be applied to conditions in which the color is due to bile pigment. In those cases in which other endogenous or exogenous yellow substances such as lipofuscin or carotin are responsible, it is advisable to speak of pseudo icterus. This term was suggested by Wahl for the cases in which ingesting of picric acid had caused an intense discoloration. However, it has been shown by Brulé et al, that picric acid produces liver damage which may also be responsible for bilirubin retention. Jaundice may be produced by the oxydation product of bilirubinbiliverdin, (Melas icterus). However, the existence of urobilin icterus is, at present, not recognized. Thannhauser and Rosenthal and his associates have shown the orange tint of the tissues and serum of hepatectomized dogs to be due, not only to bilirubin, but also to the presence of another pigment, xanthorubin. Fischer and Thannhauser have futhermore maintained that several pigments of similar chemical constitution but isomerically different may be derived from the blood pigment. These might come from different sites of formation, a fact which would be of great importance in the classification of the various clinical forms of icterus. Because of this, the exact knowledge of the chemistry of the various pigments is of immediate practical importance.

The chemical structure of the pigment of bile, the bilirubin, has been established by Fischer and Kuester. Later investigations of Fischer and Reindel and Rich and Bumstead have shown that the pigment found in old hematomas, the hæmatoidin of Virchow, is structurally identical with the bilirubin of bile. It is exclusively derived from the pigment of blood, but the process of transformation of the hæmatin into bilirubin is not yet fully understood. Fischer, 10 years ago cautioned against the belief that this process of transformation is very simple. He assumed that the hæmatin molecule is broken up into pyrrol complexes and that these were in turn rearranged to form the bilirubin molecule. Thannhauser recently has expressed a similar belief.

The presence of bilirubin is demonstrated by the characteristic color scale which it develops in the course of oxydation, by the absorption band of the spectrum, or by its ability to combine with diazonium salts to form an azo-compound. This reaction developed by Ehrlich and Proescher has been introduced into the clinical investigation of icterus by H. Van den Bergh. It is common knowledge that Van den Bergh and his collaborators demonstrated that the bilirubin of the bile turns red immediately after the Ehrlich reagent has been added while bilirubin

extracted from pigment stones in aqueous solution requires the addition of alcohol for the reaction. It is sufficient to keep in mind. that the same difference of a direct and indirect reaction was present in the serum of various patients and that Van den Bergh was the first to demonstrate that the direct reaction was found chiefly in obstructive jaundice, while icterus without obstruction usually gave an indirect reaction.

Many investigators have attempted to explain the difference in the reaction. Some writers believed that the direct reaction is determined by the simultaneous presence of other biliary components within the serum such as cholesterol and biliary acids. Barron has shown that bilirubin is adsorbed by the serum proteins and has to be liberated by alcohol in order to react. In adding other substances to the serum, which are likewise adsorbed by the serum proteins, such as biliary acids, cholesterol, or sodium oleate, the indirect reaction becomes positive. According to his opinion the reaction is directly positive, whenever the bilirubin concentration exceeds 16 mg. per cent. A similar belief is held by Elton, Snider and Reinhold, Strauss and Adler think of an interrelation between serum globulin and the type of Van den Bergh reaction. A drop in the globulin fraction is responsible for the direct reaction. Accordingly, the type of reaction might be influenced not only by a disturbance in the bilirubin metabolism but also by an alteration of the protein function of the liver. Griffith and Kay believe that the directly reacting pigment is neither bilirubin nor one of its common salts but that it differs in its physicochemical properties. Fowweather has established that the relation between the direct and indirect bilirubin is dependent upon a more reactive enolform and its tautomeric ketoform. It is interesting that Sobotka and Goldberg of our laboratories have at the same time demonstrated that biliary acids may exert an enolising influence upon other similar tautomeric equilibria. Although the nature of both types of bilirubin is not yet fully understood, the significance of the difference in the reaction must not be underestimated. This is especially true if one keeps in mind that the hæmatoidin formed outside the liver and the bilirubin of the bile react This, no doubt, indicates that an differently. activity of the liver is responsible for the difference. This consideration leads one to inquire as to the site of the bilirubin formation. It is impossible to discuss this question in brief. Moreover, a discussion may be safely omitted because the subject has been ably reviewed by many competent workers within the last years. But it may not be amiss to briefly

present some of the more important recent investigations which have been published since the last comprehensive reviews by Rich

in 1925 and 1930

Extrahepatic bilirubin formation has been proven beyond a doubt by the accumulation of bilirubin within the serum of hepatectomized Further direct evidence has been produced by Mann and his collaborators who have shown that the bone marrow is the chief site of extrahepatic bilirubin formation. By supravital perfusion of the spleen, Ernst and his coworkers have shown that biliriibin is formed from hemoglobin within this organ. Rich has shown that bilirubin in tissue cultures, is formed by meso That the liver cells merely modify, dermal cells concentrate and exercte the bilirubin formed outside the liver is the contention of Aschoff, Mann and Rich, to mention only the more important proponents of this belief Yet one must not forget that Thannhauser and Rosenthal have shown that bilirubin is but a small portion of the pigment which accumulates within the serum of hepatectomized dogs. The greater part is orange colored called anthorubin, which might be a propigment of bilirubin, which is changed into it only by the activity of the liver Moreover Rosenthal and his collaborators, by careful experiments have shown that the bilirubinemia caused by hemolytic substances such as Toluylenediamine and Phenylly drazine is far less intense in hepatectomized dogs than in control animals Rosenthal concludes that, while extrahepatic bili rubin formation cannot be denied, the essential part of bilirubin production belongs to the liver Taniguchi repeated some of these experiments and concurred with his conclusion. In most recent experiments Rosenthal tried to show that the polygonal liver cells proper are responsible for the bilirubin formation within the liver and not the Kupffer cells which belong to the reticulo endo thelial system. It is possible to paralyze this latter system for about 50 hours by injecting an electro colloidal copper solution If the reticuloendothelial system alone would be capable of bile pigment production, bilirubinemia and icterus could not be provoked in the period of arrested However injection of icterogen, a dimethylpyrrohol compound, into mice prepared in such a way causes joundice just as intense as in controls This, according to Roscuthal, proves the ability of the polygonal liver cells to actually Aschoff attacks the validity of form bilirubin these experiments by assuming that the damaged reticulo endothelial cells may liberate ferments which might be able to minufacture the bilimbin within the blood stream. In order to disprove Rosenthal's conclusions based on his Toluylenediamine and Plienylly drazine experiments the Aschoff school has repeated them and attained similar results. However, there is disagreement in the interpretation. It would lead too far afield

to go into the details of their argumentation. If one impartially reviews the investigations of the last two decades one is forced to conclude that bilirubin is formed both extrahepatically by the cells of the reticulo endothelial system and possibly by ferments within the blood stream as well as by the polygonal liver cells. For the present it cannot be decided whether extrahepatic or intrahepatic bilirubin formation is of greater importance under normal and pathologic conditions.

The classification of acterus greatly depends upon the viewpoint one takes in the question of bilirubin formation. If one believes that all the bile pignent is formed outside the liver and that the latter acts merely as an excretory organ as do the kidneys, one may divide jaundice into three groups.

1 Overproduction icterus due to excess forma

tion of biliriibin

2 Retention icterus due to mability of the damaged liver cells to adequately excrete the bilirubin circulating within the blood

3 Resorption acterns due to obstruction of the

biliary channels

If one sides with the dualistic concept of bilirubin formation he has to accept, just the same, the existence of an overproduction as welf as a resorption interus. Only in reference to the interus due to liver cell alteration has he to assume that its cause may he, not only in a retention of bihrubin due to excretory insufficiency, but possibly also in a perverted course of the bile pigment into the blood capillaries instead of the bille capillaries.

For practical purposes the liver is always the center of the ieterus problem. The vital question for the mm in practice remains as to whether the ieterus in a case under observation is due to liver daining or not. The answer to this question determines the choice of treatment and the prognosis. For practical needs the jaundice problem revolves about the simple question. Where does the pathology he, before, within or after the liver cell? With this question in mind, I now should like to review the various clinical forms of ieterus.

Jaundice as a diagnostic, therapeutic and prognostic problem will chiefly concern the general practitioner and the surgeon but occasionally the specialist also has to deal with the question

During pregnancy, icterus may occur as an incidental intercurrent disease, icterus in gravidi late, or it may arise as a result of certain pathologic alterations of the organism attendant upon pregnancy, icterus e graviditate (Heynemann) * It has long been known that a considerable per centage of cases of the primary acute yellow atrophy occur in late pregnancy or in puerperium Icterus is known and dreaded in the severe cases

^{*}Cases of acterns recurring at every pregnancy lave Leen tell; Schwal;

of toxemia of pregnancy and in eclampsia. autopsy severe destructive lesions of the hepatic parenchyma are found. In those cases which subside, a latent liver damage may persist for years, manifesting itself by the presence of noncharacteristic symptoms such as nausea, epigastric pressure, headache and dizziness. Functional tests will reveal an insufficiency of the liver (Stroebe). The occurrence of grave hepatic disorders during pregnancy raises the question as to whether a liver alteration of a milder degree does not occur more frequently (Breda). Hofbauer has called attention to certain morphologic alterations, characterized by glycogen deprivation and fat infiltration of the liver cells, which he called pregnancy liver. It is questionable whether these observations should be regarded as evidence of hepatic lesions. However, the clinical investigations with several functional tests such as, carbohydrate assimilation or bilirubin excretion, suggest the presence of slight liver insufficiency in a considerable percentage of pregnant women, (Eufinger and Bader, Kaufman, Seitz). One is justified therefore, in believing that icterus occurring during pregnancy may be of hepatic origin. In addition, one must bear in mind that the influence of pregnancy upon the vegetative nervous system may cause a greater irritability of the smooth muscle fibers. This in turn may lead to spasms of the Oddi's constrictor muscle and possibly to inflammatory conditions of the biliary tract and finally jaundice. It might be mentioned, in passing, that the alterations of cholesterol metabolism in pregnancy play an important role in gall stone formation and thus indirectly in subsequent obstructive jaundice.

Icterus in extrauterine pregnancy has first been reported by Dick, and similar instances have been observed by other competent clinicians (Schottmüller) even though Horowitz and Kuttner did not find hyperbilirubinemia in 15 cases. The cause of the jaundice may be the resorption of bilirubin which has been formed within the hematoma. Michaelis believes that autohemolysins formed in the hemorrhage may cause intravascular blood destruction with increased bilirubin formation. In any event, increased blood destruction is responsible for the icterus; this is likewise suggested by the presence, in such cases, of hæmatin within the serum (Schottmüller, Bingold). The fact is of diagnostic importance.

Brief mention should be made of *icterus* occurring during menstruation. This was first described by Senator, but is today almost forgotten. Further investigations with the newer methods are desirable. Bergmann did not find bilirubinemia during menstruation.

Icterus neonatorum is of interest for the obstetrician as well as for the pediatrician. Since Hirsch and Yllpö simultaneously discovered that the umbilical blood of the newborn has an elevated bilirubin titer, icterus neonatorum has been re-

garded as a mere aggravation of a physiological condition. Yllpö regarded a relative insufficiency of the fetal liver as the cause for the bilirubinemia and jaundice. However, Aschoff's collaborators, Lepehne and Schultz have shown an excessive blood destruction by the reticulo-endothelial system within the first days of life. I have also seen conspicuous erythrophagocytosis within the spleen and liver in icteric newborn. Icterus neonatorum falls therefore into the group of over production icterus. Whether the liver is also insufficient to eliminate the excess bilirubin is of secondary importance. At all events, there is no morphologic evidence of liver pathology. The excessive hemoglobin destruction has recently been ably explained by investigations of Goldbloom and Gottlieb and of Anselmino and Hoffman. They have shown that the intrauterine fetal organism exists under conditions of extreme oxygen dearth, which condition could never be tolerated in extrauterine The oxygen tension of the fetus corresponds to that at an altitude of 10,000 meters. The same compensatory phenomena are called into play which take place in life at high altitudes and which have been investigated by the British Mount Everest Expedition of 1924. Elevation of the red cell count and the hemoglobin and the increase of the total blood volume are of the greatest significance for the problem of icterus of the newborn. With birth, all those compensatory measures become superfluous and the adaptation to the lack of oxygen suddenly changes for an acclimatization to the normal conditions of extrauterine life. About 30 g. of hemoglobin are destroyed and transformed into bilirubin. While these investigations have fully explained the reason for the postnatal increase of the bilirubinemia which leads to the visible icterus, the physiologic bilirubinemia of the newborn at birth is not accounted for. Here Schick's hypothesis gives a satisfactory explanation. According to this author a considerable quantity of maternal blood is to be destroyed within the placenta during intrauterine life in order to supply the fetus with the material, especially, iron, from which to form its own hemoglobin. The pigment factor thus liberated furnishes the amount of bilirubin circulating in the newborn at birth. According to these considerations icterus neonatorum hardly be regarded as a morbid condition. Intercurrent diseases or the debility of the premature infant are usually responsible for death.

Those cases in which icterus is the leading symptom of a serious disorder of the infant are quite different. These instances have been called icterus gravis of the newborn. At autopsy, it is not uncommon to find a sepsis originating from an infection of the umbilicus; rarely congenital syphilitic hepatitis is responsible for jaundice. However, other destructive lesions, and in rare cases, even acute yellow atrophy have been observed, (Klemperer, Lit.). An umbilical infection

which does not cause general sepsis and early death may in due time produce severe parenchymal damage causing icterus Apart from such cases of acterus, due to hepatic damage there are cases of severe, occasionally, congenital icterus in which a blood dyscrisin seems to be responsible Such cases, characterized by an excessive number of nucleated red cells have been termed erythro blastosis of the newborn They may be com plicated by congenital hydrops and icterus of the The investigation of three such cases has caused me to regard them as the result of a disturbance in the coordinate development of the blood-forming organs The icterus must be considered as an over production icterus, masmuch as there are no liver lesions. These eases occur repeatedly in one family and most of them are fatal

Icterus syphiliticus and salvarsan icterus are of great interest for the dermatologist. It has long been known that the treponema of syphilis has an obvious tendency to cause liver damage This holds, not only for the characteristic hepatic lesions of the tertiary stage, but also for dis orders of the liver in the early phase of syphilis The occurrence of acute yellow atrophy in the secondary stage has been described by Lebert shortly after the discovery of the disease by The mild icterus in the secondary Rokitansky stage, first observed by French and German physicians in the latter part of the nineteenth century found only speculative interpretations (Wile, Lit) because anatomical investigations in such instances were lacking. Eppinger was the first who studied such a case in a man who had committed suicide. At necropsy he found degenerative and destructive liver cell lesions similar to those observed in some cases of the so called "catarrhal icterus" Clinical observations likewise indicate that the icterus in this period is due to a func-tional disturbance of the liver The problem of icteriis in the early stages became more complicated after the introduction of arsphenamine One had to keep in mind that this drug may also be responsible for the liver damage The problem of arsphenumine jaundice was one of the most controversal points in dermitology The present concept may be best summarized in the following way (Gjessing) Icterus which becomes manifest during or shortly after the treatment (Icterus paratherapeuticus of Milian) may be divided into-I Icterus intertherapenticus and II Icterus post therapeuticus The former is subdivided into Icterus (a) due to Jarisch-Heraheimer reaction, i e, due to an aggravation of a latent syphilitic hepatic lesion (b) Biotropic icterus caused by a stimulation of a previously existing non specific disorder of the liver or biliary trace (c) Toxic icterus result of an overdose, idiosyncrasy or poisonous preparations Intercurrent acterus

Icterus post therapeuticus may be divided

into (a) Icterus syphiliticus crused by a local (Hepato) recurrence ind in (b) accidental intereurrent icterus. The existence of a late arsphenamine icterus is problematic. The practical conclusions in regard to therapy are logical. The liver function should be watched during the course of treatment (Dixon et al) and if icterus should arise the dring used should be stopped and replaced by another one, since one is unable to decide whether the jaundice is due to a syphilitic liver lesson or due to biotropism for the first dring used. In post-therapeutic icterus arsphenamine treatment can be recommended because it is chiefly due to syphilis and requires intense therapy.

In the following resume of the different chinical forms of acterus emphasis will be placed upon one element of the pathogenesis which as has been mentioned previously as of utmost importance for the practitioner in medicine—the question of the presence or absence of lesions of the polygonal hepatic cells

In reviewing a large series of cases of icterus as they are encountered within a period of several years in an active hospital, difficulties arise in the classification of the actual pathogenesis of a considerable proportion is generally simple to determine the cause of icterus in cases of obstruction of the larger bile ducts, in severe destructive lesions of the hepatie parenchying as in acute yellow atrophy in its various states or in Jellow fever, and even in hemolytic jaundice of the constitutional type or in pernicious anemia and malarm However, the question of the patho genesis becomes very complicated in leterus occurring in the course of infectious diseases such as lobar pneumonia, septicemia, Weil's disease, in jaundice of cardiacs, in cirrhosis of the liver and particularly in the so called catarrhal jaundice

Among the cruses of obstructive trundice. occlusion of the bilinry ducts by stones or neoplasm is of prime importance. Among the more uncommon causes I mention, stenosis of the ampulla of Vater by neoplasm duodenal ulcers, juxtapapillar diverticulæ (Bengolea, Greder, Th Rosenthal) or permanent spasms of the muscle of Oddi (Pavel) The obstruc tion is usually complete in the malignancies, but incomplete in the greater number of cases of stone (Weir) Among the neoplasms, earemoma of the pancreas is more frequent than of the larger hiliary ducts Carcinoma of the ampulla of Vater occasionally causes intermittent jaundice (Stakevitch Carnot) differential diagnosis from stone occlusion occult blood or tumor cells within the duo denal contents should be looked for Jaundice in primary liver carcinoma may be due to pressure upon the common hepatic duct, or to alterations of the cirrhotic liver in which they

generally arise. Metastatic neoplasms cause icterus only when they obstruct the outflow of the bile. The presence of an ecchinoccus cyst (Castex et al), gummata, inflammatory or hyperplastic lymph glands, such as in tuberculosis, Hodgkin's disease or leukemia may produce icterus, but such an occurrence is rare. Chronic pancreatitis as a cause of obstructive jaundice is frequently mentioned by surgeons, but is rarely found at necropsy.

Inflammation of the biliary passages as a frequent source of obstructive jaundice is a moot question. Cholangitis may be present at various levels in the biliary passages, extending to the larger ducts from an infection from the duodenal lumen or to the finer radicals from the blood stream. (Ascending or descending cholangitis or cholangiolitis.) Ascending cholangitis is frequently the result of a primary obstruction in the bile passages, which makes it difficult to evaluate its relative significance in the causation of icterus. The persistence of jaundice after removing the obstructing stone is often regarded as the result of a persisting cholangitis. However, it must be borne in mind that prolonged biliary stasis can produce hepatic lesions which may be responsible for the icterus, while at this stage the cholangitis is only of secondary importance. The French school of Fiessinger and Albot, Benard and Caroli have always emphasized the existence of liver cell damage in cholelithiasis. have described minute alterations of the mitochondria, while Heyd, Killian and Mac-Neal in this country have paid chief attention to inflammatory changes in the framework of the liver. Naunyn and his school have stoutly stressed the importance of bile duct infections as primary cause of icterus. Moreover, Schottmüller, Ümber and others have repeatedly emphasized the significance of the hæmatogenous infection of the finer bile radicals. Among pathologists, Frænkel and Siegmund have demonstrated such lesions in cases of icterus.

Of considerable interest are also instances of chronic remitting jaundice, which have been called "cholangitis lentea." The conspicuous splenomegaly in such instances may lead to an erroneous diagnosis of hypertrophic cirrhosis. At post-mortem examination of two such cases, I found a diffuse inflammation of the small intrahepatic and precapillary bile canaliculi with more or less extensive hepatic fibrosis. The recognition of the pathogenesis of these cases is of importance because this knowledge alone will determine a rational therapy.

The foregoing discussion demonstrates the significance, as well as difficulties of the differential diagnosis between cholangitis and hepatic lesions in icterus. However, clinical observation supported by a study of the liver function may clarify these cases.

In acute yellow atrophy there can hardly be a question about the severe parenchymal destruction being responsible for the jaundice. The etiology of this most serious liver disorder is still obscure. The occurrence during pregnancy and in syphilis has already been mentioned. Cases have also been observed during or following severe bacterial infections and subsequent to intoxications. Public health officers may be interested in the occurrence of such cases among workers in the artificial pearl and in the aeroplane industry due to inhalation of tetracholorethane used in the manufacturing process (Fiessinger et al). Reports of cases of acute yellow atrophy following the use of atophan or cinchophen have aroused great interest in the medical profession in recent years. Because some cases of jaundice have been observed after small doses while in many instances very large doses over a long period have been tolerated without any sequelæ, it is safe to assume that an individual idiosyncrasy to atophan was responsible in the cases observed. Dr. Fishberg and I have been unable to reproduce hepatic lesions in rabbits even with excessive doses. The progress of the liver atrophy is not always acute; many cases show a prolonged course with persistent Conspicuous parenchymal regeneration is characteristic of these chronic cases and this leads to the picture of coarse nodular (Marchand) or toxic cirrhosis (Mallory).

Mention only shall be made of the severe liver lesions in phosphorus and mushroom poisoning, which are anatomically different from acute yellow atrophy (Klemperer).

The clinical and anatomic observations in constitutional hemolytic anemia, pernicious anemia, malaria and the sporadic incidents after transfusion of incompatible blood leave no doubt that the icterus is primarily due to an elevated bilirubin formation resulting from excessive blood destruction. Whether there is an additional relative or absolute insufficiency on the part of the liver to eliminate the bilirubin is of minor significance. These cases are placed into the group of over-production The increased blood destruction is due to an abnormal condition of the red cells and is not due to any primary hyperfunction of the reticuloendothelial system. Because of its unique architecture, the spleen is specially capable of intercepting and destroying red cells, and the removal of this organ may exert a favorable influence because of the elimination of the excessive destruction of the pathologic erythrocytes. In a number of cases, however, splenectomy is unsuccessful (Freund).

The interpretation of the icterus as it occurs in lobar pneumonia, septicemia, Weil's disease, cardiac decompensation and circhosis proves to be more complicated.

Jaundice in lobar pneumonia is not frequent. Dr. F. King has compiled 635 cases observed within the last 6 years, at Mt. Sinai Hospital; 42 (6.6%) of these showed ieterus. A moderate bilirubinemia without clinical jaundice occurs in every case according to Eltou. The prognostic significance of jaundice in pneumonia is controversial. Elton regards it as a favnrable event. According to Banti and our experience the prognosis is poor. Of 42 cases with ieterus, 21 (50%) died, while the total mortality varied in different years between 9.6 to 22.8%.

The cause of icterus in pneumonia is not vet fully understood. The older clinicians maintained that icterus occurs chiefly in right sided pneumonia and believed it to be due to bile stasis caused by the arrest of the diaphragmatic motion. It may be mentioned that Petroff only recently demonstrated that a more active flow of bile in rabbits occurs with deep respiration. This mechanical explanation. however, has been discarded. Banti believed that the hemolytic action of the various strains of pneumococci was responsible and considered the jaundice as a hyperproduction form of icterus. Eppinger observed two cases with abundant iron deposits in the lung and suggested that bilirubin may be formed from the intrapulmonic destruction of the hemorrhagic exudate and its resorption may eause icterus. Repeated intratracheal injection of blood in rabbits causes, according to Mangeri, an elevation of the serum bilirubin. However, personal investigation of the lungs in lobar pneumonia with and without icterus did not reveal a conspicuous hemosiderosis as Eppinger has described. It therefore remains doubtful whether icterus in pneumonia should be classified as an over-production type. Degenerative alterations of the liver cells have been observed-Rich believes these to be due to anoxemia. However, it is difficult to accept such lesions as the sole cause of icterus, because similar changes are observed without the existence of jaundice. Rich therefore claims that the combination of liver cell damage together with increased bilirubin formation is responsible for the icterus. Likewise a cautious viewpoint must prevail in regard to observations of cholangiolitis, although I have constantly found leucocytic infiltrations around and single leucocytes within the precapillary biliary canaliculi in every case of pneumonia icterus while they were inconstant in other cases of lobar pneumonia.

Most probably a similar situation prevails in icterus occurring in septicemia. The occasional observations of extensive liver necrosis in such instances, suggests a hepatic origin; however, one must not neglect the fact that identical lesions occur without icterus and that jaundice may have existed without any hepatic

lesion to be found at autopsy. One cannot conceal the fact that we do not yet know the type of liver cell alteration which is inevitably responsible for jaundice. Caution must also be recommended in the evaluation of cholangitis and of the presence of even conspicuous erythrophagocytosis. It is possible that only a combination of all these factors causes icterus.

It is not clear whether the icterus in Weil's disease is caused by liver changes as claimed by the French school or by increased blood destruction. In a considerable number of cases characteristic liver lesions are present, among which hypertrophy of the liver cells, frequent mitoses and occasional necrobiosis are most prominent. There is also a conspicuous erythrophagocytosis within the spleen which suggests an increased bilirubin formation. Both of these factors may account for the development of icterus.

Icterus in cardiac decompensation has formerly been considered as the result of pressure by the dilated sinusoids upon the bile capil-Oertel has demonstrated extensive hepatic necrosis in cases of cardiac icterus. believed that increased blood Eppinger | destruction within the congested lung chiefly after infarction causes increased bilirubin formation. Keefer and Resnik have experimentally shown that anoxemia impairs the elimination of bilirubin by the liver. Accordingly, Rich regards icterus in cardiac decompensation as the result of increased bilirubin formation and impaired climination. However, in these cases a discrepancy between the intensity of the jaundice and the degree of the hepatic lesions is not uncommon (Kugel and Lichtman). This indicates that the above explanations probably do not account for all the factors to which the jaundice may be attributed.

The explanation of icterus in liver cirrhosis is involved because its frequency and nature varies in the different forms of this condition. It is impossible to enter in a discussion of eirrhosis at this time. For convenience and in agreement with the point of view formulated at the last international Congress of Geographical Pathology, I shall distinguish three types. 1. Lænuce's cirrhosis; 2. Biliary cirrhosis; 3. Toxic cirrhosis. The differentiation between hypertrophic and atrophic cirrhosis has been abandoned. While icterus prevails in biliary and toxic cirrhosis, it is not conspicuous in the first type. Obstruction of the bile channels causes the icterus in biliary cirrhosis, while the severe damage of the liver parenchyma is responsible in toxic cirrhosis. In Lænnec's cirrhosis the cause of jaundice is not a single factor. Severe icterus develops occasionally as a terminal event. At times, there are repeated attacks (Fiessinger

et al 1932). The clinical investigation of such cases shows that other functions of the liver are also seriously impaired during these attacks and the anatomic histologic investigations reveal severe parenchymal lesions occasionally with extensive cell necrosis. (Bache and Klemperer.) Apart from a hepatic pathogenesis, jaundice may be the result of such a factor which simultaneously causes a sclerosis of the liver and a conspicuous blood destruction. Roessle designates such forms as "angiohæmatotoxic cirrhosis." The mild jaundice of certain cases may accordingly be explained as overproduction jaundice and the occasional severe attacks correspond to the blood crises of hemolytic anemias.

In the final discussion of the problem of the so-called catarrhal jaundice, I shall be very brief. I am well aware that this diagnosis neither embraces one single group of similar etiology and pathogenesis nor that a catarrhal inflammation of the biliary tract is the sole cause. If I still continue to use the term I do it is a matter of convenience and because of the lack of a better name, but at any event, will qualify it by adding the term "so-called." Every practitioner of medicine knows what is meant by the term which is used to designate the icterus usually occurring in young people, characterised by a sudden onset and a duration of several weeks which always results in apparent perfect recovery. If one can rule out cholelithiasis because of the clinical symptoms and the negative x-ray examination, the diagnosis of "so-called" catarrhal jaundice is justified. Other terms recommended such as simple icterus are of no advantage, infectious or toxic icterus is too specific and limited, while the term afebrile acute icterus (Garnier) is not correct because fever is present in some cases of this group. One may, therefore, continue the use of the qualified term though the name does not fully conform with the pathogenesis.

Clinical and histologic studies have shown that hepatic lesions are responsible for many of these cases (Klemperer et al Lit). But similar considerations indicate that another group of identical symptomatology is due to ascending or descending cholangiolitis and not essentially to liver damage.

SIGNIFICANCE OF LIVER FUNCTION FROM THE SURGEON'S STANDPOINT

Read as part of the Symposium on Some Disorders of Liver Function at the Annual Meeting of the Medical Society of the State of New York at New York City April 5 1933

By CHAS GORDON HEYD, MD, NEW YORK, N Y

THE liver is interposed between the portal and systemic circulation The blood from practically the entire viscera of the abdomen passes through the liver and there is a very intimate lymphatic association between the liver and gall bladder and pancreas The liver reacts to influences such as infection and the by products of improper gastrointestinal digestion Deleterious material may reach the liver by way of the vascular channels or through the lymphatic routes, in addition to direct exposure by continuity of tissue liver thus possesses a unique influence as a protective inechanism and in turn suffers in varying degrees from any type of abdominal infection

To a remarkable degree the liver has the ability to regenerate by hyperplasia but it does not exhibit the work hypertrophy plienomenon from over-function In fact, the degree of liver regeneration is so great that as much as 70 per cent of the liver of a rat may be removed with complete regeneration in four to six weeks, and it has been demonstrated that after 85 per cent of the liver has been removed surgically, it can still function in a comparatively normal manner Material losses of liver substance however, such as occur in progressive, proliferative fibrous hepatitis, markedly impair its detoxifying function and its ability to maintain blood sugar level as well as the loss of its deamonization function in protein metabolism

The hepatic changes roughly classified under the loose designation of "hepatitis" may be recognized at operation. The degree of hepatitis and loss of liver function have a far reaching effect upon mortality statistics of gall.

bladder surgery The microscopic cyidence of liver disease, secondary to abdominal infection, is confirmed by histological examination of sections and it has seemed possible to suggest that the explanation for the so called "liver deaths' after a laparotomy are due primarily to liver insufficiency or liver dysfunction The anticipation and prevention of a possible failure in liver function before opera tion is the patient's best safeguard for surgery in that adequate and rational pre operative treatment may be undertaken The liver regulates, quantitatively, the amount of carbohydrate that is furnished to the body cells under the diverse conditions of carbohydrate intake and bodily activity Mann² has demonstrated that the normal blood sugar level is maintained by the liver and his experimental work has demonstrated that the liver exercises its function in regard to protein metabolism in three ways I deamonization, urea forma tion, and 3 uric acid destruction

If the protein metabolic function of the liver is inhibited or diminished there is the progressive mability for diamidization of protein and urea is produced in lessened amount. It follows therefore that any type of trauma, such as surgical intervention, infection, loss of heat production by products of portal obstruction, and anesthesia, may temporarily or permanently impair in varying degrees one or all of the functions of the liver. It follows therefore that depending upon the functional integrity of the liver the patient after operation will avoid post-operative complications of diverse types and varying degrees of severity

Early in 19223 it became apparent in a study of our post-operative results after cholecys-

tectomy that there occurred, infrequently to be sure, but nevertheless from time to time, three clinical states that intervened after operation on the biliary tract and almost invariably resulted in death. The character of these mortalities led us to believe that they were the direct result of a disturbance in the protective function, ordinarily exercised by the liver4. We began to study these cases with greater care both from the clinical and biochemical standpoint, as well as from necropsy examinations. The deaths that follow abdominal surgery are in general readily explicable, both from the point of view of the conditions found at operation, the type of operation performed, and the pre-operative condition of the patient. One ordinarily expects when a mortality follows a laparotomy that it may be ascribed to shock, hemorrhage. gastric dilatation, development of peritonitis, emboli, pneumonia and cardiac failure. We designated the unusual mortalities as deaths" and classified them into three types. The portraiture of each type may be made by giving the history of a typical example.

Type I. A woman, aged 37 years, entered the New York Post-Graduate Hospital complaining of gas after eating and occasional pain in the right upper quadrant. There had been one attack of pain requiring a hypodermic of morphine. On examination the blood count was normal, the Wassermann test was negative and a phenolsulphonphthalein test for kidney function was normal. The patient was operated on at 9 o'clock in the morning. A simple cholecystectomy was performed, the common duct was not involved, and nothing noteworthy was found in the pancreas or in the remainder of the abdomen. The liver, however, showed a slight enlargement. The edges were crenated, the consistency was leathery. From the area of the gall bladder region was a white, rosette-like tissue, extending well over the dome and inferior surfaces of the right lobe of the liver. The patient had a simple ether anesthesia. The immediate postoperative reaction was normal. However, the patient did not completely come out from the anesthetic and was not awake by 3 o'clock in the afternoon. At the end of 12 hours the patient was decidedly lethargic or semicomatose and there was a gradual ascent in temperature, successively through 102, 103, 104, 105 and 106, F. The pulse rate and respiration paralleled the temperature rise. The chemical examination of the blood showed a normal icteric index and a gradual ascending scale of urea-nitrogen. Clinical examination of the lungs gave no evidence of pneumonia. The patient died at the end of 36 hours.

Type II. A form of liver death much more

infrequent than Type I has occurred in patients who have had a previous cholecystectomy and rarely a drainage of the common duct. The patient is jaundiced, and the secondary operation consists of a choledochotomy, with tube drainage. For the first few days after operation the post-operative course is normal and satisfactory. Then there is a distinct change in the character of the drainage. The biliary discharge becomes less and less in amount and more watery in consistency. In spite of the constantly dimishing jaundice, as shown by the decreasing icteric index, the patient becomes delirious; there is marked cerebral excitation, subsultus tendinum and carphology occur and finally stupor and coma. There is no clinical evidence of intra-abdominal hemorrhage or infection, yet in spite of a diminishing jaundice, coma develops, which in all of its clinical manifestations is similar to that which occurs in a terminal cholemia. By reason of the marked cerebro-spinal irritation, spinal puncture has been made and practically normal fluid obtained, with a slight globulin reaction and cell count of 9 or 10 cells per cubic millimeter.

Type III occurs much less frequently than either Type I or Type II and apparently is more amenable to treatment. These patients have diseases of the common duct, and pancreatitis, do not have jaundice, and for the first 24 to 36 hours after a choledochotomy with tube drainage have an apparently normal post-operative course. Then the pulse rate becomes markedly accelerated. patient becomes markedly prostrated, with a fall in blood pressure and a cessation of urinary secretion, and exhibits cold, clammy, moist extremities. The abdomen is without any clinical evidence of infection, hemorrhage or any unusual post-operative abdominal con-A negative gastric lavage demonstrates an empty stomach and no gastric dilatation. One is impressed that while the clinical condition herein presented is very similar to shock it occurs from 24 to 36 hours after the operation and seems to be a complete vasomotor collapse from an overwhelming intoxication. Transfusion and repeated infusions of physiologic solution of sodium chloride with 10 per cent. dextrose are usually sufficient to save the patient.

It is a matter of physiological importance that the liver with its tremendous bulk and unique blood supply has only three types of cells—the polygonal liver cells, the cuboidal cells of the bile canaliculi and the reticular cells of Kupffer. By reason of the diverse metabolic functions of the liver, research workers, biochemists and clinicians have promulgated various tests for liver function

in which the attempt is made to detect some specific failure of liver function. According to Killians the tests of liver function are grouped as follows: (a) tests of the exerctory functhe urine and dye tests such as phenoltetrachlorphthalein, bromsulphthalein, etc.: (b) tests of the functions played by the liver in carboliydrate metabolism-galactose tolcrance: (3) tests of the functions of the liver in the analysis and synthesis of the intermediate products of protein metabolism-nitrogen partition of the blood and of the urine. With the exception of the galactose tests, and the dye tests of liver functions, the chemical analysis of blood and urine even in the every day routine work of the laboratory, may be made sufficiently comprehensive to include determination which will yield valuable data concerning liver function.

Of outstanding importance in the pre-operative and post-operative protection of gall bladder cases is an appreciation of the importance water-salt enterohepatic circulation (a) and (b) the enterohepatic circulation of bile pigments. The water-salt circulation is of far reaching importance and it is an interesting atavistic remembrance to the fact that all life originally began in the sea. Human life may be said to depend upon an adequate and precise adjustment of the water-salt balance. Rowntree, states that the total of all secretions poured into the intestinal tract varies from 7500 to 10,000 c.c., an amount of fluid more than twice the total blood volume. Orr' has succinctly demonstrated the outstanding of dehydration, hypochloremia and acid-base balance in pre-operative and post-operative treatment, and indicates that while an animal may lose 40 per cent. of its body weight in glycogen, fat and protein without death, a water loss of 10 per cent. is associated with serious complication, while a loss of 20 to 22 per cent. of water invariably brings about death. Any liver or gall bladder condition that is characterized by persistent vomiting, brings about a marked hypochloremia and the important indication when vomiting is present is to provide a proper amount of chlorides by the introduction of 500 e.c. of 5 per cent. solution of sodium chloride intravenously, or if a more rapidly acting salt therapy seems necessary 20 c.c. of 10 per cent. solution of sodium chloride intravenously.

The enterohepatic circulation of bile pigments is based upon the fact that when bile is delivered into the intestinal tract the bilirubin is converted into hydrobilirubin. The latter, by the activity of intestinal bacteria, is changed into stercobilin and urobilin. The urobilin is in a large measure reabsorbed by

the intestinal veins of the portal system and delivered to the liver cells. Some of this urobilin is excreted with the bile so that we have a constant urobilin cycle or an hepato-enterohepatic circulation. (Chart 1.) Under normal conditions no urobilin can be determined in the urine. When urobilin reaches 1 milligram in 100 cubic centimeters, or 1 in 100,000 it may be detected in the urine by adequate tests. For a normal enterohepatic circulation it is necessary to have intact liver cells, for in the presence of normal liver cells the urobilin does not escape into the systemic circulation. It is obvious that in the presence of complete obstructive jaundice there can be no reabsorption of urobilin from the intestine and hence probilin does not appear in the urine. If, however, there is an incomplete obstruction, which will permit of the delivery of some bile into the intestinal tract, then the presence of any slight degree of functional disturbance of the liver cells will permit urobilin to escape into the systemic circulation and its subsequent appearance in the urine. If the liver cells are injured, however, with or without obstruction,

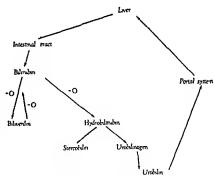

CHART 1. Enterohepatic circulation of bile pigments.

there is a delivery of urobilin into the systemic circulation. MacMaster and Rous¹o have drawn attention to minute quantities of urobilin that may be found even in the presence of complete obstruction. The mechanism for this presupposes that in conditions of chronic icterus there is an elimination of bilirubin into the intestinal tract by the systemic eirculation, and this bilirubin is clanged to urobilin and is reabsorbed by the portal system, and, in the presence of injury to the liver cells, is delivered into the blood stream and later appears in the urine.

We have relied almost solely on the following tests: 1. the icteric index; 2. the Van den Bergh, and occasionally the Fouchet; 3. the

galactose test, and 4. routine chemical analysis of the blood. The most effective test in our opinion is the icteric index and the occasional error that occurs from extraneous pigmentscarotin (carrots, oranges and eggs)-can be very easily avoided by a pre-operative diet. In our opinion, there are no means whereby the clinician can estimate the vital integrity of the liver cells or their ability to withstand The clinical estimation of surgical trauma. the patient's resistance, aided by serial icteric determinations, is in our opinion, the most valuable of all means of a pre-operative estimation of the expected mortality possibilities. It is our rule to have these patients enter the hospital two days before operation, and during this time we attempt to accomplish two specific purposes: 1. a complete and full water balance and 2. to increase the reserve of glycogen in the liver11. The routine laboratory tests of urine are carried out, together with the routine chemical analysis of the blood. patient is not given cathartics previous to operation, but each day the lower bowel is evacuated by the use of an enema. The patient is encouraged to drink freely of fluids, particularly those containing sugar, such as gingerale, lemonade, etc. At least 1500 c.c.—2000 c.c. of tap water is given by rectum, containing 10 per cent glucose and partitioned into three periods of eight hours. The diet is high caloric, carbohydrate, irrespective as to the weight of the individual, and practically no protein intake permitted. The carbon dioxide combining power determinations are of the utmost important as they indicate whether we are dealing with varying conditions of alkalosis or If the carbon dioxide combining acidosis. power moves to the right, the administration of glucose is always advisable, either by mouth, rectum or intravenously. Glucose maintains, in a large measure, the heat requirements of the body. It is also one of the most effective means of relieving dehydration. By reason of its readily oxidizable qualities it acts as a buffer and prevents the destruction of protein and therefore is an antiketogenic agent. Cases of alkolosis are usually associated with a marked degree of ketogenesis and therefore glucose has an additional value if this condition is present.

In patients with a jaundice we are confronted with an additional element of danger. Serial icteric determinations will indicate if the jaundice is stationary, arrested, or advancing. A Van den Bergh test in the beginning is possibly suggestive as to the etiological factor in the production of the jaundice. The preoperative diagnosis as to the causal factor in jaundice is of the utmost importance. An individual without jaundice, so far as surgical intervention is concerned, is an altogether distinct class in regard to operability and safety from a patient with an obstructive jaundice or a patient with both obstructive and intrahepatic jaundice. In the patient with jaundice, bleeding and coagulation time must in all cases be done and a clotting time that exceeds eight minutes, carries with it the possibility of post-operative hemorrhage. It is our feeling that blood transfusion before operation is of infinitely more value than blood transfusion after operation or when bleeding has already started. The suggestion of Walters of the intravenous administration of 5 c.c. of 10 per cent solution of chloride calcium is of the utmost value both before and after operation.

In conclusion, mention should be made of the contribution of Vogel¹² and the possibility of retained arsenic being a factor in liver degeneration and which even in mild cases is accompanied by some degree of jaundice. Arsenic is found in many individuals without any discoverable cause and without giving rise to symptoms. However, in a series reported by this author an excess of arsenic was found in the secretions in 34 out of 40 cases suffering from jaundice and in 9 of the 34 cases in which arsenic and jaundice occurred simultaneously, death resulted and in 4 of these cases death promptly followed an operation on the biliary tract.

PERSONAL IMPRESSIONS IN THE TREATMENT OF A FEW OF THE COMMONER INVETERATE DISEASES OF THE SKIN

By FRED WISE, MD, NEW YORK, N Y.

Read before the Section on Dermatology and Syphilology, at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933

In adopting the suggestion offered by our Chairman, that I submit to you some of my impressions in the treatment of certain common dermatoses, I am properly grateful for the latitude which he has permitted me, in the consideration of the broad subject embraced in the title

A fact to be emphasized at the very beginning is this that I am fully aware of the wide gaps which bridge "impressions and facts," "impressions and statistics' and "impressions and proved clinical and laboratory data". With this awareness comparatively an easy one; as the saying goes, I have been saved a lot of work. You are not to hear a word about "References to the Literature," either foreign or domestic, nor about my case records, either public or private.

Rather than go into unnecessary details regarding certain dermatoses with which all of you are familiar. I propose to discuss the treatment of a limited number of affections from a broad, general viewpoint. Those which I have selected are the following acides sycosis barbae, psoriasis, chronic urticaria, disseminate neurodermatitis, chronic recurrent herpes simpley, and the various eruptions due to, and associated with, ringworm and monitia infections. I designate these as examples of some of the commoner inveterate dermatoses.

I believe that one of the most important factors relating to the treatment of chronic persistent dermatoses is the proper and adequate employment of topical remedies. The difficulties and disappointments encountered in the management of ambulatory patients and those treated at their homes, lies, in great part, in their mability -for many obvious reasons-to carry out our instructions with regard to external applications In patients with eruptions on the face, neck and hands, this restrictive element is of considerable significance in attempts to evaluate the effects of certain remedies, not to mention the unsatisfactory results to be expected from topical applications which are used only during the patient's hours of sleep mstead of a twenty-four hour It is only the exceptional patient who will appear in public with face and hands covered with lotions, salves or bandages vividly reminded of attempts to treat ambulatory patients with sycosis barbae by means of local applications of brilliant green. It is the exception, also, rather than the rule, to encounter patients afflicted with widespread, generalized or disseminated eruptions who obtain treatments

which we consider to be efficacious, in their own homes. Every effort should be made to hospitalize such patients.

Unfortunately, it is not an easy matter to persuade the majority of them—even those in good eigenmatenes—to enter a hospital or sanitarium On many occasions have I been strongly tempted to quote to the obstinate protestor the words used by a truculent Roman general in addressing his army, he said "Soldiers, I have often heard, that he is the first man, in point of abilities, who, of himself, forms good counsels, that the next, is he who submits to good advice, and that he who neither can himself form good counsels, nor knows how to comply with those of another, is of the very lowest capacity"

The advantages of hospitalization as compared with ambulatory and home treatment need not be enumerated, being in themselves so self-evident Nevertheless, mention should be made of certain important features not directly connected with the mechanical aspects of the management of the patient's skin disease, for example, the availability of hospital facilities in regard to laboratory and a-ray investigations, the facility with which such patients may undergo examinations by the family doctor or the dentist, or by other specialists called in consultation, the opportunities to observe changes and reactions produced by various medicaments and internal or parenteral remedies, and to note the results of skin tests and the patient's susceptibilities and idiosyncrasies

Aside from these advantages, we must take into account the benefits derived from rest in bed, change of environment and so forth. In patients whose emptions are suspected to be of allergic or sensitization type removal from home, office factory or shop is often almost a sine quanon in bringing about relief or circ

In the treatment and general management of the group of common diseases under discussion. the dermatologist naturally has ample opportunities to arrive at an appraisal of the value of many remedies The remedies which in my hands have proved the most useful and have stood the test of time, are those with which everybody is These are 1-rays and-in a much more restricted sense-ultraviolet light, of external medicaments, the ancient remedies-astringents, reducing agents, keratolytics, keratoplastics and so forth-still serve their purposes when and where judiciously used, so that my prescriptions of today vary but little from those of my younger days Their ingredients comprise now, as they did then, mercury, sulpling, resorcin,

salicylic acid, chrysarobin, tar, bismuth, zinc and so forth, in ointments and pastes; and boric acid, Burow's solution, solutions of potassium permanganate, iodine, nitrate of silver, shake mixtures of calamine, zinc, magnesium, tale, starch and so forth, in lotions, wet dressings and baths.

We all know that a great variety of older remedies disguised by new names, as well as many new synthetic and other types of drugs and chemicals are constantly flooding the market, and are often urgently recommended—not by manufacturers alone but by physicians as well-for many obstinate and recurrent forms of eruption. In refraining from specific mention of these, I do so, not because I am unaware of their existence or of their alleged value, but because I have had so little personal experience with most of them, that I have not been enabled to gain even a fairly good insight of their worth. To cite a few examples, I have been informed that pustular acne responds exceptionally well to intravenous injections of calcium chloride, and I hope myself to verify this observation in the near future. have read reports of good results obtained from the use of spleen extract for the relief of itching in various dermatoses, but have not yet had the opportunity to use the extract myself. The same statement applies to histamine, salts of silica and many other chemical substances.

On the other hand, I have given a number of remedies what I regard to be a thorough trial, and have, more often than not, been sadly disappointed in them. For instance, I have personally treated a group of patients with sycosis barbae by means of turpentine injections, intramuscularly, without noting the slightest benefit; perhaps my technique was at fault, or the patients were not favorable subjects, or my diagnoses were false, but surely the turpentine found a resting place in their buttocks.

The so-called "dramatic" effects of the arsenicals in syphilis, the gold salts in lupus erythematosus, the adrenalin injection in urticaria, are sadly lacking, to say the least, in the salts of thiosulphate, in the various calcium combinations employed intravenously, in the much-vaunted bromide salt preparations and in many other remedies recommended for use by mouth and parenterally. I do not imply that they are of no value, but I am sure that we must be careful not to overestimate them, in their application to the group of dermatoses with which I am dealing. At any rate, I have found their appraisal to be very difficult and I must admit that my attitude toward them is strongly tinged with a philosophic skepticism.

On the other hand, certain remedies have proved their worth beyond question. Of these few, I have found arsenic capable of exerting a powerful influence upon chronic psoriasis, eczemas, urticaria, acne and selected cases of neuro-

dermatitis. During the many years in which I have used arsenic as an adjuvant in the treatment of these and many other ailments, no instance has been called to my attention which caused me to regret the employment of that drug in any individual; as a matter of fact, I do not believe that any of the patients under my personal control have suffered as the result of arsenic medication; many have, to the contrary, been benefited by it.

I believe that arsenic is best administered by subcutaneous injections, in the form of a two to four percent solution or sodium arsenate, and—provided no contraindications exist—it should be given in quantities approximating the "dosis tolerata." When injections cannot be used, I prescribe the Asiatic pill, consisting of arsenious acid, black pepper and gum tragacanth, in ascend-

ing doses of arsenic.

In a relatively small proportion of patients with pruritus, eczema, psoriasis, disseminate neurodermatitis and urticaria, I have learned that autogenous blood injections seem to be beneficial. Whether or not the effect be partly or wholly psychic, or whether suggestion plays no role whatever in the procedure, is beside the point. Suffice it to say here that I believe that autohaemotherapy should, in selected cases, be tried, when simpler remedies have failed. It has the advantage, over other non-specific measures, of being practically painless and apparently harmless.

Acne Vulgaris

Acne manifesting itself in the form of a few scattered indurated papules on the chin of a middle-aged woman, is often far more resistant to orthodox methods of treatment than a severe and widespread papulo-pustular eruption in a healthy adolescent. It is unnecessary for me to dwell on the general treatment of acne patients, except to stress that the ingestion of iodine in table salt might be a possible factor in the persistence or recurrence of the lesions in certain patients; and to mention the role of iodine metabolism in its relation to thyroid gland imbalance, possibly associated, in the etiology of the affection, with puberty and adolescence.

I regard x-ray therapy to be the best and most reliable means of curing the eruption, and hold ultraviolet light therapy in reserve as a good adjuvant. In inveterate cases, more especially in those in whom a certain cumulative total dose of x-rays has been administered without accomplishing a cure, I advise the patient to use hot wet dressings of diluted Vleminckx's solution, with almost uniformly good results. (This solution of sublimed sulphur, 250.0, quicklime, 150.0 and water, 2500.0, boiled down to 1500.0, should be used freshly prepared and in solutions of various percentages, of sufficient strength to cause a moderate degree of scaling of the affected parts.) I administer arsenic alone, or arsenic combined

with iron in rebellious cases. A certain proportion of such cases have responded favorably, in my hands, to stock acne vaccines, provided they were administered over long periods. I have had no personal experience with bacteriophage and cannot recall conclusive results from endocrine therapy, even in patients with hypothyroidism, to whom thyroid medication was administered by experts in endocrinology.

Sycosis Barbae

Patients with sycosis barbae are divided into two classes; those in whom the eruption is of relatively short duration and limited in extent and distribution, and who have not been subjected to x-ray treatment; and those with widespread, chronic and rebellious eruptions, the majority of whom have already had x-ray treatment, with or

without sequelae.

In the first group, I believe that a certain proportion is susceptible to cure by x-ray therapy in fractional weekly dosage, up to a maximum of six unfiltered quarter-unit skin doses, combined with the mechanical depilation of the hairs with tweezers, in the affected areas. Together with this procedure, the patient twice daily applies hot wet dressings of diluted Vleminckx's solution. X-ray dosage is not given up to the threshold of depilation. If I find that four to six fractional treatments at weekly intervals do not produce the desired result, I stop x-ray therapy and caution the patient against a resumption of it in the future.

In the second group, constituting the extremely recalcitrant eruptions so familiar to all dermatologists, I have succeeded in bringing about complete cures by means of persistent mechanical depilation with tweezers and the equally persistent use of hot diluted Vleminckx's solution, of sufficient concentration to cause desquamation. I believe, also, that some of these patients are benefited by injections of mixed staphylococcic vaccines, provided that these are given over prolonged periods. As an adjuvant, ultraviolet light may be used advantageously, in patients who have not received an excess of radiotherapy.

Psoriasis

The question whether x-rays should be employed in psoriasis is a controversial one among dermatologists. In my opinion, carefully controlled x-ray treatment is quite safe, if the patient understands its limitations and the dangers involved in "shopping" among other doctors and other clinics. I therefore do not hesitate to use radiotherapy in intelligent patients, in whose cooperation I have confidence. I am particularly cautious about the restriction of x-ray dosage to the palms and soles, and therefore often resort to ultraviolet light. If improvement is not evident after four or five weekly fractional x-ray exposures, I do not continue this method of treatment.

In the management of chronic, inveterate eruptions, I rely upon chrysarobin as incorporated in Dreuw's ointment, combined with tar baths, autohaemotherapy and injections of arsenic in daily ascending doses.

Chronic Urticaria

Chronic urticaria seldom responds to a single remedy; very often we are compelled to do the best we can with a variety of more or less empirieal measures, trusting that one or another might hit the target in the center. In this obstinate ailment I have obtained most satisfactory results with pilocarpine hydrochloride, in a one per cent aqueous solution, administering three drops at the beginning of medication and increasing the dose gradually up to fifteen or twenty drops, three to four times per day. In patients who do not respond to pilocarpine, especially those in whom the articaria is associated with vagatonia, atropine has occasionally proved to be beneficial. Autohaemotherapy, colonic irrigations, intravenous injections of calcium salts, medicated baths, together with the indicated restrictions as to diet must frequently be resorted to. Sedatives and hypnotics (excepting opium and its derivatives) are used to allay the itching. The effects of endocrine therapy and ergotamine injections have thus far been indeterminate in my hands.

Disseminate Neurodermatitis

Disseminate neurodermatitis is to be sharply differentiated both from the circumscribed form (lichen chronicus circumscriptus of Vidal), and from eczematous eruptions of the contact type. Disseminate neurodermatitis is a classical example of familial and hereditary allergy and as such is almost universally associated with hay-fever, asthma or infantile eczema. While these patients are not sensitive to contact irritants, as is shown by their negative patch tests, their sensitivity as demonstrated by the immediate wheal reactions, is extremely polyvalent. Due to this polyvalence, many are found to be sensitive to ten, fifteen or even fifty common substances, so that the elimination of offending substances, or desensitization, is practically out of question. Therefore therapy must usually be confined to constitutional measures and topical remedies. Owing to the fact that in these patients the skin is relatively immune to contact irritants, much stronger topical remedies can and should be used than is the case with eczemas.

Physical and mental rest is indicated in the large majority of these patients. Sedatives and antipruritic remedies, consisting of wet dressings and medicated baths, should be employed in the early stages of treatment. After subsidence of acute symptoms, I resort to a plan of treatment in many ways similar to that outlined for psoriasis; x-ray therapy is administered with due cantiou and restriction and in many instances its

action is eminently satisfactory. But in others it is helpful only up to a certain point, so that radiotherapy must be stopped. In the latter class, I believe the best and quickest results can be obtained by the use of a week Dreuw's ointment, containing only from two to four per cent of chrysarobin and salicylic acid, combined with autogenous blood injections, medicated baths and injections of arsenic. Some patients respond well to ultraviolet light.

Recurrent Herpes Simplex

When herpes simplex habitually recurs on a selected spot, such as the muco-cutaneous border of the mouth, or on a circumscribed area on the trunk, and when the affected area is dime-sized or less, permanent cures are sometimes obtained with one or two sub-erythema doses of x-rays, administered at intervals of three or four weeks. When herpes simplex, instead of recurring in situ, develops into a widespread eruption and shifts its site of attack in successive recurrences, radiotherapy is contraindicated. In recent years, I have succeeded in curing the latter form of eruption with ordinary vaccination, using the vaccine supplied by the Department of Health; so that I now resort in all cases of recurrent herpes simplex, to this remedy. The effectiveness of this procedure does not seem to depend upon the vaccination "taking," as the majority of cases have been cured whether the vaccination "took" or not. The vaccination may be repeated several times, at intervals of approximately three weeks to a month.

Epidermophyton and Monilia

The important therapeutic problem in infections with epidermophyton and monilia fungi consists mainly in combating the secondary and concomitant eruptions—the epidermophytids and moniliids. These lesions, of which the patients complain most, are practically sterile, so that most of our topical remedics are anti-eczematous rather than antiparasitic. It is superfluous for me to recapitulate the much-discussed and much-written-about local remedies employed in attempts to eradicate the primary foci.

In cases which have proved rebellious to all other forms of treatment, I believe that trichophyton desensitization treatment (as first practiced by Sulzberger and Wise) has its distinct value. This consists of repeated intradermal injections of both epidermophyton and monilia vaccines, until the skin of the patient has become entirely desensitized to these extracts. As it is often difficult to decide in the individual case, which of these two groups of fungi plays the most important role, I believe that desensitization with the combination should be made a routine procedure. This therapy is not without its dangers and I use it only in refractory cases of long standing. As in all methods of hyposensitization, there is the risk of the creation of an increased state of hypersensitivity, with a resultant spread, increase and flare-up of the lesions. It is for this reason that I do not believe that this therapy should be recommended at the present time, as a routine procedure in general practice.

SOME PERSONAL IMPRESSIONS OF PRESENT-DAY SYPHILOTHERAPY By JOHN H. STOKES, M.D., PHILADELPHIA, PA.

Composed of the Syphilis Clinics of Johns Hopkins, the Mayo Clinic, University of Michigan, Western Reserve, and the University of Pennsylvania. Read before the Section on Dermatology and Syphilology at the annual meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

ADDRESS you today, as always apologetically, charged as I am with what is to me the almost impossible task of selecting personal impressions in a field so extended as that of the treatment of syphilis. I have decided to include the treatment of early syphilis because in it lies the foremost preventive duty of the everyday man in the field; non-specific therapy because it has an element of newness and of the future; and the situation which I believe confronts us all, but the practitioner especially, in meeting the demands of modern standards of treatment for syphilis, if we are to retain anything approaching individual as distinguished from socialized collective practice in this aspect of medicine.

The Treatment of Early Spyhilis. Twenty years of treatment experience is now culminat-

ing in the efforts of the League of Nations, and of the American Co-operative Clinical Group working with the United States Public Health Service, to evaluate results and offer principles applicable to everyday practice in early syphilis. From this material, which includes thousands of cases, from my own personal observation of the successes and failures of the practitioner, and even more from the questions he asks his syphilologic confrère, i should divide the subject into four groups of topics, with their corresponding advisory and critical principles. The questions most often asked are: "How much and what kind of treatment shall I give?" "Why can't I get or hold a negative Wassermann in this case?" "When is the patient non-infectious and fit for marriage?" "What shall I do to improve the tolerance of this patient who is reactive to any and every modern syphilotherapeutic drug?"

The advisory and critical principles that seem to me to supply the answers to these questions, as developed from the massive material referred to, plus my impressions and the literature, are these:

I. HOW MUCH AND WHAT KIND OF TREATMENT SHALL I GIVE?

- 1. Prolongation, mass and continuity (no rest periods in the first eighteen months), spell success in modern treatment. Much arsphenamin and heavy metal and continuous rather than intermittent treatment yield 2 to 7 times the results obtained by little treatment with lapses and rest periods.
- 2. No less treatment should be given to the seronegative or at least to the seropositive primary case than to the seropositive secondary eruptive case. If anything, relapse is more frequent in the first two, though cure is more difficult in the third.
- 3. An absolute minimum of five to nine injections of an arsphenamin is needed to control even 50 per cent of the tendency to mucocutaneous (infectious) relapse.
- 4. A minimum of 20, an optimum of 40 arsphenamin injections is needed to secure the best outlook for cure.
- 5. Prolonged heavy metal treatment (1 to 2 years) tends to prevent progression (cardiovascular and neurosyphilis).
- 6. Bismuth is preferable to mercury. Neither can take the place of an arsphenamin, which is still the chief modern therapeutic agent in early syphilis.
- 7. Neoarsphenamin can approach "606" in effectiveness, but only if (a) intervals between injections are shortened (3-5 days); and (b) bismuth is used in conjunction (preferably largely simultaneously).
- 8. The dosage range of 0.3 to 0.6 gm. neoarsphenamin and 0.3 to 0.4 gm. "606" should replace the Ehrlich maximum and 0.6 gm. respectively. With 0.45 gm. "914," reduce the injection interval to 3-5 days. With this dosage scale, 0.1 gm. of a 50 per cent bismuth salt can be given simultaneously in two series of 20 injections each.

No attention is to be paid to the negative Wassermann in gauging the amount of treatment, its cessation or resumption. Treat by arbitrary schedule, not blood tests,

10. Treatment, continuous for 18 months, should be prolonged to at least two years if (a) weak positive tests appear among the negatives; (b) if the blood test reverses to negative in the first three to six weeks. These cases are relapsing types.

II. WHY CAN'T I GET OR HOLD A NEGA-TIVE WASSERMANN IN THIS CASE?

1. You have allowed rest periods, or lapses have occurred in the first eighteen months. This is overwhelmingly the chief cause of the fixed positive Wassermann in early syphilis.

2. The beginning of treatment has been delayed beyond the seronegative primary

stage (diagnosed by darkfield only).

Weak positive serologic tests as warnings of relapse have been overlooked or disregarded and treatment discontinued too soon.

4. The first negative Wassermann test has been the signal for a break in treatment continuity. Better not take a test during the first six months. "Treat by schedule," not by test.

5. The cardiovascular or nervous system may be involved. Investigate by physical ex-

amination, x-ray, and spinal puncture.

6. Neoarsphenamin yields 1.5 times as many delayed reversals to negative in the blood tests of the first year as "606", but the second-year results show less disparity.

III. WHEN IS THE PATIENT NON-INFECTIOUS AND FIT FOR MARRIAGE?

1. After five years from onset in the average case, well and continuously treated at the outset (semen still questionable). There is relative freedom from infectious relapse after the second year.

2. Under absolute mechanical protection in intercourse during the above period, with kiss-

ing banned.

3. While receiving a therapeutically active arsphenamin (exception, arsenic-fast cases or therapeutically inactive neoarsphenamin) with heavy metal (bismuth).

4. Probably, but not certainly, after receiving 20 arsphenamin injections with "normal" therapeutic and serologic response.

5. No satisfactory rules applicable to (1) women; (2) relapsing types (9 to 15 per cent of patients); (3) chronic alcoholics and periodic drunkards. Physical examination of mouth, anus and genitalia, education of the patient, and persistent or relapsing positive blood tests give the only warnings.

IV. WHAT SHALL I DO TO IMPROVE THE TOLERANCE OF THIS PATIENT WHO IS REACTIVE TO ANY AND EVERY MODERN SYPHILOTHERAPEUTIC DRUG?

1. The great destroyer of treatment tolerance under present practice conditions, is rapidly injected or carelessly prepared neoarsphenamin. Don't shake, aerate, let stand, or inject at a faster rate than one-half and preferably one minute per decigram.

2. The second destroyer of tolerance is the

violent therapeutic shock (Herxheimer) from over-dosage with the first injection. Never give more than 0.3 gm. intravenously the first time.

3. The third tolerance destroyer is fear. The hurried, apprehensive, distraught "inwardly nervous" and "spasmophilic" patient is reactive. Combat with reassurance, a painless technic, calcium, rarely sedatives.

4. The tolerance of a patient is also injured by (a) intercurrent or chronic infection, including mouth and teeth and skin; (b) the allergic state, including sensitiveness to the drugs used; (c) the high carbohydrate diet and the seborrhoeic diathesis; (d) over-dosage.

5. For treatment, use the ounce of prevention. Once established, intolerance is difficult to remedy. A revised technic, a shift of drug, patch and other tests to determine the source of trouble are essential.

Evident though it must be that I have reduced the first of my topics to skeleton proportions, pressure of time compels me to deal with it in this summary fashion.

The Non-specific Factor or Resistance Mechanism in Treatment. Ten years ago, it was easy pigeon-hole treatment effects spirillicidal and resistance-building categories -arsphenamins in the former, mercury and iodid in the latter. Today bismuth has broken in between arsenic and mercury, and the various protein, infection and fever-inducing therapeutic agents have pressed for recognition beyond the infra-limits of the therapeutic spectrum of the 1920's. Undoubtedly more will be heard of this "stimulation therapy," as Schumacher calls it, so that I risk summing up a few principles for you. First, it should be emphasized that non-specific therapy in its entire range from milk injections to malaria, is out of place as a principal reliance where a rapid destruction of spirochetes for the protection of others from infection is demanded; in other words, in early syphilis. Even Kyrle's enthusiasm for malaria in secondary syphilis admitted this limitation. In the second place, the classification of nonspecific effects by Nonnenbruch, Miller, Jaffe and others indicates that at least fifteen different processes go forward at one and the same time under any one of the various forms of non-specific therapy, so that it is unwise to credit fever, the foreign protein, the active infective agent or other item in the collective phenomena with the exclusive or even the major action. The chief instrumentalities are in all probability the stimulation and hyperplasia of the reticuloendothelial system which follows all bacterial and foreign-protein invasion; the increase in proteolytic and lipoproteolytic enzymes, the latter emphasized

by Schumacher as the principal feature of non-specific defense against syphilis; antibody formation and mobilization associated with the rise of temperature; and the local inflammatory reactions aroused at disease sites by these forms of treatment. The more recent theories, of treatment mechanism especially as summarized by Tryb, give a large place to what might be called the non-specific action of the arsphenamins on the organs and tissues of the body, as defense stimulators, in contrast with the earlier conceptions of their direct spirocheticidal action. The extremely minute concentrations of arsenicals, especially arsenoxid, which seem effective therapeutically, may be conceived to be acting rather on a cellular resistance mechanism than on the organism direct or via blood or tissue protein combinations. The hampering effect of reticuloendothelial block on the action of the arsphenamins as studied by Kritschewski and others and the stimulative effect of these drugs on the Kupfer cell (Goldzieher and Peck) are all items in point. These rather esoteric details aside, it appears that nonspecific action is an important adjuvant for many patients with syphilis, and that it is not necessary to think of malaria with its discomforts and risks as the sole means of securing From the astounding endocrine shotgun recently proposed by Photinos, Michaelides, and Klissiunnis and the ultraviolet burns and autohemotherapy of Radjka and Radnai to the various induced infection and foreign bacterial protein agents there is a wide range of choice. My personal preference based on a fair experience runs to boiled milk as an easily available, safe and quite effective method of adding defense stimulation to the routine of treatment of many aspects of syphilis, including interstitial keratitis, gumosteomyelitis, but especially the serologically resistant and the arphenaminfast case. The occurrence of permanent reversals to negative in blood serologic tests previously uninfluenced by literally enormous amounts of standard treatment, have confirmed for me the favorable impressions of Greenbaum and Wright and of Burke. The method is very serviceable within limits, also, in dealing with malignant precocious tertiarism induced by inadequate arsphenamin treatment, and in total resistance to all treatment methods which is occasionally observed in early relapsing syphilis. The technic includes the use of an "A" grade milk, boiled five minutes, the dose from 2 to 10 cc. intramuscularly once or twice weekly, alone or in alternation with bismuth salicylate. The series of injections ranges from 5 to 10, the reactions are grippelike with only occasional temperature rises,

and a little or no incapacity. Rarely nitritoid reactions and urticaria compel discontinuance. The same precautions (aspiration on the syringe after introducing the needle) to prevent injection into a vein, are essential, as in all intramuscular technic. Sinus and other focal infections which may flare up under this treatment, are relative contraindications. In view of the fact that one may encounter a specific allergy to some one of the milk proteins, it would seem advisable to do an intra-cutaneous test with a minute dose before embarking on a treatment course.

The Average Practitioner and the Demands of Today's

Syphilology. While there is a certain ungraciousness in the act of a guest who washes professional linen in public, I have relied on your well-known good nature to permit me to repeat in substance, as a closing aspect of these personal impressions, the remarks which I perhaps rather brashly made at a regional social hygiene conference when challenged by the statement from an entirent source, that while almost any well-educated physician could treat syphilis, it took a real man to treat gonorrhea. This delusion, if it is generally entertained by the profession (and I believe it is) will lead us as directly as any one route, once the public grasps the situation, toward the socialization of medical practice in my field. The average physician, to judge by my experience in reading and writing answers for columnized consultations, queries minor notes, telegrams, letters and case histories, is so far unfamiliar with both the theory and the technic of treating syphilis that the patient who places himself in his care too frequently risks not only his outlook for recovery. but even his life. Perhaps my impressions come from a stratum below the level of average performance, and I am unduly pessimistic. Yet nothing more clearly seems to indicate to me our deficiencies than the physician's reaction to his own infection at its onset. proceeds to take uncalled-for risks-no routine serologic tests, no preliminary neoarsphenamin sterilization of the infective patient, much barehanded carelessness about the mouth, throat, and genitalia, untended needle pricks, a thought for every non-syphilitic possibility in diagnosis when lesions appear, with none for syphilis. Add to these, blunders that would make angels weep; satellite buboes excised for diagnosis, neoarsphenamin given for syphilitic mucous lesions misdiagnosed Vincent's infections and neither darkfield nor Wassermann test obtained beforehand. Then when the outbreak of secondaries forces the issue, and serology, reluctantly invoked, comes to the

rescue, a ghastly procession of therapeutic blunders leading to destroyed treatment tolerance, relapse, Wassermann-fastness, malignant precocious tertiarism, and paresis. Not even the intrinsic handicaps associated with the extragenital chancre in diagnosis can exonerate us of blame for the spectacle of crass ignorance and inadequacy that our reaction to syphilitie infection in ourselves presents. We can understand the overworked physician's irregularity in treatment, and delay per se in diagnosis-but the trouble is not of that order. Practising physicians only too seldom understand the first principles, to say nothing of the teclmical practice of modern syphilology. be sure, some of the principles are only just coming to light-but many have been known for years. They have simply not been taught, and the man out of school doesn't read. Early syphilis disseminating itself through relapse and recurrence, neurosyphilis fed by non-examination of the spinal fluid, wives infected by seronegative husbands, wholesale serologic fastness, the product of the three- or four-injection "neo" course with rest periods; syphilitic mothers and children from the withheld serologic test in pregnancy; late syphilis done to death in therapeutic shock and paradox, needed malaria and tryparsamide withheld for hundred-injection series of neo, bogus colloids and the like; while failing hearts and sclerotic circulations are pushed through the malarial entrance to paradise or the infernofor and from all these things, O Lord forgive and deliver us.

The professional situation in syphilis needs reform; and though this explosion is a poor way to introduce the idea, it needs too, more expert or special acumen. Few who know the disease would be prepared to argue that it has no specialty aspects; yet few indeed ever seek expert advice about it, comparatively few specialists exist, and few specialities return a smaller interest on the investment in time and experience which they involve. needs, too, lower costs for better treatment. as Keidel, Davis and Bromberg have pointed out. You are to be congratulated in that your own state leads the country, if I am not mistaken, as the first to make darkfield diagnosis by the deferred technic available to every physician, through your State Health Department. Serologie laboratories need clinic connections and contacts to bring their results and check-ups down to earth. Instruction in syphilotherapy should be brought to the doctor by a missionary force of disinterested persons who help him to apply what one of your health officers has called "sole leather epidemiology" in tracing out the focus of the infection and its peripatetic distributors, and

and the same of th

teach the actual technic of treatment on the patient in the office. The requirements for licensure in the practice of medicine should include at least examination questions on the venereal diseases, a step which Jadassohn rated as principally instrumental in raising the venereologic practice of Germany to its present high standing. But above all, the syphilologic situation of today needs a medical profession conscious of its inadequacy, ready to learn, and prepared to organize to meet needs in this field which only organization can meet. These include, reduction in individual expense; greater system and persistence in

treatment especially of early syphilis; fewer reactions through better technic; and central facilities of a high order for the evaluation of diagnostic and treatment problems in the individual and especially the late case.

The largest folder in my office files, labeled "Consultation by Correspondence," has provided me with the impressions that I have thus incontinently poured forth upon you to justify my personal fear, that only too few supposedly well-trained physicians know how to treat syphilis. Their inability to do so appeals to me as a critical problem whose solution is a pressing need of our day.

INFESTATION OF THE VAGINA BY THE TRICHOMONAS VAGINALIS Clinical Features, Diagnosis and Treatment

By JOSEPH J. BERKOWITZ, M.D., NEW YORK, N. Y.

An explanation of charts and illustrations shown in the scientific exhibit at the Annual Meeting of the Medical Society of the State of New York, in the Waldorf-Astoria Hotel, New York City, April 3-5, 1933.

YENERAL CONSIDERATIONS: Any vagina, whether or not it be the seat of a demonstrable vaginitis, may be harboring the protozoon flagellate, the Trichomonas Vaginalis. In a series of 76 consecutive cases, evenly divided between prenatal and gynecologic patients, from private and clinic practice, there was a total of 10 cases positive for the Trichomonas Vaginalis, an incidence of 13 per cent. Of these ten positive cases, four were in the prenatal group. All of these had symptoms and signs as described below. The other six were in the gynecologic group, and included a virgin, an early post-partum patient, and a patient in the menopause. Half of this group, i.e., three cases, had no symptoms or signs at all referable to the vagina, and the organism was found only in the course of the routine examination.

The mode of infection has not been definitely determined.12 Examination of the male partner has failed to demonstrate the organism either in the urine or in the preputial smegma in the majority of cases, although the organism has been reported on several occasions in the urine of both sexes and in prostatic smears.12% The common belief is that the organism is an intestinal parasite and obtains entrance into the vagina by extension from the rectum,4 particularly if cleansing after defecation is done from behind forward, which practice is apparently very common.⁵ This belief, while not established, will explain the reinfections that are so frequently noted after apparent cure. That the bladder may be the habitat of the organism either primarily or after the condition has developed, is militated against by the very small number of cases in which the organisms are found in the urine.2 I have never found them in catheterized urine specimens in cases in which the vaginal secretion was teening

with them. What is most probable is that the organism exists in a quiescent state either as to number or to virulence in numerous vaginas, and that some injury too, or alteration in, the vaginal canal, activates them. This likelihood is borne out by the case of the virgin in this series. She had never had any vaginal symptomatology until three days after an attempt at coitus which did not proceed beyond the external genitalia, at which time a discharge appeared which was repeatedly negative for the gonococcus, but was literally teeming with the *Trichomonas vaginalis*, 50-100 to the high power field (Fig. 1); and,

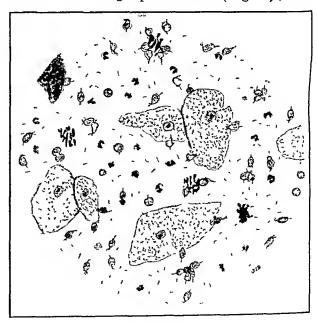

FIGURE 1

Secretion from a vagina infested with Trichomonas vaginalis as seen in a hanging-dop under the high power lens. Note the epithelial cells, leucocytes and bacteria of all kinds.

significantly, the organisms were most numerous in the vault of the vagina, and not on the mucous membrane of the labia minora or of the vestibule. Further support for this belief is found in the observation that the prenatal patients with positive smears all have active signs and symptoms, while half of the gynecologic patients harbor the organisms but do not show any of the signs or Then, too, while the symptoms of vaginitis. Trichomonas vaginalis is seldom found coexistent with the gonococcus, it will not infrequently follow upon a gonorrheal infection.2

The Trichomonas vaginalis does not invade the cervical canal.6 Examination of the cervical secretion repeatedly failed to show the organism in cases in which the vaginal secretion contained

them in great numbers.

The incidence of Trichomonas vaginalis is greater among those with low standards of per-

sonal hygiene.26

Prenatal patients suftering from trichomonas infestation have a higher incidence of puerperal morbidity than have those not so afflicted.6 But it has not been established that the organism is in itself the responsible factor, or whether its presence is an index of the degree of infectivity of the other organisms in the vaginal canal, much as the numbers of B, coli in water are an index of its pollution.

Symptoms: A patient harboring the Trichomonas vaginalis in her vagina may be free of all signs and symptoms. 16 Such symptoms as are present may vary from very slight to very profuse vaginal discharge; there may be vulvar pruritus and intertrigo; there may be chafing of the inner aspects of the thighs. These symptoms may be moderate or severe, transient or constant. It has been found that only 15% of positive cases present the typical symptoms.

Signs: There may be none. Usually there is present a greenish, yellow, foamy discharge, sometimes thin, sometimes thick. The external genitalia may be either slightly or intensely reddened and roughened. The vaginal mucosa is usually hyperemic, and presents a punctate mottling which extends into the vault of the vagina, and may also be seen on the vaginal portion of the cervix. In general, the local condition strongly resembles a gonorrheal infection for which it is frequently mistaken, and from which it must be differentiated.2

Diagnosis: The diagnosis depends on the finding of the organism in the vaginal secretion. This is best done in a hanging-drop. My technique is to insert a cotton-tipped applicator into the vagina before any examination is made or any instrument is introduced, and with it to transfer some of the secretion into one cubic centimeter of normal saline solution in a test tube. From this suspension, a drop is placed on a cover-slip, which is inverted on a plain slide or, better yet, on a hollow-ground slide, and is examined under

the high dry power. The organism, if present, will be readily recognized by its motility. It is usually pyriform in shape, and somewhat larger than a leucocyte. (Fig. 2.) While as a rule, the drop is seen teeming with them, the organisms may at times number as low as one or two per high-power field.

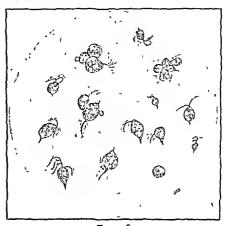

Figure 2 I arious forms of the Trichomonas voginalis organism as l arious forms of the Trichomonas voquants organism as seen under the high power lens. The drop is several hours old and is drying up, which is mimical to the flagellates. Some of them have lost their motility, and have gone to cyst(?) formation. Others have interest stowed up, so that their flagellar filaments ore seen indulating slowly. Note the voriations in size of the organisms

It is very important that a stained smear be made to examine for the gonococcus; and also that the urine be examined for sugar. Either or both of these conditions may be coexistent and should not be overlooked.

Treatment: There is, as yet, no specific treatment; nor has a permanent cure been found. De Lee says "I have never succeded in rendering the tract free from the infestation." Almost any physical or chemical agent will destroy the organism, but no agent has been found that will prevent recurrences. A satisfactory treatment is to scrub thoroughly the external genitalia, the vagina-with its rugae smoothed out by a bi-valve speculum-and the anal area, with tincture of green-soap either in full strength or diluted. This scrubbing should be continued for several minutes and should cover the entire surface of the vaginal mucosa. The canal is then irrigated with any antiseptic such as 1% lysol solution or hexylresorcinol solution or pyroligneous acid. The vagina may then be painted with mercurochrome or with 2% silver nitrate. It should then be tamponed with boroglycerin or with kaoline or

with Lassar's paste. The patient is instructed to douche every night with 1/2 % lactic acid solution or with tincture of green-soap solution. A treatment recently introduced8 consists of irrigation of the vagina under pressure with sodium perborate solution, a tablespoon to the quart, followed by the insufflation of dry guinine sulphate powder into the canal after it has been wiped dry. This treatment repeated two or three times a week for two months is said to free the tract of organisms for as long as six or eight The heat treatment with the Elliott bag given daily over a number of weeks has also been used.9 My experience has been that thorough scrubbing with tincture of green-soap, strength, together with the use of tincture of green-soap solution for douching has often given very satisfactory results as far as the relief symptoms is concerned, but recurrences have been noted. In the case of the virgin in this series where thorough scrubbing of the vaginal mucosa was impossible, complete relief from symptoms has been obtained by the instillation into the vagina every night of a syringeful of tincture of greensoap, full strength. In one case where ordinary

soap-suds were used for scrubbing and for irrigation, the organisms also disappeared. To be effective, the scrubbing should be repeated every three or four days, even during the menses and, with care, during gestation. The douche, of course, should be taken every night.

Summary: 1. The Trichomonas vaginalis may exist in the vagina in the absence of any of the usual signs and symptoms.

- 2. Infection is probably by direct extension from the rectum.
- The organism is a potential pathogen, especially in pregnancy.
- 4. Trichomonas vaginalis vaginitis resembles a gonorrheal infection, and must be differentiated therefrom.
- 5. The diagnosis is best made by the microscopic examination of the fresh vaginal secretion in normal saline solution.
- 6. Treatment is designed to bring mechanical, physical or chemical destruction to the greatest number of organisms thoroughly and persistently.

A YEAR'S ACTIVITIES OF THE BRONX COUNTY MEDICAL SOCIETY By WILLIAM KLEIN, M.D., BRONX BOROUGH, NEW YORK

A report by the President retiring at the Annual Meeting on June 21, 1933.

THE activities of the constituent counties of our State Medical Society are many and varied. Geographic location, local customs, and political administrative cooperation are factors that influence the needs and actions of the individual societies. The number of members in the society also bears a relation to its activities. It becomes evident that what is applicable to one county society may have no bearing to the needs of another; and even the same problems may require different methods of solution. There are, however, general paths along which the activities of one branch of the State Society may be helpful and lead the way to the solution of similar problems arising in another county. It would therefore seem advisable to acquaint the several counties with the problems and solutions of one unit from time to time through the common medium of the Journal. It may prove helpful and even instructive. With this point in view, I will attempt to recite a few of the problems that confronted us during my term of office, and how we tried to solve them.

The population of the Bronx County is about 1,250,000, and the County Medical Society has a membership of over 1,000. It therefore ranks as a large organization.

Examination of School Children: In New York City the examination of primary school children, if not done by the family physician, is attended to by doctors employed by the City Health Department. In the secondary schools no provision

is made for the examination of the children. The respective principals who desire to have pupils examined for the participation in a variety of athletic activities must provide or procure such examination by any method whatsoever that suits his particular fancy and condition. With a high school population in the Bronx of about 48,420 the numbers participating in athletic fields are Individual principals have emconsiderable. ployed a variety of methods to have these children examined. The majority requested the parents to have the pupils examined by the family physician. Where the parents either neglected to heed the request, or were unable to comply on account of poverty, the principal or physical director engaged the services of a private physician who examined these pupils for a minimum fee paid by the candidate for athletic endcavor. This method was unsatisfactory. In the first place, the right physician was not always procured; and the examination was at times perfunctory, while at other times it entailed the coming of the pupils en masse to a doctor's office and to wait hours before their turn came. For one physician to examine 100 pupils in an evening was considered by the County Society as unsatisfactory. Many physicians complained that their patients were enticed to the offices of another doctor. Other inimical features were entailed in this procedure.

The Bronx County Medical Society studied this problem and succeeded in making the follow-

ing arrangements:

A gentlemen's agreement was entered into between the principals of the high schools and the Bronx County Medical Society. By this arrangement all children to be examined are given slips to be taken home, and are instructed to have the family physician examine them and fill out the slips. Failing to bring in the filled-out slip within two or three weeks or reporting the inability to engage the services of a private physician, the children are examined by the County Society in the following manner: The high school notifies the County Society that a certain number of children are to be examined on a particular day. The County assigns two or more physicians, depending upon the number of pupils to be examined. The assignment is made from a list in our office. This list is headed by those members who are on our relief list. They get first call. The rest are called alphabetically from a voluntary list. Usually young men who have time and ability but not much to occupy them in their practice, are listed. The pupils pay a fee of twentyfive cents, or none, when unable. Under the able guidance and instruction of Dr. L. A. Friedman, whose experience was invaluable, these physicians are examining on an average of ten children per hour per physician. It is surprising how thorough and satisfactory these examinations are done in what seems an incredibly short time. The examining doctors receive \$2.35 per

hour. The County Society does not derive any monetary benefit from this work. It is considered a public duty and serves many useful purposes. These examinations are conducted in the schools where clerical assistance and proper space are provided by the school. The doctors are impersonal and no one can or will make any remarks to the pupil, but each dictates his findings to the secretary. Pupils found in need of care and treatment are weeded out and referred to the family physician. If unable to procure such services in private, the County Society sends them to the various specialists who treat them gratis. Under this arrangement we have examined some 9,000 children from October, 1932, to June, 1933.

The advantages of this procedure are many. In the first place the examinations are impersonal, pupil and doctor remain practically unknown to each other. Secondly, the family physician has no cause for complaint. No one is trying to entice his patients away from him. Thirdly, the County Society is responsible for the work done and no other but a member of our organization is in atendance. The principal is relieved from a great responsibility and from many complaints. Much credit must be given to Miss Gladys Adams of The Bronx Tuberculosis and Health Society whose tireless work and assistance helped in these arrangements.

Baby Health Work: Due to the impaired budget of New York City, the Health Department was forced to relinquish a number of baby health sta-This work was immediately taken over by the Bronx County Society in conjunction with various voluntary health agencies. The method in brief is as follows: When a mother cannot afford the services of a private doctor for the routine and regular examination of her baby, she reports her case to a welfare agency. The agency determines the veracity of her statement, and then gives her a card with the names of a number of physicians in her neighborhood who will care for the baby in the office gratis. This obviates the perniclous habit of going to dispensaries, and facilitates the trial period of the young medicus in helping him to become acquainted in his own neighborhood. It is perhaps of interest to know that the welfare agencies wished that the doctor receive the regular dispensary fee which these people were in the habit of paying; but we objected on the ground that it would cheapen the doctor and would undermine the average neighborhood fees. A woman will boast if she pays little, but would not advertise the fact that she is a charity patient. This arrangement was used as an argument against the reopening of these or other clinics.

Cheap Insurance Schemes: In a large community we find that from time to time certain men holding medical diplomas would evolve schemes which sound good to the unwary, but are the kind of practice that undermines the profession. Most of these are modifications of the old ten cents a week game. The public is enticed by various promises and in the long run they pay more for less. One such scheme started last year in our county. This had the added feature of making the doctor joining it pay in \$150.00 for the privilege of becoming connected with this nefarious business. Certain druggists, too, were enticed and handed over the stipulated amount. Before they were too far advanced the County Medical Society exposed them, wrote warning editorials and opened the eyes of the druggists. It promptly ended the business.

Abuse of Hospitals: In larger centers of the state municipal hospitals are often abused by those who should be in the offices of the doctors. The professional charity worker and certain political appointees seem to be infected with the purely American disease, the craving for large numbers. It is perhaps to their advantage to be able to flaunt into the eyes of the public the great good they are doing. With an array of big numbers it is easier to get larger budgets and make the positions safer. The doctors who never retracted their willingness to treat the poor gratis always felt that too many non-deserving patients are taking advantage of the hospitals, often with the guiding hand of the professional social worker. County Medical Society undertook to investigate one large, typical, municipal hospital. After obtaining permission from the city authorities to do so, a committee was appointed for this purpose. The expense was borne partly by the County Society treasury, already impoverished, and partly by voluntary contributions by one set of our members. The committee engaged the services of a disinterested organization, and the investigation was as thorough and as unbiased as was expected. We believe that it is the first time that a County Society investigated independently a municipal hospital. The report will be of interest not only to us but to all organized medicine. The final report is expected some time in the Fall.

Private Hospitals: We have in our county about twenty-four private hospitals and sanatoria. In their eagerness to attract the doctors and their patients, some of these have established a sort of bonus for the doctor who refers cases to them. This practice is widely spread in large cities. Our county considered this both unethical and possibly leading to practices that are not in keeping with The Comitia Minora called the our tradition. proprietors of all private hospitals to a conference. After pointing out to them that this is a pernicious practice and what it may lead to. an agreement was entered into between the County Medical Society and the private institutions. This agreement is to the effect that they pledged themselves to refrain from any unethical and hidden practices. The county issues a certificate of approval to each subscriber and will see that only those which are in the agreement will be patronized. The great majority have gladly signed the agreement.

Patent Medicine Advertisements: Some local papers carried advertisements of the usual type of patent medicine. This particular one was a harmful drug acclaimed as non-injurious. The County Society with the cooperation of the Health Department prevailed upon the particular paper and the practice was discontinued.

Public Instruction: Our regular radio talks are in full progress. During the year our members broadcast about fifty talks. These were written and censored by our own men. Another fifty talks were given to mother's clubs, teachers, and lay organizations. We felt that the teaching of the public should be in the hands of organized medicine and not relinquish it to lay people who are interested in one thing or another but not in the doctor. The rôle of the family physician is always stressed as the bulwark of the family's well-being.

A number of other activities that originated in our County Society were carried with cooperation and unstinted help of the five other county societies comprising greater New York organized medicine. The coordinating committee of the five counties facilitates matters greatly for each individual county.

I wish to take this opportunity to express publicly my sincerest thanks to that indefatigable and tireless worker for organized medicine, Dr. C. E. Podvin.

TREATMENT OF CARCINOMA OF THE FUNDUS

By THOMAS P. FARMER, M.D., SYRACUSE, N. Y.

Read at the Annual Meeting of the Medical Socity of the State of New York, at New York City, on April 5, 1933.

DESPITE the disparity in figures in published reports of series of cases of carcinoma of the cervix and the corpus uteri, it can be fairly safely stated that cancer occurs three or four times more often in the

cervix than it does in the body of the uterus, and that the percentage of cures in the latter condition are probably twice as high as those of the former. Because carcinoma of the fundus is apparently more frequent than formerly was supposed, and because of the relatively good chances of cure, this condition merits more attention that has been paid to it in former years. It is especially important from a public health standpoint, not only on account of the possibility of increasing the percentages of cures, but also because it affords splendid evidence of the frequent cure of a malignant growth by a major surgical procedure.

Outside of the fact that bleeding is a leading symptom of both conditions, cancer of the cervix and of the corpus have little in common. Due to the obvious anatomical histological and physiological differences existing between the body and the neck of the uterus, neither the marked contrast between disease processes in these two locations nor the resulting differences in the manifestations of disease is sur-The differences between cancer of the cervix and cancer of the body are especially notable and have been frequently emphasized by many previous writers. That a better appreciation of these differences would materially aid in the early recognition and the proper treatment of these two diseases would seem most probable.

Although the etiology of cancer of the fundus is not clear, some quite definite facts seem to point to certain conditions as having a bearing on this problem and being of some practical importance. The average age of cases of cancer of the body of the uterus is probably between 53 and 54 years. It is more significant, however, that nearly 50 per cent of these cases occur in the sixth decade of life and approximately 75 per cent of the cases occur during the sixth and seventh decades. Apparently a much larger proportion of cases of cancer of the body occur in a smaller age group than is the case with cancer of the cervix, and this age group is distinctly a postmenopausal one. Donald and Shaw reporting on 177 cases state that only one and threetenths per cent of these cases were pre-menopausal and that in the cases in which bleeding had not stopped, the continuation of menstruation for a longer time that would seem to be normal was frequently due to the presence of other pathology, such as fibroids. Although cases of cancer of the corpus have been reported in women as young as nineteen years of age and while most all observers have seen patients under forty years of age, it can be fairly safely stated that the disease is principally associated with the period of atrophy following the menopause and that this probably bears a relation to the origin of cancer of the corpus. The age incidence of this disease without doubt is of great importance in emphasizing the responsibility of definitely determining the cause of all post-menopausal bleeding.

Fibroids accompany cancer of the body of the uterus in about 25 per cent of cases. Whether this is greater than the normal incidence of fibroids cannot be definitely stated due to our lack of knowledge of just what the normal incidence of fibroids happens to be. Nevertheless, it is the opinion of most authorities that this figure does represent an increase. Ewing has reported the observation in three cases of carcinoma developing in the mucosa overlying small fibroids. Probably of greater significance are those reports in which cancer of the fundus, although a rarer disease, has been found associated with fibroids more often than cancer of the cervix. These observations while only suggestive point to the necessity of the treatment of fibroids of any consequence at or after menopause and emphasize the danger of fibroids by their presence masking the symptoms of cancer. Because of this fact, the visual examination of the endometrium for coexistent carcinoma of the corpus should be a routine part of every supravaginal hysterec-

Several cases of early cancer developing in a hyperplastic endometrium have been reported. Because this occurrence is relatively infrequent, while hyperplasia of the endometrium is a fairly common condition, it has been questioned whether this is more than a coincidence. Fluhmann and Stephenson while apparently inclined to this view, state that "the possibility of coincidence, no matter how slight, does exist and one must always bear in mind the importance of careful study of all tissue obtained from the uteri of women with abnormal bleeding at the time of the menopause." Taylor who has made an extensive study of hyperplasia of the endometrium gives the following wise advice: "In patients of the menopause age and older an adequate dose of radium is particularly indicated, certainly as the most efficient method of controlling bleeding, possibly as a prophylactic measure against the development of cancer." Because I do not know of a case of cancer of the fundus, having occurred in a large number of women treated by curettage and radium for hemorrhage due to endometrial hyperplasia, most of whom must have passed through the age period of the greatest incidence of this disease, I am quite in agreement with this statement. The observations in carcinoma of the rectum made by Lockhart-Mummery and Dukes, showing epithelial changes beginning with hyperplasia and continuing through adenoma to cancer would suggest the strong possibility of such relationships in the uterus,

The contrast in the clinical course and the extension of cancer of the body and cancer of the cervix is especially marked and undoubtedly of much practical importance. Although cancer of the body may show very early recurrences and have a rapid course, it is usually a disease of longer duration than cancer of the The average duration of symptoms before operation has been reported as varying from one to nearly two years. The fact that death from recurrences occurs eight years postoperatively would question the validity of statistics based on a period of five-year curability. The disease offers no characteristic physical signs, pelvic examination frequently being negative. It is apparent, therefore, that diagnostic curettage is absolutely essential in many cases for the prompt recognition of the disease, though the Clark test may be helpful if positive. Because the disease does not tend to invade the parametrium but does show a large number of visceral metastases, notably in the ovary, it would seem possible that the disease is frequently spread by transplantation and that this often occurs through the tubes, as explained by Sampson. quency with which the vagina is secondarily infected would also suggest secondary invasion by transplantation. Nevertheless, the disease may also be disseminated by the lymphatics and blood vessels. However, the transplantation theory cannot be disregarded, despite objections to it, and consequently, great care should be paid to the possible spread of the disease through this method during pelvic examinations, curettage, the application of radium and at hysterectomy.

Although radium has largely supplanted surgery in the treatment of carcinoma of the cervix, the opinion of the majority of surgeons would seem to favor operation as the choice of treatment for cancer of the uterus, not only in the early cases but also those cases somewhat moderately advanced. cancer of the uterus which have been cured after simple curettage and after supravaginal hysterectomy have been reported. of these methods can be relied upon as a safe form of treatment. The entire uterus should be removed in as much as some of the lymphatics in the body of the uterus extend to the cervix and metastasis may occur through this route. As secondary growths in the ovary have been noted in as high as ten per cent of the cases, bilateral salpingo-oophorectomy should be done. The lymphatics draining the fundus of the uterus flow directly into the lumbar glands and not into the pelvic Consequently the wide removal of the broad ligament and perimetrium, necessary in dealing with carcinoma of the cervix, is not essential with carcinoma of the body. Bearing in mind the possibility of transplantation of adeno-carcinoma of the corpus, the pre-operavaginal preparations should include closure of the cervix by suture and packing of the vagina. After the abdomen has been opened attention should be given to the closure of the tubes and avoidance of puncturing or compressing the body of the uterus during the operation for the same reason. Personally, I feel it highly desirable to remove the tubes and ovaries at the beginning of the operation before the uterus has been handled at all. While there is a possible danger of transplanting the growth during curettage, a comparison of a group of cases curetted at least a few days before operation with a group of cases not submitted to curettage, shows no actual difference in results. In view of the fact that curettage is imperative in about thirty per cent of the cases in which the diagnosis is doubtful and that the diagnosis will be made in another twenty per cent of unsuspected cases, the procedure should not be omitted because of any theoretical considerations, though it should be used carefully and judiciously. The radiation treatment of fibroids or glandular hyperplasia without preliminary curettage excluding the exceptional case should be strongly condemned.

Radium is of considerable value in the treatment of cancer in the body of the uterus. The statement frequently made that adenocarcinoma of the corpus is not influenced well by radium cannot be substantiated in view of the reports showing cures running from twenty to fifty per cent of all cases. It should be particularly remembered that many of these cases were treated with radium because they were either unsuitable or too far advanced for The objections to the use of operation. radium are the difficulty of estimating the proper dosage, of making the correct application and of observing the progress of the reaction to its use. It is quite possible that if radium could be properly applied it might cure as many and possibly more cases of cancer of the body than is now accomplished by surgery. In the highly malignant types it would seem to give a greater chance of cure than operation. Certainly all cases in which surgery is refused or contraindicated, as well as postoperative cases showing recurrences should have the possible benefits of radium. The question as to the advisability of using radium preoperatively is an unsettled one. Objection has been raised against its use on the grounds that the radium tube in the uterus might act like a piston in a cylinder in forcing carcinomatous tissue from the fundus through the tubes. With proper care in the introduction of the radium tube after careful dilation of the cervix, avoiding tight packing of the vagina and holding the tube accurately in place by a mattress stitch through the ecryix so as to prevent its subsequent dropping into the vagina, such an occurrence should be obviated It is, therefore, my plan to use radium in all suspicious cases where it is necessary to wait for a histological diagnosis. No great technical difficulty has been experienced at the time of hysterectomy because of the previous Hysterectomy has usually radium treatment been postponed until four to six weeks after curettage unless it has been possible to operate within a few days External radiation should promptly he resorted to in the cases treated by radium and in which hysterectomy as omitted

Because carcinoma of the corpus is frequently cured following an operation after symptoms have been present for a comparatively long period, many physicians feel that the malignancy of this growth is rather low. While the various grades of maliguancy are

seen in the corpus, in a general way these growths may be just as malignant as those involving other parts of the body and their more favorable course is due to the anatomy of the parts involved, especially the protection to the extension of the growth by the muscle of the uterus. When the scrosa has been penetrated, it has generally been my experience that the course of the disease has been rapid and most unsatisfactory and I would agree with Ewing and Norris that the chief point in the favorable prognosis of uterine cancer is the integrity of the myo-Norris analyzing his cases from the metrium standpoint of duration of symptoms finds that there were 565% three year cures when symptoms had not been present longer than six months, 31 2% such cures when symptoms had been present from seven to twelve months, and 178% cures when symptoms had been present over one Undoubtedly the most important single controllable factor of benefit to the patient in the management of cancer of the fundus, is, as with growths in other locations, the early diagnosis of the disease

LABORATORY AIDS IN THE DIAGNOSIS OF UNDULANT FEVER

Issued by The New York State Association of Public Health Laboratories, October, 1933

That the diagnosis of undulant fever can rarely be made with certainty by clinical observation alone is now quite evident. The course of the disease is highly variable, the chief complaint may be any one of a large variety of symptoms, and the total symptomatology may constitute a clinical picture which resembles diseases as different from one another as influenza, typhoid and rheumatic fevers, tuberculosis, pyelitis, acute cholecystitis, and appendicitis. Some patients may not be acutely ill. Headache, insomnia, and a feeling of depression may be the only complaint. Clinical records, together with the results of agglutination reactions done on blood serum sent to the laboratory without any suspicion that the patient had undulant fever, have made it clear that the laboratory findings may often be of primary importance in the diagnosis of undulant fever.

LABORATORY AIDS IN DIAGNOSIS

I. The Agglutination Reaction. Main reliance must be placed on this test. A marked agglutination reaction with a suspension of B. abortus culture in a 1:80 or higher dilution of the patient's serum is almost conclusive evidence of past or existing infection induced by a microorganism of the abortus-melitensis group. The agglutination reaction may, however, be negative during the first two weeks of undulant fever and sometimes even longer. Repetition of the test with later specimens of serum is, therefore, frequently necessary. Occasionally, when patients are very ill, the agglutinative properties of their serum may be

slight. While serum from cases of tularemia or undulant fever may agglutinate suspensions of both B. tularense and B. abortus, the former infection is so rare in New York State that this seldom needs to be considered.

II. Blood Cultures. The isolation of B. abortus from the blood stream may be accomplished in a limited percentage of cases only by the very prompt inoculation of suitable culture medium and its incubation under special conditions. On first isolation the growth of the organisms is slow, so that two weeks or longer may be required before sufficient growth for identification has occurred. Failure to isolate the microorganism has little significance.

III. Stool and Urine Cultures. B. abortus can seldom be isolated from feces or urine. Attempts to demonstrate the presence of the microorganism in these discharges are usually futile.

IV. Skin Reaction. Intradermal tests with killed suspensions of B. abortus for evidence of undulant fever must still be considered in the experimental stage. Reports indicate that severe reactions occasionally occur.

EPIDEMIOLOGY

In New York State, cattle or dairy products have been shown to be the usual source of the incitant of undulant fever. Hogs or goats have seldom been implicated. Contact with cattle having infectious abortion disease or the use of raw milk or cream from such animals has generally been found to have occurred when cases of undulant fever are studied.

EXHIBIT ON METABOLISM

The scientific exhibits on metabolism in the New York Academy of Medicine during the Graduate Fortnight ranked among the largest and most complete that have ever been assembled on any one subject. While the exhibits were prepared by specialists and research workers, yet they were in a form that a general practitioner

could comprehend In fact the exhibits were designed to educate the general practitioner in new fields of knowledge which his successors will enter and occupy. There are no bounds to the field of medical research, nor to the opportunities for a physician to extend the scope of his knowledge and usefulness

TRUTHFUL ADVERTISING

Commercial advertising is paid propaganda setting forth only the virtues and attractions of a ware that is for sale. It is subject to all the exaggerations in which enthusiastic salesmen indulge; and when uncontrolled, it may be downright deception. "Buyer, beware" is an ancient saying that still has its force.

When a storekeeper deliberately makes a false statement to a buyer, through which the customer suffers harm, he is subject to the penalties of the law. But when a newspaper or magazine publishes misleading statements in an advertisement, the seat of responsibility is often problematical.

The most direct law dealing with fraudulent advertising is the Federal Food and Drugs Act, which includes cosmetics in its scope. But this law is ineffective for it deals only with labels on the packages of goods. A dealer can make grossly exaggerated claims and statements in newspaper advertisements, when the law forbids him to place the same claims on a package of his goods. The dealer has accomplished his purpose when he has sold his goods, and yet it is only then that the buyer reads the label on the box or bottle. A label is usually a colorless statement of vague claims, while the advertisement is a lurid promise of miraculous results.

A new Food and Drug Bill that is under consideration by Congress, extends the provisions of the present law to newspapers and radio broadcasts. However, it makes a distinction between the published article or broadcast, and the advertiser. It would exempt the publisher or broadcaster from liability for false statements; but would hold the manufacturer or dealer responsible for the statements in the advertisement. This is a wise provision, for a publisher cannot be expected to have facilities for judging the truth or deception of an advertised statement; but a dealer or manufacturer is supposed to know the nature and value of the product which he handles.

The principal responsibility which the proposed law would place upon the publishers is that of supplying the names and addresses of the advertisers of suspicious articles.

The N.R.A. code of fair practices will assist in the promotion of truthful advertising, and also in the enforcement of the proposed law, for under it a dealer can report an exaggerating competitor to the Federal Government.

The proposed extension of the new Food and Drugs Act is an important step in raising the standards of advertising.

INSURANCE OF HOSPITALIZATION

The Hospital Council of Cleveland, Ohio, has submitted to the State Insurance Commission a plan for the insurance of hospitalization of individuals on a group payment plan, which is described in the November issue of the Ohio State Medical Journal. Specifically, the article discusses the Ohio insurance law as applied to the plan, and is based on the opinion of the Attorney General given at the request of the State Superintendent of Insurance. The general principle of the opinion is that corporations which engage in health or sickness insurance must allow the insured their free choice of physicians or hospitals; but that a hospital may make direct contracts with citizens of the county in which the institution is located.

The Cleveland plan is a proposal to form a corporation called the Hospital Council which should be the agent of fifteen hospitals in selling insurance of hospital service to specified groups of individuals. Since the corporation is not for profit, but merely acts as the agent of the fifteen hospitals, the Ohio law would be observed.

The plan offers ward service to an individual at \$7.20 per year, and semi-private room service at \$9.00 per year; and goes into detail as to what nursing, laboratory, x-ray, and other

services are included and what kinds of cases are excluded. It also limits the service to twenty-one days in any year.

The proposal also limits the insurance to persons who are in the employed class; but further stipulates that they must be in groups of not less than ten working for any one employer. The service is to be given to the employed persons only, and not to their families. It will therefore be seen that the Cleveland plan would cover only a corner of the field of medical insurance, and yet would require a force of salesmen, managers and clerks to keep track of the business.

There is nothing inherently wrong in the general principle of insurance for hospitalization; but there are numberless objections to any specific plan that has been proposed. However, the prospect of attaining success is alluring, and will doubtless spur promoters to attempt to form hospitalization insurance groups, until some one succeeds in pointing out a practical plan. At present the assumption of the risks of the organization of insurance groups belongs to business men rather than physicians. But any insurance man acts unwisely if he fails to seek the advice of a county medical society.

MEDICAL PROGRESS

The Treatment of Glaucoma.-B. W. Rycroft says that masmuch as the cause of glaucoma is unknown the treatment, though adequate, is empirical. The treatment of acute glaucoma consists in the following procedures: (1) The patient is put to bed sitting up; (2) aspirin or morphine is administered for the pain; (3) leeches are applied to the outer canthus; (4) miotics are instilled locally; (5) hydragogue cathartics are administered; (6) an electric eyewarmer is applied; (7) tension is reduced by diathermy or saline, followed (8) by operation under subtendon or retrobulbar novocaine anesthesia. The treatment of chronic glancoma must always commence with: (1) a medical investigation of the cardiovascular system with due attention to hyperpiesis and renal dysfunction; (2) the elimination of gross foci of sepsis; (3) the guarded use of mioties until such time as deterioration of vision is no longer controlled; and (4) coincidentally the use of prolonged local eye massage. The indications for operation in chronic glaucoma consist in an increased frequency of acute exacerbations, in an increase of relative scotoma and field loss, and in a persistent high tonometric tension. The ideals to be attained by operation are that filtration must be spread over a wide area, that it must be permanent and adequate but not excessive, and that there must be a minimum of trauma, no risk of late infection and a good cosmetic result. The Elliot operation approaches these ideals most closely.

In secking a physiological basis for the treatment of glaucoma, the author has studied the effect of histamine on the eye and endeavored to find whether this substance was present in the aqueous in cases of acute glaucoma. By animal experiments it was found that histamine injected into the anterior chamber of the eye the intraocular pressure all the while being kept constant-produced a rise of intraocular pressure, which was not brought about by an equal amount of saline. When histamine was injected into the blood stream there occurred a fall of blood pressure, and a coincident rise of intraocular pressure, provided the capillaries maintained their tone. Friedenwald has found that the histological findings of animal eyes into which histamine has been injected conformed in close degree to the pathological findings of eyes removed for acute glaucoma. There appears, then, to be a close relation between the effects of histamine on the eye and the picture of acute glaucoma. In four cases of primary acute glaucoma equal amounts of

aqueous and saline were injected on the flexor surface of the forearm. The next day histamine was injected. In no case was a flare produced by the injection of aqueous, although all the patients reacted to histamine. These experiments have, therefore shown no vasotoxic substance in the aqueous.—British Medical Journal, September 16, 1933, ii, 3793.

The Pathogenetic Significance of the Enterococci.-It is a mistake, says M. Gundel, in the Deutsche medizinische Wochenschrift of Sept. 8, 1933, to suppose, as has been done until quite recently, that pathogenic action on the part of the enterococci, as regular inhabitants of the lower part of the intestine, is an exceptional phenomenon. Both microbiologists and elinicians have, within the last few years, been justified in taking an increased interest in these microorganisms, which have not in the past been accorded their proper place as agents of disease. Two types, A and B, of enterococcus, are now recognized. Type A upon blood agar is characterized by slender, blackish, small to medium size colonies with a whitish center and a greening of the nutrient medium in greater or less degree. Type B, on the other hand, exhibits a considerably more luxuriant growth, the whitish colonies resembling staphylococcus colonies, which are for the most part marked by a delicate black border, and which grow luxuriantly on agar. The latter is the type that predominates in the lower intestine. Foremost among infections of the gastrointestinal canal caused by the microorganisms are inflammatory changes of the bile ducts, which push into the background those of the upper intestinal tract, while a special role in the pathogenesis of appendicitis has recently been attributed to the enterococci. These organisms not infrequently serve also as the exciting cause of appendicitic abscesses and postappendicular peritonitis. In addition, though yielding first place to the colibacilli, the enterococci are observed as the next most frequent cause of cystitis and pyelitis. Although the pathogenic role of the enterococci is still a debated question in many of these diseases, no such doubt is any longer possible when these microorganisms are seen in pure culture as exciters of septicemia. Here the incontrovertible diagnosis of enterococcus may lead to recognition of the focus, whether in the biliary tract, the intestinal canal or the urinary tract. But also from a clinical-diagnostic and prognostic point of

view, a definite diagnosis is especially important with reference to enterococcus endocarditis, which is strictly to be differentiated from endocarditis lenta. The enterococcus problem has, therefore, an importance beyond that of pure biologic research. The differentiation and identification of the members of the streptococcus group do not simply constitute a game for specialists, but are also of great importance for the general medical practitioner.

Attempts at Therapeutic Malarialization in Acute and Chronic Leucemia.—Benedetto De Luca states that he recently had an opportunity to observe the effect of the therapeutic use of malaria in 2 cases of leucemia, the one acute, the other chronic. In the former he injected into the blood the parasite of quartan, in the latter that of tertian, malaria. In both cases the temporary effect was very striking, the number of white cells diminishing in marked degree, while at the same time the differential count improved. Thus in the acute case, a white cell count of 251,000 per cubic millimeter had fallen, after 7 chills, to 48,000, and immature cells were reduced from 80 per cent to 16 per cent; in the chronic case a fall from 220,000 to 115,000 white cells was observed, and of immature cells from 51 per cent to 15 per cent. There was also a very marked reduction in the size of the spleen in both cases, but especially in the chronic one, in which the enormous size of the organ had occasioned almost intolerable discomfort. When the malarial attacks came to an end, however, there was a strong tendency for the leucocytes to multiply to their former number and for the differential count to assume again its former large percentage of immature forms. The spleen also exhibited a tendency to return to its former excessive size, though not so rapidly as might have been expected from the simultaneous multiplication of leucocytes. The liver behaved similarly, but in less degree. Subjectively both patients felt much better in the period immediately following the cessation of the chills; but during the period itself in which the explosive attacks were appearing, both were greatly prostrated; in the acute case, particularly, the patient begged that the treatment be stopped, insisting that he could not possibly bear the fever any longer. This is explained by the fact that while the leucemic picture was improving, the red blood picture was undergoing a marked impoverishment. In other words, the effects were at the same time beneficial and injurious. This makes it desirable to limit the number of febrile attacks to 10 or 12. After the attacks, the former hematopoiesis was resumed rather rapidly. In fact the maximum clinical improvement coincided with the period of hematic repair, notwithstanding the contemporaneous increase of white cells. This improvement in hematopoiesis, though temporary, may persist for a month or more. In the acute case, despite the use of deep roentgenotherapy of the spleen, carried out twice with an interval of 50 days between sittings, the improvement was rather ephemeral and less marked than in the chronic case, in which the diminished tendency of the disease to progress must be taken into account.—Rifirma medica, August 12, 1933.

The Treatment of Cancer with Connective Tissue Extracts.—H. Searle Baker is of the opinion that the excessive growth of cells is controlled by substances secreted by the connective tissue of their area. If a cell or group of cells be deprived of adequate inhibition, by lymph stasis or actual failure of secretion, it will reassert its fundamental tendency toward unlimited growth. It is not impossible that the inhibitory factor is an enzyme, and for various reasons it is considered that its major function is lipolytic. It is secreted in the connective tissue and functions to the best advantage in the area of its secretion. Working on this hypothesis, treatment is designed to introduce this essential substance into the carcinoma by the intravenous administration of an extract of connective tissue derived from an area, in the pig or cow, corresponding to that of the primary growth in the patient. The result of this treatment has been that the patient loses his cachectic appearance and the carcinoma diminishes in size and becomes attenuated in vigor. Thirteen cases are reported to illustrate the definite value of this procedure in carcinoma. The method employed in making a breast extract consisted in taking 33 Gm. of connective tissue from a sow's breast (for breast carcinoma) immediately on the death of the animal. This was thoroughly ground in 10 c.c. of glycerin with fine sand. To this 90 c.c. of water was added and the whole filtered at the maximum pressure consistent with effective sterilization, through a Seitz filter; 0.5 per cent phenol was added and the reaction adjusted. To this 0.5 per cent sodium phosphate was added and the pH checked. Then 0.1 per cent sodium taurocholate and 0.1 per cent sodium glycocholate were added, the pH adjusted, and the extract was boiled in nitrogen. The activity of this extract is only retained for from 10 to 14 days, when precipitation may occur. The preliminary dose was in every case 1 c.c. and subsequent doses were gradually increased, the maximum dose employed being 25 c.c. method of choice is the intravenous route, and the interval between doses should not exceed four days. The injections are accompanied by slight temporary discomfort. The author considers the results obtained by this treatment to be definitely promising and hopes that other workers will be stimulated to follow up this line of inquiry—The Lancet, September 16, 1933, cenny, 5742

Acute Poisoning from Potassium Permanganate. - According to Vincenzo Mario Palmieri, despite the widespread use of permanganate of potassium in industries and in medicine, cases of poisoning by this substruce are quite rare, its irritant and caustie properties render its use repugnant to would-be suicides and too easily detected for purposes of homicide, while its characteristic color and immediate causticity make its accidental ingestion rather improbable unless the victim's Palmieri resensorium is already clouded ports the strange case of a man who was brought to the hospital in extremis by two of his friends, who stated that he had been taken suddenly ill while drinking in a tavern first impression, accordingly was that he was suffering with acute alcoholic intoxication, he was in a state of unconsciousness, with extreme pallor, lips and oral mucosa swollen, a blackish fluid drooling from his mouth, while he made meffectual attempts to vomit pulse was thready, its rate 125 per minute, and his respiration of Cheyne Stokes type. On the following morning, when his temperature rose to 398°C, with abdominal distention, hippocratic facies and complete coma it became evident that this was no common alcoholic poisoning, and a consultation resulted in a diagnosis of acute appendicitis and peritonitis Operation was out of the question under such grave conditions, and the patient died 31 hours after admission without regaining conscious-An anonymous note now reached the hospital stating that the death was due to a "powder" put into his wine by friends vestigation resulted in the discovery that the poisoning was the result of a practical joke played by his drinking companions upon a man already in an advanced state of alcoholic ntoxication The friends of the victim knowing that he was using local irrigations of potassium permanganate for a gonococcus infection had conceived the idea of giving him reatment per os to help along his cure. They had accordingly introduced 10 gm of the substance into his red wine during his temporary absence from the table. On his return he had drunk the glassful at one gulp then almost instantly was seized with contortions became deathly pale, groaned with agony, tried ineffectually to vomit and fell forward unconscious upon the table Autopsy revealed a perforation of the posterior wall of the stomach and the presence of acute peritonitis, with signs of caustic action throughout the entire

alimentary canal There was recovered from the stomach 0.173 gm potassium permanganate (calculated from the manganese oxide found there)—Riforma medica, August 5, 1033

Carcinoma of the Male Breast - Judson B Gilbert writing in Surgery, Gynecology and Obstetrics, October, 1933, Ivii, 4, presents a clinical and pathological study of 47 cases of male breast cancer, six of which were pre-viously reported by Wainwright (1927) Male breast cancer comprised 124 per cent of ad missions to the breast chuic of the Menional Hospital and only 014 per cent of all caneers m males Of the 47 patients, the eldest was 83 years of age, while the youngest was 31, the average age was 514 years. The left breast showed a slightly higher percentage of involvement than the right. It appeared that in this series heredity was of secondary importance as a causative factor of male breast cancer Although "occupational mastitis," due to chronic irritation, is not infrequently a pre cancerous lesion, a previously existing benign tumor was noted in only three patients, or 63 per cent of the series. The incidence of trauma was recorded as a possible etiological factor in 14, or 29 per cent of the cases, but no proved instance of a single trauma causing cancer was noted in the series Emphasis is laid on the coincidence of gynecomastia with caucer, and evidence of their relationship is considered on experimental, clinical and anatomical grounds In this series nine patients, or 19 per cent of the entire series, presented hypertrophied mammary glands, corresponding in general topography to the female breast. It would seem that breasts of this type are more likely to be the seat of cancer The symptomatology. pathology, and distribution of metastases in the male breast correspond to the well recognized manifestations of mammary cancer in general The prognosis of cancer of the male breast is poor Five patients observed prior to January, 1928, survived five years or 11 per eent, of these 26 patients, are still alive without evidence of disease recommends irradiation therapy as a valuable adjunct in the operable cases and as a palliative measure in the inoperable cases Better knowledge, more varied and better modalities and the fact that the skin will stand heavier dosage than was previously supposed, offer the radiologist a greater opportunity to cope with this disease As a means of relieving the constant pain of bone metastasis and as a method of treating local recurrences radiation should be recommended in these hopeless cases

The Modern Treatment of Diseases of the Heart—Curtis Bain, writing in the Practitioner,

October, 1933, cxxxi, 4, expresses views regarding the sequence of events in cardiac failure based upon work as yet unpublished. He says the fundamental result of structural disease of the heart is that the circulation is slowed. Some forms of heart disease, such as mild degrees of mitral stenosis and regurgitation, are not incompatible with normal circulation speed. Others may have a little slowing and yet be able to live normal lives, as in many cases of aortic regurgitation and liyperpiesis, and in some with myocardial lesions. When the blood travels at about two-thirds of the normal speed, there will be symptoms of cardiac failure on exertion, dyspnea, and angina pectoris. For minor attacks of nocturnal dyspnea rest and opiates are indicated. Adrenaline may give relief, but cannot be depended upon. prognosis in cases in which the attacks recur is not good. When attacks of angina pectoris increase in frequency, it is not necessary to confine the patient to bed, but he should not be allowed to walk up stairs or out of the house. The essential factor is mental and physical rest. Lacarnol in doses of 20 drops a day has proved helpful. When freedom from attacks has been achieved for a fortnight, massage is invaluable. Walking should be resumed gradually. In venous congestive failure the treatment is rest in bed and adequate doses of digitalis. In urgent cases with vomiting, no more than glucose drinks may be tolerated, but otherwise milk may be given. Brandy is useful to control restlessness. overloading of the veins can be relieved by venesection, removing one-half to one pint of blood. If the liver is much enlarged six leeches should be applied over the organ. This diminishes the size of the liver and affords the patient much relief. The prognosis of edema is worse than that of The treatment consists in venous congestion. limiting the fluid intake and giving digitalis in doses of not less than one drachm a day. If the edema persists one of the xanthine group of diuretics should be added to the digitalis. Calcium diuretin in doses of 15 grains three times daily is safe and efficient. If no diuresis results within six days, salyrgan should be given intravenously. The diuresis following the use of this drug is usually prompt, but if it does not occur in twentyfour hours, ammonium chloride (20 grains three times daily) is given by mouth, and salyrgan is repeated after three days. Finally it may be necessary to draw off the fluid by Southey's tubes or multiple incisions down the shins. Quinidine is a valuable remedy in auricular fibrillation and flutter. It is dangerous, however in the presence of heart failure or of an active infection of the The most suitable cases are those with valve lesions, and thyrotoxic cases in which normal rhythm has not returned after thyroidectomy.

The Tame White Rat as Carrier of the Microbe of Weil's Disease (Spirochaeta ictero-

genes).—According to P. Uhlenhuth and E. Zimmermann, after the wild rat had been established as the carrier of the microbe of Weil's disease (Spirochaeta icterogenes), it seemed reasonable to assume that, in view of the close relationship, white rats as well as gray might be primarily infected with this microorganism. These authors accordingly made investigations in 33 tame white rats of 4 different breeds, first carrying out a serological test for antibodies with a typical Weil stock, and afterwards making a search for spirochetes by inoculating a liver-kid ney mixture into guinea pigs. It was not long before serologically positive animals were established; the titer lay mostly between 1:1000 and 1:5000, that is, decidedly high, and the antibodies of the rat serums had a thoroughly specific character, as revealed in a protective test in guineapigs with two rat serums. The examination for spirochetes was also successful. Of the 33 rats, 17, or 52 per cent, were serologically positive, and in 7, or about 21 per cent, the presence of spirochetes was confirmed by the guineapig test. Of these 7 white rats, 6 belonged in the serologically positive group, and only 1 in the serum-negative. Hence the actual number of spirochete carriers must evidently have been somewhat higher. It was next of interest to learn how these white rats had become carriers. Inquiry elicited the information that two of the breeds had earlier been caged with wild rats for breeding purposes, while this was not the case with the others. From these first two breeds 21 animals were born, of which 16 were serologically positive, and 6 were spirochete carriers. From the breeds not exposed to wild rats 12 animals were born of which only one was serologically-positive and two were spirochete carriers. It thus became perfectly evident that the infection came from the cages in which wild rats had been placed. Further experiments then revealed that it is rather difficult to infect white rats artificially so that they contract Weil's disease, but that when conditions were offered for infection in the natural way, the white rats responded equally with the wild gray rats, no difference being discernible. The experiments therefore prove that under appropriate conditions there is the same danger of infection of human beings from white rats as from gray. The case of a laboratory worker is cited, who after a severe bite from a white rat suffered with "an acute nephritis of unknown etiology," characterized by icterus, pains in the calves of the legs, and other symptoms of Weil's disease, over which, however, the kidney symptoms so predominated as to make an atypical picture. Serological examination later confirmed the authors' suspicion that this had been a case of Weil's disease, and that the patient had been infected with Spirochaeta icterogenes from the white rat bite.—Deutsche medizinische Wochenschrift, September 8, 1933.

LEGAL

MEDICAL TESTIMONY-LEGAL RIGHTS OF UNBORN CHILD

By Lorenz J Brosnan, Esq.
Counsel Medical Society of the State of New York

One of the Surrogates courts of this State recently was presented with a situation that should be of interest to every physician. The Surrogate was called upon to determine the legal rights of a child yet unborn at the date of the death of a person under whose will it was sought to permit the child to benefit

A certain woman died on May 22, 1922, having a considerable estate In her will she set up a trust for the benefit of her "grandchildren hving at the time of my decease" At the time of her death, there were four grandchildren who were born several years prior to her death, one the child of her daughter and the others, children of her two sons. On February 6, 1923, a period of eight months and fourteen days after the testatrix died, her daughter gave birth to another child Upon behalf of the said child, an application was made to the Surrogate to determine its rights under the In determining the matter a very well written opinion was rendered by the Surrogate The question of fact first considered was whether, if the child was in being on May 22, 1922, although yet unborn it was entitled to partake of the trust fund as "living" at the date of death. The court came to the conclusion that if the child was conceived prior to the death of the testatrix it was "living" on May 22, 1922 The word "hving' according to the Court has been defined as "having life, the state or quantity of being alive" Court made reference to a considerable mass of case authority from both the Courts of this country and of England, recognizing the principal that a child 'en ventre sa mere," as it has been called for many years, which is subsequently born alive, and capable of living may benefit under an estate as a "child living" Reference was made by the Court to the Real Property Law of the State which includes as a legislative enactment a recognition of the rights of posthumous children

Assuming then that such a child might be considered for legal purposes as "living" and therefore a possible beneficiary, the Court was under the necessity of determining whether the child was conceived prior to May 22 1922. The evidence submitted as to the fact situation was simple and apparently uncontradicted. At the date of the death of the testatrix her daughter was living with her husband at Santo

Domingo where he was stationed as an officer in the Marine Corps They were living under the same roof and occupied the same bed He was not absent overnight from their home between March 25, 1922 and May 25, 1922 On May 23rd a cablegram was received which in formed them of the death that had occurred, and on May 25th the decedent's daughter stilled to the United States leaving her hus band at Santo Donningo At that time she had passed her normal menstrual period by about ten days Certain testimony was sub mitted to the Surrogate given by the physician who later attended the child's mother during her pre-natal period, and at her delivery stated that he was consulted in September and was told that she had had her last menstrual period April 18th and had had a "showing' on April 30th He also testified that the woman's progress was normal and that from his obser vations the child was born at the end of a normal period of gestation. In support of that conclusion he testified

My ante partem examination records on January 9th 1923 show the diagnosis of a pregarate; of 8 months position of fetal heart normal, rate 140 vertex presentation and a right occiput interior position tending to show that the patient would be delivered in about one month from January 9th 1923"

The contention was advanced in opposition to the application that since conception could have taken place later than May 22, 1922, it was incumbent upon the petitioners to definitely establish an earlier date of conception, but the Court did not agree with that view The Court stated the rule to be applied as follows

'The respondents contend that as conception could have taken place after May 22 1922 if some of the medical theories could be proved correct the burden of proof to establish the faet of conception prior thereto has not been sustained by the petitioner A disputed medical theory impossible of proof is not evidence to rebut a presumption of law

There is a presumption that a child is conceived nine months or 280 days before its birth and when the child is a product of marital relations the presumption is that the conception came through intercourse by the hisband When no evidence is offered to rebut this presumption it becomes conclusive.

In summatizing certain theories advanced the court said

'Conception in its obstetric sense means the union of the male and female elements of procreation, from

which union a new being is developed. It is the means for the propogation of the human species.

The testimony of the medical expert offered by the respondents regarding the time of conception was to the effect that the medical profession is in a position of uncertainty, and its only recourse now is to guess at the exact date. The possibility that conception could have taken place later than May 22, 1922, is advanced by the respondents. Upon the doubt created by the medical expert, the respondents are relying to sustain their contention.

There are three theories as to the time when conception may take place. The medical expert testified that it was impossible to establish any absolute rule as to the length of the period of gestation; that there was a rule to count from the beginning of the last menstrual period, and that it varies anywhere from 252 to 260 days, from 265 to 280 days. The oldest theory is that ovulation occurred every month coincident with menstruation, and that the pregnancy supervened directly after menstruation; pregnancy being established the instant the menses did not appear. A newer theory of Reichert is that conception takes place prior to the menses that are coming, or that should come. Another theory by Frankel and other eminent physicians is that the cell from the woman is discharged from the ovary about 14 to 16 days after menstruation takes place. These three theories account for the variation of days as the period of gestation. Most text-books, the expert testified, will state the period of gestation, or when conception takes place is unknown, and has never been definitely proved, and is every man's theory.

Consequently, because of this indefiniteness in the medical profession, the courts fall back upon the ordinary length or duration of the period of human gestation of

280 days as a phenomena of life as a matter of common knowledge of which the courts will take judicial notice."

The Court, deciding to overrule the respondent's contentions, and to rule that this was one, so far as the proof went, where normal conditions had been present, also made reference to certain methods of determining the time of conception as follows:

"The Naegle method of ascertaining the probable date of birth is by counting back three months from the last menstrual period and add seven days. This method would bring the probable date of birth as it actually was, February 6, 1922.

Another method observed by the medical profession in ascertaining the date of conception and probable birth is noting the date of quickening. In the instant case, the quickening was September 11, 1922, as disclosed to the physician by the mother. The usual time for quickening to occur is four and one-half months from the date of conception. Dating back four and one-half months, or 135 days, from September 11, 1922, makes the date of conception May 1, 1922.

The medical expert was asked the questions: 'If it

The medical expert was asked the questions: 'If it is an established fact that quickening occurred September 11th, did conception take place four to four and a half months prior thereto?' Answer: 'Yes.'"

Consequently, the Court ruled from all the proof before it that the child was conceived on May 1, 1922, before the death of her grandmother, and was therefore entitled to share in the trust set up under the will.

CLAIMED NEGLIGENT DELIVERY

A general practitioner was asked by another doctor to attend and care for his patients while he went away from the City on a vacation.

Among those patients was a woman about 25 years of age, who was pregnant and due to deliver herself about two months later. The patient was examined several times at the doctor's office as to her physical condition and blood pressure and he advised her as to her diet and prenatal care.

At about 4 o'clock one morning about one month before the anticipated date of delivery the doctor received an urgent telephone call from the husband of the patient, telling him that his wife was having labor pains and that he was greatly worried. The doctor advised the husband to send her to a certain sanitarium where previous arrangements were made for her confinement. The doctor then called the sanitarium on the phone and asked the nurse in charge to notify him when the patient arrived in order that he might examine her. About an hour later he went to the hospital and did examine the patient. He found the position of the baby to be normal; the fetal heart regular and found that the woman was having pains every three or four minutes and that the cervix was about two fingers dilated. The doctor left the sanitarium, instructing the nurse on duty to call him when necessary. Pursuant to such call he arrived at the hospital again three hours later and found the patient on the delivery table having frequent pains and the head of the baby visible only during those pains. Because the patient was not fully dilated the doctor had time to remove his street clothes and prepare both the patient and himself for the delivery. Without any manipulation whatever he proceeded to deliver a small male child which he placed in a crib and then expelled the placenta, which took but a few moments. When he then turned to the baby he found there was no sign of life and proceeded in an attempt to revive the child, which was unsuccessful. In his attempt to revive the child he noted that the heart pulsation could be felt on the right side and not on the left and he diagnosed the child's condition to have been that of dextra cardia of congenital origin.

The mother had an uneventful recovery and left the hospital at the end of the usual period of time. An action was brought against the sanitarium and the doctor who delivered the patient, in which the claim was made that the sanitarium had represented to the patient and her husband that it had in its employ a successful and experienced obstetrician which it would supply to the patient

and that in reliance upon such representations the patient had entered said hospital and submitted herself to the care of the said sanitarium and its doctors, nurses and attendants; that the defendant sanitarium had failed to furnish the patient with proper care and treatment but on the contrary furnished the services of the defendant doctor and of a nurse, both of whom it was claimed were not competent to treat the case. It was claimed that by reason thereof the patient sustained injuries and the child was born smothered in the patient's womb. Both the doctor and

the sanitarium denied all allegations of negligence contained in the plaintiff's case.

The case came on for trial before a Judge and Jury and after all the evidence had been submitted the case was sent to the jury which, however, was unable to agree upon a verdict and a second trial was necessary. The case was thereafter retried and the issues were again submitted to the jury for its determination. On this occasion the jury returned a verdict in favor of both the doctor and the sanitarium, thereby favorably disposing of the matter.

ALLEGED NEGLIGENT TREATMENT OF FRACTURED FIBULA AND INTERNAL MALLEOLUS

A young man was struck by an automobile while crossing a highway and sustained a fractured leg. Certain treatment was rendered by a general practitioner who was immediately called to attend the patient, and some hours later the patient was taken to a nearby hospital and a specialist in surgery called into the case. The said doctor examined the patient and found that his foot and leg were in wooden splints. He removed them and found the ankle and the lower part of the leg extremely swollen. By manipulation the doctor found that the patient had a fracture of the lower portion of the fibula. X-rays were taken which showed a fracture of the fibula about three inches above the lower tip, and also a fracture of the in-ternal malleolus. The doctor placed the foot and leg in pillow splints and ordered the application of icebags.

The said treatment was continued for five days, at the end of which time the doctor determined that the swelling was sufficiently down for him to undertake to reduce the fracture. The doctor put the man under an anesthetic and forced the foot and broken fragment of the fibula inward against the tibia. The foot was then inverted, and while held in that position the doctor put a two-piece moulded plaster of Paris splint on the leg from the toes to the knee. He had x-rays taken through the splint which showed that the bones were in good position.

No change in the cast was necessary for about three weeks. When the doctor removed the cast, he found the bones in apparently good position. He then gave the patient passive motion of the ankle in all directions and found

motion to be good. He replaced the split cast on the foot for protection. By that time the patient was in a wheelchair.

The doctor saw the patient almost daily thereafter at the hospital for another month, and each time he saw the patient he removed the cast and massaged the foot. The doctor then, at the patient's request, transferred him to a sanitarium and recommended that he should submit to baking and massage treat-Several times thereafter the patient came to the doctor's office, and examination showed normal motion in all directions except a partial limitation of flexion. When the doctor last saw the patient about fourteen weeks after the injury, the patient stated that he was dissatisfied with the result and that he intended to go to a well-known orthopedist to have an operation performed. The doctor advised against such procedure, stating that he felt a satisfactory result would be obtained without the necessity of such surgical interference.

The next the doctor heard of the matter was when a lawsuit was instituted against him charging him with alleged malpractice in the treatment of the fracture. When the case was reached for trial in its regular order, the patient's attorney was not ready to proceed and the court directed that the case be marked off the calendar. Sometime thereafter the defendant's attorney made a motion to dismiss the complaint on the ground that the plaintiff had failed to diligently prosecute the case, and the plaintiff's attorney on being served with the papers for said motion consented to a discontinuance of the action.

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

The monthly meeting of the Committee on Public Relations of the Medical Society of the State of New York was held at Elizabethtown on October 24, 1933. There were present Doctors Sadlier, Fisher, Johnson, Hambrook, Mitchell, Cunningham, and Ross; also Dr. Farmer, Chairman of the Committee on Public Health and Graduate Education, and Executive Officer, Dr. Lawrence.

County Committees: The Secretary of the Committee was instructed to prepare a brief bulletin to be sent to each county medical society for the purpose of informing it about the work of the State Committee on Public Relations, and what was expected of its Public Relations Committee. The Committee also decided to promote the activities of the county committees by assigning its members to speak at the meetings of the county societies so that the state committee should be represented on the program of at least one meeting of each county society in the course of a year.

The Hard of Hearing: Doctor Hambrook for the sub-committee on hard-of-hearing, reported that the committee was at work on the problem of organizing a program to give better service in schools to the hard-of-hearing, and to provide that the schools should have the services of an otologist.

Welfare Department: The chairman reported that the joint letter of the chairmen of the Public Relations Committee and the Public Health Committee, and Doctor Howe of the Department of Education, sent out last year, had resulted in having a larger number of school children examined by their family physicians.

There was a discussion regarding the economic relation of physicians to the Welfare Departments of the State. A conclusion was reached that the Public Relations Committee should undertake to formulate a policy of the economic relationship of the profession to the administration of public welfare; and when this was formulated, to present it to the Executive Committee of the State Society. Doctors Mitchell, Sadlier, and Ross were appointed a sub-committee to formulate a statement of policy and report at the next meeting of the full committee.

Lectures to Medical Students: Subjects to be discussed in the lecture to the students of the Medical Schools of the State this year were taken up, and a conclusion was reached that ethics, economics, organization, and public relations were the most important. It was decided to have two members of the medical profession attend each lecture this year, each to speak for about two

minutes after the scheduled lecture in order to emphasize its salient features, and to show to the students that the profession of medicine is interested in their education.

Essex County: At the afternoon session, Doctor W. A. E. Cummings spoke for the Essex County Committee on Public Relations. He said that the Welfare work in the County was well done; that the health officer did much of the immunization of the school children against diphtheria; that the pre-school children were not immunized; and that the Society depended for publicity upon the activity of church organizations.

"The Essex County Medical Society decided not to adopt a fee scale for welfare work, and there is no complaint for lack of cooperation with the Welfare Department. A few hard-of-hearing children are found. Some of them are under treatment. There are seventy beds in the hospitals in the county, and a number of maternity homes. One township in Essex County with 6,000 population has spent this year for work relief \$217,000; but the State has reimbursed the township to the amount of \$115,000."

Franklin County: Doctor R. J. Perkins of Franklin County said that the physicians of the county society got up a fee scale at the request of the Board of Supervisors. It was practically the same as the fees in private practice. The county paid for medical care of the indigent in accordance with this fee scale until last year, and then the Supervisors asked the physicians to cut the fee scale because it was more expensive than the county could afford. The county society offered to take a cut of twenty-five per cent. The Board of Supervisors then gave the profession a fee schedule of their own, but the doctors insisted upon their former fee schedule.

The County of Franklin has two county nurses, but the doctors have asked for three. There are maternity clinics, a few pre-school clinics, and diphtheria clinics. Franklin County has a Public Health Committee made up of two nurses, three supervisors, and three physicians. The State District Health Officer takes an active part in the public health work. The County Medical Society is a leader in all health activities. Tuberculosis work is very well done. Every child in Saranac Lake and in Malone is x-rayed. Venereal disease clinics and well-baby clinics are held in Malone. These clinics are approved of by the County Medical Society. The county pays a doctor ten dollars for conducting each of these clinics.

W. H. Ross, Secretary.

SIXTH DISTRICT BRANCH

The twenty-seventh annual meeting of the Sixth District Branch of the Medical Society of the State of New York was held on Wednesday, October 8, 1933, in the Norwich Club House, Norwich, Chenango County, New York, with a registration of 119 physicians, and the President, Dr. Stnart B. Blakely, of Binghanton, presiding. Sessions were held in the morning and the afternoon, with a social luncheon at noon. The ladies of the members were entertained by a local group of the wives of physicians of Norwich.

At the election of officers, the two vicepresidents were moved up to the next higher offices, and the secretary and treasurer were re-elected. The complete set of officers elected

were:

President, Dr. John E. Wattenberg, Cortland.

First Vice-President, Dr. Leo P. Larkin, Ithaca.

Second Vice-President, Dr. Reeve Howland, Elmira.

Secretary, Dr. Hubert B. Marvin, Binghamton.

Treasurer, Dr. W. A. Moulton, Candor.

Two commercial exhibits were shown; pharmaceuticals by the Norwich Chemical Company; and instruments by Hamlin's Inc., Binghamton.

The scientific program was carried out as follows:

The Canti Movie Film, showing the behavior of living tissue cells on vitro, and the effect of radium on cancer cells. This film was in the 35 nm. size, and was loaned by the American Society for the Control of Can-

cer, and shown in the local theater by the courtesy of the management.

"The New Economic Philosophy applied to Medicine" was the subject of a paper by Dr. Frederic E. Elliott, Brooklyn, Chairman of the Committee on Economics of the State Society.

Dr. Frank C. Yeomans, New York, gave a paper on "Some Practical Points in Proctology," illustrated with lantern slides.

Dr. Thomas P. Farmer, Syracuse, read a

paner on "Uterine Bleeding."

Dr. Edward M. Livingston, New York City, gave a practical talk on "Aids to Precision in Bedside Diagnosis; a practical study and interpretation of Abdominal Pain, Rigidity, and Tenderness," illustrated with lantern slides and a moving picture showing the method of cliciting the signs. This was a repetition of Dr. Livingston's demonstration before the Third District Branch on September 5. (See this Journal, September 15, 1933, page 1120.)

The Sixth District Branch is located in the South Central part of the State, and is composed of the medical societies of nine counties

whose membership is as follows:

Broome	145	5
Chenango		3
Chemung	69)
Cortland	2-	1
Delaware	28	3
Otsego	50)
Schuyler	12	2
Tompkins	59)
Tioga	24	1

RELIEF OF QUARANTINED PERSONS

The enactment of the Public Welfare Law has given rise to some uncertainty as to who is responsible for the relief of a person quarantined for a communicable disease—whether the local Health District, or the Welfare of the town or county shall pay for the medical care and provide the necessities of life for the quarantined family. The State Attorney General has rendered an opinion which has the approval of the Departments of Social Welfare and of Health. The following outline of that opinion is designed to serve as a guide for the Welfare and Health officials of both the State and the local communities in determining their responsibilities in individual cases.

Definition of Indigency

An "indigent person" is one who is unable to maintain himself or the members of his family lawfully dependent on him for support; or one who ordinarily is able to maintain himself or his family, but because of his illness or the illness of some member of his family, or for any other reason, is, or becomes unable, to do so.

Class 1

Indigent persons for whom it would be necessary to provide care either at home or in a hospital irrespective of the quarantine by the health officer. Procedure: The health officer, when it comes to his attention that such a person is in need of maintenance, or of medical care either at home or in a hospital, and apparently unable to provide it for himself, should immediately report the facts to the proper public welfare official. From this point responsibility rests with the public welfare official for determining whether the person is in fact indigent and if so for providing necessary care

Class 2

Persons made indigent by reason of quarantine, as in case of a wage-earner, and requiring care either at home or in a hospital. This would apply, for example, to a situation in which the wage-earner, on whose wages he or the family depend for support, is himself the patient, or is prevented from working by a quarantine established on account of the illness of a member of his family.

Procedure: As in Class 1, the health officer should immediately report the facts to the proper public welfare official, stating the character and extent of the medical care which he believes to be necessary. From this point responsibility rests with the proper welfare official for determining whether the person is, in fact, indigent; and if so, for providing necessary care.

Class 3

Persons who are not indigent but who are financially able to pay, who are sent to a hospital, not upon their own option, but pursuant to a local ordinance or regulation, or to the order of the health officer.

Procedure: The health district should assume responsibility for payment of the cost of the necessary hospital care, and may subsequently take necessary steps to recover from the patient or those responsible for his support and care.

Class 4

Persons who need hospitalization, but about whom there is a question as to whether they are indigent, or will become indigent, as a result of quarantine.

Procedure: The question of the necessity of hospitalization should be decided solely by the health officer; and consequently the health district should be primarily responsible for the hospital bills in a case where hospitalization is necessary.

If in the judgment of the health officer the case is, or is apt to become, an indigent case, he should immediately notify, if in the city, the city commissioner of public welfare, or if in the county, the county commissioner of public welfare; and if subsequently such official decides that the person is, or has become, indigent, then the public welfare officer should assume the hospital expense from the date of indigency, thus relieving the health district of the expense.

If the public welfare official decides that the person is not, or has not been rendered indigent, then the original liability of the health district continues, and the hospital expense should be paid by the health district with the privilege, of course, of recovery, if possible, for such expense from the patient.

Class 5

Persons who are afflicted with a communicable disease and who are indigent, or become indigent, as a result of quarantine, but the individual does not require hospitalization for his own sickness, and the health officer hospitalizes the patient because of a local ordinance or for the protection of the public health.

Procedure: Responsibility for the expenses of hospitalization in this classification is upon the health district. The individual does not require hospitalization, and consequently is not a welfare charge; but he was hospitalized for the purpose of protecting the public health; and the expense for hospitalization is therefore obviously a charge against the health district.

Editorial Comment

Immediate action by health officers and physicians: When a communicable disease occurs in a family, or is strongly suspected, a responsibility for starting the machinery for action and relief rests upon the family physician and the local health officer.

The family physician is under obligation to report the case to the health officer promptly.

The health officer is under obligation to investigate the financial condition of the afflicted family, and to report its probable needs to both the Board of Health and the Welfare officer, thereby giving both agencies warning of impending conditions, and forestalling disputes and inefficiency of relief.

NEW YORK STATE SANITARY OFFICERS' ASSOCIATION

The twenty-third annual meeting of the New York State Sanitary Officers' Association was held in Syracuse on September 27, 1933. The annual meeting of the Association has heretofore been held at the time and place of the official Conference of Sanitary Officers called each year by the State Commissioner of Health, according to law and at the expense of the State and the local communities. This year the State Conference was not held on

account of the depression; the Sanitary Officers' Association therefore held its meeting independently, the health officers coming at their own expense to the number of about two hundred. Through the cooperation of Dr. William A. Howe, Chief of the Medical Inspection Burean of the State Department of Education, school physicians who are not also health officers were invited to participate. There were morning, afternoon, and evening sessions.

The morning session was devoted to a scientific program, with Dr. Myron M. Metz, First Vice-President of the Association, presiding.

Dr. George H. Ruhland, Commissioner of Health of Syracuse, welcomed the health officers in a brief address. He stressed the importance of the public health problem, increased because of present widespread economic distress.

Mr. Emmet R. Gaulin, Chief of the Department of Sanitation of Monroe County, gave a paper entitled, "The Importance of the Work of the Veterinarian in a Community Health Program." After discussing the beginning of the application of veterinary medicine to public health problems in the effort to cradicate tuberculosis from herds of dairy cattle, he discussed mastitis and contagious abortion in cattle, and rabies. He showed that the cooperation of the veterinarian was essential to the control of all of these diseases, which are menacing to human good health.

A paper on "The Immunization of Children Against Measles, Scarlet Fever and Other Infectious Diseases by Means of Parental Blood," was given by Dr. Frederick W. Sears, District State Health Officer, in which he emphasized the value of serum from adults in the prevention of serious symptoms in measles.

Dr. Charles G. Lenhart, of Rochester, read a paper on "The Relation of the General Surgeon to the Health Officer."

A paper entitled "Infections and Heart Disease" was read by Dr. O. W. H. Mitchell of the Syracuse College of Medicine. He limited his discussion to two types of infection, rheumatic fever, and subacute bacterial endocarditis. In discussing this paper, Dr. George H. Ruhland emphasized the importance of the distinction between the infectious type of heart disease, and the degenerative or senescent type.

The effect of the financial and economic crisis upon health conditions was discussed, and the proposed sixty million dollar ten year bond issue by the State to provide funds for unemployment relief was approved.

A motion was passed urging that the welfare laws should be redrafted so as to unify the various agencies at present administering the laws, and that such unification should be so effected that the administration will be under local officers who will be responsive to public opinion in the locality, and not subject to political considerations and influences.

The afternoon scientific discussion was concerned with health problems in relation to children and the schools. The general paper on "Childhood Tuberculosis" by Dr. William P. Brown, of the State Department of Education, distinguished sharply between the childhood predominantly glandular type of tuberculosis and the adult pulmonary type which might follow the former type. The discussion by Dr. James C. Walsh, Superintendent of the Jefferson County Tuberculosis Hospital, Dr. William J. Ryan, Superintendent of the Rockland County Tuberculosis Hospital, and Dr. Charles S. Prest, Secretary of the Queensboro Tuberculosis and Public Health Association, represented radically different points of view as to methods of dealing with the problem. Dr. Prest's discussion was especially interesting, for it was not intended to be a case-finding program, but a scientific research of the incidence and development of childhood tuberculosis and its possible development into the adult type.

The evening session was a dinner conference. The President of the Medical Society of the State of New York, Dr. Frederick H. Flaherty, gave an interesting address entitled "The Physician and the Health Officer."

Dr. Thomas Parran, Jr., State Commissioner of Health, followed with an address on Milk Control which was broadcast over the local N.B.C. station. Dr. Parran recounted the conditions which led up to the recent crisis in the milk industry and the necessity for its governmental regulation. He showed that regulation had already resulted in benefit to the producer, the distributor, and the consumer.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education of the State Medical Society, gave an address entitled "Some Plain Truths About Public Health."

The health officers of New York State form a group of over nine hundred practicing physicians, who are leaders in the public health movements of their localities. The great majority are active members of their county societies, and their voluntary attendance at the conference is evidence of their interest in their specialty.

GUY H. TURRELL, Secretary.

GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Sixth Annual Graduate Fortnight of the New York Academy of Medicine which was held during the two weeks of October 23 to November 10, 1933 was the largest and most successful of the series. The subject of the Fortnight was "Disorders of Metabolism" and included the whole range of metabolic conditions from allergy to vitamin deficiency, and from the common disorders such as diabetes to the newer phases of blood disorders.

The program was in three parts

1. Twenty afternoon clinics in fifteen hospitals.

2. Evening lectures in the main assembly room of the Academy building.

3. A scientific exhibit open throughout the day and evening.

Admission to the hospital clinics was by

ticket, and the demand was so great that the available room was taken before the opening of the Fortnight. About 125 subjects were listed for demonstration.

The evening lectures attracted audiences which filled the auditorium to overflowing. Twenty-one lecturers were listed, of whom nine were from other cities besides New York.

The exhibits that were listed numbered over one hundred, and consisted of charts, x-ray films, specimens, pieces of apparatus, and books. One had to study an exhibit or listen to the demonstrator in order to appreciate its full scope and significance.

The Fortnight gave the visitor a vivid impression of the immense amount of material for graduate instruction that is available in

New York City.

ONEIDA COUNTY

The regular quarterly meeting of the Oneida County Medical Society was held at the Oneida County Hospital at Rome on Tuesday, October 10, 1933, following a splendid lunch provided by the Superintendent and Board of Managers of the Hospital.

Dr. W. B. Roemer for the Board of Censors presented the following applications for mem-

bership, and they were duly elected:

Edgar O. Boggs, Boonville, New York. Arthur F. Gaffney, Oriskany Falls, N. Y. Karl W. Gruppe, 258 Genesee Street, Utica, N. Y. Vito S. Lee, 654 Bleecker Street, Utica, N. Y. Radford C. Tanzer, 258 Genesee St., Utica, N. Y.

Secretary Hale announced that he had reported to the Investigating Committee of the State authorities regarding illegal practices by an Indian Medicine man in Rome, and two health concerns in Utica. This brought a query as to whether osteopaths might write prescriptions, and to the suggestion that the State Department of Education be notified of the facts.

Dr. 11. H. Shaw spoke of an investigation followed by conviction, of a case of illegal practice at the city court a few months ago.

Dr. T. Wood Clarke offered the following resolution on the occasion of the honor accorded to one of our members:

Whereas: A member of the Medical Society of the County of Oneida has recently received from the sovereign of his native country a distinguished honor, in that he has been knighted by King Vietor Emmanuel III and has been awarded the title of Cavaliere of the Order of the Crown of Italy, and

Whereas: This honor has been conferred upon this member of our Society in recognition of his unselfish and unremitting labors during a quarter of a eentury for the betterment of the Italian population of the City of Utica and the County of Oneida; therefore he it

therefore be it Resolved: That the Medical Society of the County of Oneida formally expresses its appreciation of this honor conferred upon its distinguished member, and extends its most hearty congratulations and fervent good wishes to the recipient of this well deserved recognition, Cavaliere Doctor F. John Rossi.

The President, Dr. B. P. Allen, introduced as speaker of the day, Dr. Walter L. Machemer, Surgeon at the University of Buffalo Medical School, who spoke on "Diseases of the Breast." This paper was discussed by Doctors Shaw, Boggs, Allen, Powers and Golly.

The Society adopted memorials of Dr. D. C. Broga of Rome and Dr. C. R. Barlett, of

Boonville.

The program of the meeting was printed in the style and language of Rome, both ancient and modern. The menu was headed "Index Ciborum," and began with "Olivæ Iberici," and ended with "Potus, Liquor Fortis and Liquor Mitis."

There were also three pages of quotations, beginning with one from Psalm 133: "Ecce quam bonum jucundum habitare frates in unum," and ending with the following in ultra modern Roman, ascribed to one of the physicians of Rome: "I have, by actual test, proven to my own satisfaction that a Buick, while a good car on land, is very unsatisfactory as a hydroplane. I was all wet on that subject."

WILLIAM HALL, JR., Secretary.

SUFFOLK COUNTY

The 127th Annual meeting of the Suffolk County Medical Society was held on October 26, 1933, in the Henry Perkins Hotel, Riverhead, N. Y., with 60 members present and the President, Dr. L. F. Garben, presiding. Morning and afternoon sessions were held with a social luncheon between.

Officers were elected as follows:

President, Morley B. Lewis, Sag Harbor. Vice-President, Wilbur C. Travis, Northport.

Secretary, Edwin P. Kolb, Holtsville. Treasurer, Grover A. Silliman, Sayville.

Censors, W. H. Barnhardt, Central Islip; B. P. MacLean, Huntington; Paul Nugent, East Hampton.

Delegates to State Society, L. F. Garben, Islip;

Albert E. Payne, Riverhead.

Alternates, Guy H. Turrell. Smith Branch; Frederick S. Child, Port Jefferson. Smithtown

Member of Executive Committee of the Second District Branch, W. H. Ross, Brentwood.

New Members elected were: Louis F. Foster, Center Moriches. Morris Chesanow. East Islip. William Holmes Ross, Patchogue. Frank P. Holmberg, Sag Harbor.

Dr. L. F. Garben reported on the formation of an arbitration committee to adjudicate workmen's compensation cases after the plan of the committee in New York County. There was considerable discussion over the details of the agreements with the insurance carriers, some members urging that definite fees and fixed conditions be adopted. The concensus of opinion was that since the committee was formed for the purpose of arbitration, it should be guided by general principles rather than fixed rules.

Dr. W. H. Ross for the Economic Committee urged the need for more constructive planning by the members to meet the developing conditions in economics, especially in the relation of the physicians to the Department of Welfare, and the officials engaged in Workmen's Compensation.

Dr. L. F. Garben gave the annual presidential address, making suggestions regarding the work of the Society. These suggestions were referred to the Comitia Minora.

Dr. Louis A. VanKleeck, President of the Second District Branch, gave a brief address outlining a plan for united action by the four county societies on Long Island. He referred to the prospect of a grant of money for the purpose of promoting the unification of all public health activities in the counties. Long Island is a field peculiarly fitted for the demonstration, since it has a population of about three million people who are set apart by water boundaries, and who represent every type of political organization from the intensely urban to the strictly rural.

Dr. Alee N. Thomson, Secretary of the Second District Branch, outlined the plans for the meet-

ing on November 16 in Garden City.

Dr. E. M. Livingston, of New York City, gave an address on the subject "Abdominal Pain-Its Relation to Tenderness, Hyperalgesia, and Abdominal Rigidity," illustrated with lantern slides and moving pictures. The address was an interpretation of the character and location of the signs and symptoms which are dependent on the origin and distribution of the nerves of the abdomen. This distribution of nerves is a valuable diagnostic key which a physician may apply at the bedside with accurate results.

EDWIN P. KOLB, Secretary.

LIVINGSTON COUNTY

The annual meeting of the Livingston County Medical Society was held at the Big Tree Inn, Genesco, N.Y. on Wednesday evening October 11, at 6.30 p.m.

The following officers were elected for the year 1934:

President, L. A. Damon, Sonyea, N. Y.; Vice-President, Homer Bull, Geneseo, N. Y.; Secretary-Treasurer, George Doolittle, Sonyea, N. Y.; Delegate to State Society, Gerald Murphy, Mount Morris, N. Y.; Censors, Drs. Preston, Burt, Newton, Shanahan and Swan.

Drs. Robert F. Lewis and Harold Morris

Sessen of Lima, and Christian E. Laatsch of Sonyea, were elected to membership.

A memorial was adopted on the death of our oldest member, Dr. W. E. Lauderdale of Geneseo.

An address on the more common skin diseases was given by Dr. Earl D. Osborne of Buffalo, N. Y. Dr. Osborne's presentation included the diagnosis and treatment of ringworm, acne, psoriasis and eczema. The paper was fully illustrated with excellent lantern slides and was freely discussed.

GEORGE M. DOOLITTLE, Secretary.

BOOK REVIEWS

AN ELEMENTARY HANDBOOK ON RADIUM AND ITS CLINICAL USE. By D. F. CLEPHAN and H. M. HILL. 12mo of 164 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$2.00. (Oxford Medical Publications.)

Miss Clephan has been associated with the work on radium therapy at the Middlesex Hospital for many years; and Mrs. Hill, as Radium Officer at the Royal Free Hospital, has had first hand experience in modern methods of treatment.

This little handbook is not as elementary as its title would indicate, and it serves the purpose as a general introduction to a more advanced study of the subject.

The book gives some of the landmarks in the history of radium therapy and a short description of radio-activity and radioactive elements. The authors are very clear in their remarks on the practical considerations in the use and care of radium and radon, as well as in their discussion of the fundamental and general principles of radium therapy.

An excellent description is given of the methods employed in the application of radium in the treatment of special portions of the body, and the complications and contra-indications of the therapy are thoroughly covered.

The concluding chapter contains an excellent discussion of the present position of radium therapy in the treatment of malignant disease.

The volume is very much worth while for the student, and for those who wish to get a quick and accurate glimpse of the subject.

W. Sidney Smith.

THE ELEMENTS OF MEDICAL TREATMENT. By ROBERT HUTCHISON, M.D. Second Edition. 12mo of 188 pages. Baltimorc, William Wood & Company, 1933. Cloth, \$2.00.

Reviewing this little book on therapy has been a decided treat. It has been found highly practical and will prove of great value. Its practicability and value lie in its simple, concise language, its many worthwhile suggestions and the ease with which these suggestions can be carried out.

The treatment of fever, pain, insomnia, constipation, diarrhea, heart failure, bronchitis, anemia, high blood pressure, urinary infections, dyspepsia, intestinal parasites, diseases of the gall-bladder, nephritis, hemorrhage, tonics, diabetes are discussed. The article on endocrine treatment leaves much to be desired, but the discussion of the use of vaccines, serum, physiotherapy and psychotherapy are excellent.

Of decided value are the descriptions of several minor medical operations such as blood transfusion, subcutaneous infusion of saline, intraperitoneal injection of saline, rectal saline, paracentesis of the pleura, pericardium and peritoneum, spinal puncture, vein puncture, intravenous medication, cupping and the application of leeches.

M. A. RABINOWITZ.

Abortion: Legal or Illegal? By A. J. Rongy, M.D. 12mo of 212 pages. New York, The Vanguard Press, 1933. Cloth, \$2.00.

In this well written book with a catchy title the author wishes broadening the legal ground for abortion. Mother Church and Bible toters are thoroughly taken into camp. The warp and woof of his argument is that, according to his guess, over 2,000,000 abortions are done every year in this country. Why not legalize them? More

and better abortions. Many women go to New York and Chicago, where the abortionists reap a golden harvest of over a hundred million dollars a year. The author is not quite clear here—possibly this is the national figure. One wonders where he gets his figures. The tax gatherer should be interested, for Wilbur's Committee found that one-half of the country's physicians were saving \$3,800 a year or less. Legal abortion would undoubtedly distribute its rewards more evenly. Infanticide in selected cases should pay well. Lately we have been told that illegal abortion in Russia is about as common as it ever was. If this be true, let us make the most of it.

Charles A. Gordon.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Ycar's Progress in Medicine and Surgery. Series 1932. Chicago, The Year Book Publishers [c. 1933]. Neurology, edited by Peter Bassoe, M.D., and Psychiatry, edited by Franklin G. Ebaugh, M.D. 12mo of 488 pages, illustrated. Cloth, \$2.25.

This book is a review of the more important contributions in the field of neurology and psychiatry during 1932. There are several articles on epilepsy. Head injuries are discussed from the standpoint of mechanisms, encephalographic observations and complications. Disseminated encephalo-myclitis, multiple sclerosis, and Schilder's disease are grouped as diseases belonging to a form of non-suppurative infectious encephalo-myclitis. Two articles by Cushing are of utmost importance; one being a description of the clinical picture of basophilic adenoma of the hypophysis and the other on the relationship of brain lesions to gastric ulcer.

In the division on pyschiatry, there is an article on "The crisis in psychiatric education," in which psychiatric teaching in the medical schools of the country is reviewed. There are also articles on the relationship of psychiatry to pediatrics and finally discussions on mental deficiency and mental hygiene.

STANLEY S. LAMM.

UROLOGY IN WOMEN. A Handbook of Urinary Diseases in the Female Sex. By E. CATHERINE LEWIS, M.S. Octavo of 76 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$2.25.

This little book of seventy-six pages is an up-to-date, concise compendium of the diseases of the female urethra and bladder. A small section is devoted to a consideration of a very limited number of lesions of the ureter and kidney. The treatment of each condition is outlined in each instance. While the work is more appropriate for the student, the urologist and gynecologist would do well to review it, particularly the consideration of the female urethra. The book is well illustrated. The references, however, are limited.

Augustus Harris.

THE PRINCIPLES OF TREATMENT OF MUSCLES AND JOINTS BY GRADUATED MUSCULAR CONTRACTIONS. By MORTON SMART, M.D. Octavo of 217 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$3.75. (Oxford Medical Publications.)

This book covers the author's thirty years' experience in the treatment of Muscle disabilities by controlled muscular exercises produced by electric stimulation. The work covers much more than the title implies. It gives an excellent résumé of the normal physiology of joints and muscle action, as well as the acute and chronic pathology resulting from joints and muscle

injuries. Muscle mechanics are also carefully considered.

The use of electric stimulation to produce muscle contractions has received very little attention from the profession except from a comparatively few interested individuals. If this book is carefully studied and directions followed, it will put this method of treatment nuch more in use, as it deserves to he. An apparatus to produce graduated nuscular contractions devised by the author is described in detail.

If a new edition should be published it could be improved by the inclusion of illustrations, the lack of which makes the present edition rather difficult reading.

The book will be a very valuable addition to the library of any physician interested in traumatic surgery, as well as to the Obstetrician for its use in treating weakened abdominal muscles after pregnancy.

Joseph B. L'Episcopo.

ELEMENTS OF ELECTROCARDIOGRAPHIC INTERPRETATION, By LOUIS N. KATZ, M.D., and VICTOR JOHNSON, Ph.D. Octavo of 38 pages. illustrated. Chicago, The University of Clicago Press [c. 1932]. Paper, \$1.00.

This is a small, inexpensive, pamphlet which is devised for the needs of the student and the physician whose specialty lies outside the field of electrocardiography.

It describes the common deviations from the normal electrocardiogram clearly and conciscly, each deviation being demonstrated by illustrations of actual electrocardiograms. These illustrations are clear and easy to interpret because of the clear descriptions that are attached to each tracing. This, in our impression, fulfills the need for which it was compiled.

ARTHUR E. LAMB.

MINOR SURGERY. By FREDERICK CHRISTOFHER, M.D. Second edition. Octavo of 998 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$10.00.

This book gives a cross-section of surgical practice that exceeds the average concept of Minor Surgery. It gives many excellent suggestimns to be used in major surgical problems and covers the field of so-called minor surgery in a very complete and descriptive manner. The illustrations are excellent and the operative procedures are very painstakingly presented. The Bibliography is extensive. I feel that this book can very fittingly be added to the library of any Doctor and might easily be considered indispensable to the general practitioner.

Environ J. Grace.

THE COMMON CAUSES OF CHRONIC INDIGESTION, Differential Diagnosis and Treatment, By THOMAS C. HUNT, M.D. 12mo of 341 pages, illustrated, Baltimore, William Wood & Company, 1933. Cloth, \$4.25.

In this monograph, the author has approached the problem in a practical manner. Most of the details of specialized laboratory and x-ray investigations have been omitted and more stress has been placed on the clinical aspects of Indigestion.

The book has been written by one who has had a great deal of experience with patients presenting digestive disorders. The chapters an indigestion in old age and the cardio-vuscular system and indigestion bear tribute to the practical aspects which the author at all times rightfully considers of the greatest importance.

The functional and organic disorders responsible for symptoms are thoroughly discussed and at the end of the book, the practitioner will find useful information of the methods of investigation, case taking and prescriptions.

The book can be recommended to the physician doing general practice. IRVING GRAY.

DIET IN SINUS INFECTIONS AND COLDS. By EGON V. ULLMANN, M.D. Octavo of 166 pages. New York, The Macmillan Company, 1933. Cloth, \$2.00.

"Diet in Sinus Infections and Colds" is a valuable book written to be readily understood by those of the lay folks with a general knowledge of biochemistry and an interest in diet scientifically controlled. It is of great value to the physician whose dictary and related biochemical knowledge needs freshening or support. The detail of food, its proper preparation and end result are all carefully and clearly set forth and numerous balanced menus with recipes are given. The practical difficulty in appreciating this work is in following the detail, which only the most interested patient could be depended upon to do.

The experience of the author as well as many others as established the value of diet in upper respiratory infections conditions, both as a prophylaxis and in treatment. Here we have set forth the usual causes of cilihrer of dietary regimen and how to avoid them, as well as many general comments in dietary faults worth everyone's attention. The book is well written and casy to read.

CHARLES R. WEETH.

THE HEROIC AGE OF SCIENCE. The Couception, Ideals and Methods of Science Among the Ameient Greeks. By WILLIAM A. HEIDEL. Octavo of 203 pages. Baltimore, Williams & Wilkins Company, 1933. Cloth, \$2.50. (Published for Caruegie Institution of Washington.)

Professor Heidel has written a delightful "booklet," in which he champins the "Ancient Greeks" in their conceptions, ideals and methods of science. He limbts a strong brief for their genius, mental agility and powers of observation in all of the departments of cognation; and stresses the lact that they were pioneers in observation and induction, classification, analogy and experimentation. He urges that such master-minds as Hippocrates, Aristotle, Plato, Archimedes and all the rest set the pattern, for all time, for method in scientific procedure and ascribes error in technique to paucity of apparatus, such as the microscope and other instruments of precision of our day, as well as an unavoidable lack of knowledge of chemistry. The book is the product of a profound scholar, and is replete with quotations from the original Greek, illustrating the mode of thought and action of the ancient Maestro. It is a cultural contribution to the history of science, including medicine, and a choice addition to any library.

L. M. VAN COTT.

A SHORTER ORTHOFEDIC SUBGERY. By R. BROOKE, M.D. Octavo of 150 pages, illustrated. New York, William Wood & Company, 1932. Cloth, \$3.75.

It is a scrious question if a Shorter Orthopedie Surgery acommplishes anything—it is neither fish, flesh nor fowl. It is neither a quiz compend nor a text on the subject and is very prone to give the student a false conception of the subject. Furthermore the book does not seem to be very well balanced, as fully four pages are devoted to the cervical rib, a not too common condition, whereas only one short paragraph is given to osteparathritis of the hip, a condition much net with.

The makeup of the book is excellent and the photographs are good. It would seem that not only movie actors and diplomats must always smile when photographed but also cripples, when carrying around on their backs pounds of plaster of Paris. Now I know of nothing in a plaster of Paris jacket to make anyone smile.

I agree fully that the standard textbook in Orthopedic Surgery has become a massive tome but I do not think that the subject can be covered even briefly in the one hundred and fifty pages that go to make up this volume.

JA. C. RUSIMORE.

OUR NEIGHBORS

MEDICAL CHARITY IN WEST VIRGINIA

The October number of the West Virginia Medical Journal contains the following editorial comments on medical charity:

"Why should medical charity be dispensed on a different basis than other commodities? All the people, including the doctors, contribute to a common fund through taxation to provide food and clothing. But medical treatment is still saddled onto the doctor and he must make the most of it. It does not seem at all fair.

"Five years ago, when times were good, we heard little about medical charity. That was because there was little medical charity work to do, and it was handled by the medical profession with little trouble and less credit. Today, when we have millions on the roster of unemployed, the problem becomes a proposition of staggering proportions because the doctors have had less and less pay work and more and more charity work. Now, at long last, the medical profession is beginning to make itself heard. In many states, including West Virginia, a schedule of allowances has been adopted for doctors attending charity pa-This fee schedule is approximately one-half the amount generally charged in rural sections. In other words, it is better than nothing. At least it is supposed to be.

"Let us look at the general plan of medical practice as it has been handed down to us

over a period of several hundred years. Under that plan we have charged our patients just about what we thought they were able to pay. The excessively rich have paid thousands of dollars for the same operation that would cost a laboring man less than a hundred. Well-todo business and office executives have been called on for much higher fees than clerks and carpenters and butchers. This plan, tried out by untold generations of medical men, has been remarkably successful. It has pleased the doctor and has pleased the doctor's patients. It has become so much a part of medical economics that the plan has been recognized time and time again by the courts throughout this country. The doctors have prospered under this plan, and, until a few short years ago, they have been glad to follow it.

"The doctors asked for some relief from the great burden of medical charity. In making that request, it seems to us that they implied a willingness to throw overboard their timetried system of charging according to the incomes of their patients. There is only one justification for charging high fees against the rich. That justification is found in the free work that is given to the poor. Once the doctors start collecting for their poor work, there is no longer any justification for the marked difference in the charges."

MOTION PICTURE EXHIBIT IN THE PENNSYLVANIA ANNUAL MEETING

The announcements of the features of the Annual Meeting of the Medical Society of the State of Pennsylvania on October 2-5, is contained in the September issue of the *Pennsylvania Medical Journal* which describes a proposed motion picture exhibit as follows:

"At least 20 films will be projected. In keeping with the established policy of the Society in the make-up of its programs, every interest will be served so that the man engaged in general medical work will find considerable to engage his attention, and those devoting their time to highly specialized lines will suffer no neglect. Those physicians engaged in general work who are at times compelled to function as specialists in their respective communities will here find opportunity to refresh their tech-

nic of examination and perhaps amplify their therapeutics. The practical aspect of medicine will be emphasized in every respect. As in the case of the Scientific Exhibit, the effort has been made to correlate the motion pictures with the subjects covered in papers by authors appearing before the various sections. films will be arranged in such a manner that they will be shown in the morning preceding the presentation of the same subject in the afternoon before the sections, in the formal essays. For example, motion picture films on cardiology will be exhibited on Tuesday morning; the papers on this subject will be read on the afternoon of the same day in the Section on Medicine. A motion picture film relating

to the treatment of strabismus will be shown on Thursday morning, and on the afternoon of the same day, H. Maxwell Langdon will read a paper on this subject before the Section on Pediatrics. While the purpose of the photographic review is primarily to refresh latent knowledge on the particular subject, it serves the additional purpose of creating a degree of scientific curiosity that makes for more extended inquires along this same line, and the objective of all education is indirectly attained. It is anticipated that requests may also reach the committee for a repetition of the showing of these films after the papers as well as before, and if feasible this will be done.

"There will also be a most comprehensive series of motion pictures illustrating electrocardiographic tracings which are correlated with animated motion pictures of the heart and valve action. Though this is of outstanding interest as an isolated display, the additional feature that is coordinated with the scientific exhibit of the Philadelphia Heart Association and the formal papers to be read on the subject of coronary disease, makes it unique in the field of such exhibits."

Moving pictures have been shown in connection with the scientific exhibit for the past two

years with increasing interest and success. This feature is described in a personal letter from Dr. Walter F. Donaldson, Secretary of the Medical Society of the State of Pennsylvania, as follows:

"The picture theater immediately adjoining the scientific exhibit is made attractive to members by fixing definitely in advance the time for showing certain pictures and providing facilities for request repeats of pictures. At our 1931 session we had a registered nurse in full uniform during exhibit hours at the door of the theater, writing on a blackboard the name of the picture and keeping a definite record of the attendance upon each picture. During the 1932 session we did not have the nurse, but instead a uniformed policeman, who excluded from the theater as well as from the scientific exhibit those not wearing our official registration button. This year we had both policeman and nurse.

"The average attendance upon the twelve pictures shown on Thursday of the 1933 session was 49 per picture. The attendance upon the various pictures shown throughout the three days averaged 39, ranging from 5 to 65. The most popular pictures were 'Experimental Studies in Blood Coagulation,' 'Plastic Surgery,' 'Breech Extraction,' and a group of cardiocirculatory pictures.

It was noted that the attendance throughout the

CURITY has used and Curity is using X-Ray Diffraction technique, not as a manufacturing process, but as a method of research on catgut structure, to enable improvement of the processes used in the manufacture of surgical sutures.

Revealing as it does, for the first time, the cell alignment of unprocessed catgut, this X-Ray research has made available to Curity scientists facts which have enabled them more intelligently and more accurately to govern eatgut processing, and to definitely improve the treatment of eatgut to accomplish certain results.

Specifically, X-Ray Diffraction technique offers these two main advantages in Curity's manufacturing procedure:

- It gives us more data than has ever before been available concerning the structure of catgut and its behavior under any given condutions... This knowledge is of immense general benefit in the production of a thoroughly dependable product
- 2. Specifically it forms a basis for analysis and improvement of our manufacturing processes.

Manufacturing skill in the production of sutures has reached a high degree of perfection. To this, Curity Laboratories add actual results of X-Ray Diffraction Research in the production of Curity Sutures.

(Continued from page 1356—adv. xii) various scientific exhibits was greatest where the zeal of the demonstrator was most marked.

"If called upon to give the requisites for a successful scientific exhibit, and moving and sound picture theater, I would suggest the following, in the order of their importance:

"1. Sufficient funds to furnish adequate space and facilities, without material expense to exhibitors.

"2. An ardent chairman with good judgment.

"3. Exhibits by men and women who are 'zealots' in their chosen subject. This assures devoted demonstrators who will not only answer questions helpfully, but will buttonhole the passersby.

"4. Correlation between the Committees in charge of the various sections of the scientific program. This year twenty-five per cent of our scientific exhibits were thus related to papers and discussions. This should apply to pictures shown as well as other diagnostic or therapeutic demonstrations."

THE MAINE MEDICAL JOURNAL

Some unique reasons for the existence of the Maine Medical Journal are given in the following extracts from its October issue:

"All writings have as their functions the recording and communication of thought and experiences, and unless a state membership can by any stretch of imagination declare itself sufficiently sterile in thought and experiences, no one can question the value of their recording and their intercommunications.

"A true criticism may be made, to the effect that too few of our members are not sufficiently articulate and lack the experience in medical writings. This argument is a most powerful one favoring the maintenance of a journal towards the development of that highly-prized and valued art.

"To amalgamate with any other periodical is too facile a course and will lead to over stagnation. By virtue of our own Journal only can our membership be stimulated to develop the art and science of medical writing.

"The problem is primarily one of self-education and stimulation toward the development of a talent undoubtedly present, though latent, among our members in the art of creative medical expression. The experiences of a fellow practitioner in this state are of more interest to us than the experiences of men elsewhere.

"Our state membership typifies the general practitioner, whom we are again beginning to appreciate as forming the bed-rock of medical practice. Ours is the opportunity and duty to further that recognition by transplanting his experiences and incorporating them into the much-needed and well-merited place in medical literature. Our Journal is the instrument towards its development and perfection."

OFISHY TRISTE because they contain the PALATABLE

FRUIT and VEGETABLE FORM OF VITAMIN A

CARITOL, for A, alone-

Caritol is a 0.3% solution of Carotene (C, H,), the table form of vitamin A. and therefore represents the

form in which most vitamin A is naturally consumed by the human body.

Helps Build Resistance and Promotes Growth

Caritol, by virtue of its vitamin A activity, promotes growth and, as indicated by experimental studies, may be an aid toward the establishment of resistance of the body to infections in general. It may be prescribed alone or with CAPSULES OR DROPS other vitamin products. There is INSTEAD OF no fishy taste or bad after-taste. The TEASPOONS cost is reasonable, too. Caritol is available in 15 c.c. and 50 c.c. EASY DOSES dropper-top bottles and in capsules packed 25 and 50 to the box.

CARITOL-with-Vitamin D

Caritol-with-Vitamin D is ation of vitamins A and D the most palatable combinon the market because it contains the fruit and vege-

table form of vitamin A, carotene, and a tasteless vitamin D prepared for therapeutic use by methods (Zucker process) developed at Columbia University. It is naturally palatable, not artificially flavored.

For A and D, together in Palatable Form

Caritol - with - Vitamin D is, therefore, especially recommended for patients who need both vitamins A and D, but object to the fishy taste of fish liver oils and their concentrates.

> There is no fishy taste or bad aftertaste, and the cost is reasonable. Available at prescription pharmacies in 5 c.c. and 50 c.c. dropper-top bottles and in 25-capsule boxes.

Prescribe these naturally palatable vitamin products - they cost no more.

Taste the carotene products yourself. Write for samples. We also offer Smaco Cod Liver Oil fortified with carotene and vitamin D for those physicians who prefer to prescribe cod liver oil. It is three times as potent in both vitamins A and D. Therefore one teaspoon is equivalent to three teaspoons of good grade cod liver oil. Improved flavor and minimum cost to patient. For vitamin Dalone (for the prevention or cure of rickets), we offer Smaco Vitamin D, a highly potent extract of the antirachitic principle of cod liver oil prepared by methods (Zucker process) developed at Columbia University. Ten drops equivalent in vitamin D potency to three teaspoons of good grade cod liver oil.

MATERNAL CARE IN PITTSBURGH

The Medical Society of the County of Allegeheny, Pa., in which the City of Pittsburgh is located, has sent the following notice to its members:

"Attached is a copy of the Plan of Operation of the Public Relations Auxiliary Committee on Maternal Care, for the execution of which the Council of the City of Pittsburgh has appropriated \$50,000. Since the plan becomes effective immediately, it is important that you acquaint yourself at once with its provisions.

"You will note that the plan applies only to residents of Pittsburgh who are on relief. Attending physicians, however, may reside be-

yond the city limits.

"Patients should procure from the Alleglieny County Emergency Association, City-County Building, a printed form executed in duplicate, both copies of which should be presented to you during the first or second visit. The signed copy is to be forwarded to the above Committee together with the medical history of the case and formal bill for \$25."

The plan is outlined as follows:

"The members of the Allegheny County Medical Society agree to render to the expectant mother adequate medical supervision during her pregnancy, labor, and puerperal period, including the baby after its birth, under the following conditions:

"All duly qualified and registered physicians residing and practicing medicine in Allegheny County shall be entitled to participate in this plan and the remuneration unless later re-

moved for cause,

"The patient shall have a free choice of

physician or hospital.

"At the time of the first contact between the physician and patient the physician shall make a thorough physicial examination of the patient including a pelvic examination, pelvic measurements, Wassermann (or Kahn) and a blood count when necessary.

"The physician shall instruct and insist upon the patient making monthly calls during the first months of her pregnancy, bimonthly during the seventh month and weekly during

the eighth and ninth months.

"The physician shall respond promptly when the patient goes into labor and spend sufficient time with her watching the progress of labor and the welfare of the infant to insure the patient's safety. If complications develop, he may have any patient removed to the hospital of his selection under specified conditions.

"After delivery the case shall be reported to a visiting nurse service. The nurse responding to the call shall follow the orders left by the

The physician shall be responsible for a proper record of the puerperal period.

"At the end of the puerperal period the physician must insist upon the patient calling at his office, when any treatment necessary shall be given and her condition recorded."

"Upon completion of the case (about six weeks after delivery), the attending physician shall submit the entire case history to the Public Relations Auxiliary Committee on Maternal Care. If the history is approved, recommendation for payment will be made to the Controller of the City of Pittsburgh. Payment will not be recommended when for any reason the entire service and history are not considered satisfactory by this committee.

"The plan outlined above shall apply also to hospitals, the patient going to the hospital

of her selection.

"If a complicated case is referred to the hospital when in labor the compensation shall be divided as follows; 60 per cent (attending staff physician not participating); the 40 per cent shall go to the physician submitting satisfactory evidence of proper prenatal care."

RELIEF AND PREVENTIVE MEDICINE IN TENNESSEE

Commenting on the comparative value of medical relief to the poor, and preventive medicine, the October Journal of the Tennessee State Medical Association says editorially:

"Some counties in which the economic conditions are bad have appropriated money out of the county treasury to support so-called county units. Certainly a county health unit properly organized and directed may be capable of rendering worthwhile service if it can be afforded.

"At the present time a majority of the work of these units consists of the administration of immunizing treatments to prevent smallpox, typhoid and diphtheria; making some school inspections; in carrying on a minor amount of sanitary work and in carrying on a considerable amount of publicity work.

"The relative importance of these activities can be overestimated and oversold and their

costs can be multiplied enormously.

"The administration of typhoid vaccine to an entire country school requires little time: Very slight overhead expense and no more skill than is required to administer a hypodermic injection of any kind. This particular activity, however, lends itself beautifully to (Continued on page 1363—adv. rix)

(Continued from page 1362-adv. xviii) the purposes of publicity. The entire time, expense and skill involved in giving such reatment to an entire school would not be equal in many instances to the time, skill and expense required to give proper attention to an ndigent woman in confinement in the same community by the local general practitioner The latter activity does not lend itself to the purposes of publicity. Relatively few people will know anything about the incident. The practitioner, of course, has no publicity bureau

to prepare articles for the county newspapers

"The doctor in charge of a local health unit

draws his salary from the state. For these times it is a high salary. The state defrays the cost of his transportation. The state pays his office rent and the state pays for his office help.

"There is not a graduate practitioner in the state who is not perfectly capable of administering any of the several vaccines and sera for the prevention of these various diseases If the practitioners were paid a reasonable sum for these activities this income would help defray their office expenses and help them get by in this crisis Such a plan is being carried out in at least one state with efficiency and economy"

HOW PHYSICIANS BENEFIT FROM MADE-TO-ORDER WEATHER

Air-conditioning has, for many years, made possible the production of Lilly capsules every working day in the year. It opened the door to possibilities in other departments in the Lilly Laboratories. The drying of pills and tablets sometimes offered a problem. Case hardening of eoatings was sometimes caused by drying in air of too low a moisture content. The outside appeared dry and hard. In six months or more, moisture from the inside came through and sticky pills or tablets resulted. Air-conditioning solved this problem. Drying was retarded so that the center was dried first and no moisture was sealed inside. Next, conditioned air was used in the coating of pills and tablets. It did away with guess work and rule-of-thumb standards. The manufacture of effervescent tablets was revolutionized with the advent of conditioned air. The air in the laboratory where such tablets are made should not exceed 15 per cent relative humidity at 90 degrees F. This is the moisture content found on a dry, cold winter day.

In the production and processing of gland products conditioned air adds much to Lilly quality. Glands are for the most part expensive and subject to eontamination. Deterioration is rapid. Therapeutic values are destroyed in some instances if processing takes place at temperatures above 77 degrees F. Air-conditioning removed this hazard and losses incident thereto.

Quarters for guinea pigs, white mice, rabbits, and chickens used in testing Lilly Products and in research work are provided with washed conditioned air.

The story of progress in manufacturing and in distribution is the story of alert management, of constant study, of initiative. It does not mean necessarily cheapening production, saving money, or adding to profit. Primarily it contemplates making a better product, a more effective product, or one that renders a better service to the public .-Adv.

NEW YORK, N. Y.

December 1, 1933

PREVENTING LOSS OF WEIGHT IN THE NEWBORN

By I. NEWTON KUGELMASS, M.D., RUTH E. L. BERGGREN, M.A., and MILDRED CUMMINGS, M.A., NEW YORK, N. Y.

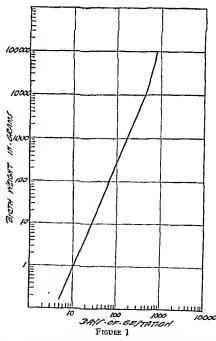

From the Department of Pediatrics, The Fifth Avenue Hospital, New York.
Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, on April 5,1933.

OSS of weight in the newborn is sanctioned universally. It is a period of semi-starvation during the first days of life that is too stupefying to be ignored, too debilitating to be physiological, too prolonged to be a sacred law of nature. A century ago Claussius was the first to record the characteristic loss in weight of the newborn. And such is still being recorded apparently without question. Civilization may have perfected the newborn physique but it has simultaneously impaired the maternal milk secretion; it may have improved the methods of delivery but it has not been contributory in combating the new-born's birth shock. The present postnatal procedure of awaiting an ample food supply from the mother is no longer productive of the nutritional adequacy that maintained in primitive times. The modern consequence is an initial period of semi-starvation, a condition non-existent amongst animals and Bushman progeny. Several questions arise in a careful study of this problem. Is the loss of weight in the nowborn necessary? Is it detrimental? What is its cause? How can it be prevented? Is its prevention advantageous?

IS THE LOSS OF WEIGHT IN THE NEW-BORN NECESSARY?

The newborn is markedly underdeveloped for the duration of human gestation. Birth involves an abrupt change in the newborn reflectanism. It is unprepared for its individuallzed existence in comparison with other mammals, occupying a place somewhere between the domestic mammal and the wild marsupial whose young remain dependent upon the mother. Man appears to be the striking exception in his slow rate of intrauterine development attaining a birth weight of about a quarter of that developed by other animals. Although the relation between birth weight and gestation time is clastic yet it appears on an analysis of animal species that the larger the animal the longer is its embryonic life. If the birth weight is plotted against the gestation

time on double-log paper a straight line relationship is found except for a slight deviation in the case of the heaviest animals. (Fig. 1.) There is some law operative which insures that these limitations necessarily follow. The only reason for using double-log paper is for the convenience of getting the data on the same graph. The time required for the differentiation of man in utero is

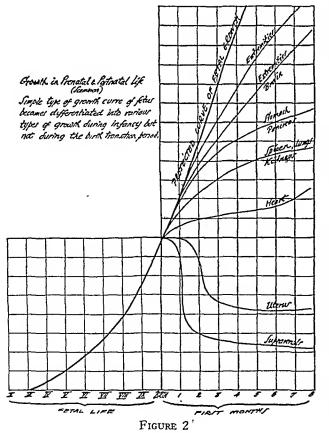

out of all proportion to all animal species. Yet the product is about a fourth of the expected birth weight because of adjustment to the human fe-

N. Y. State J. M December 1, 1933

male. But this high degree of under-development makes the newborn supervision all the more urgent to meet potential pathology with delicate desideratum.

The neonatal growth gradient continues unaltered during the post-natal period. The loss in weight during the first week of life does not reflect any deep-seated change in the growth trend of the neonatal period. The newborn physique is so labile a structure that it reacts manifestly to minor exogenous and endogenous factors that begin to play upon it after birth. But there appears no fundamental change in the growth trend which proceeded undisturbed in utero. This fact we have felt necessary to attain in order not to attempt to alter what was once considered a transitional depression in the growth process. Scammon demonstrated the various types of growth that occur in the body as a whole in comparison with the changes in size of its tissues and organs in fetal and post-natal life. If they be compared by bringing them together on an equivalent scale it becomes evident that the characteristic form of growth of the fetal period continues for several months after birth. This transition is illustrated schematically in Figure 2.

Postnatal loss of weight does not maintain in animals. The birth process appears to be unrelated to any change in the growth cycle postnatally. Such has been the observation of Scam-

mon, Jackson and others for man and of Donaldson, Lowrey, Schmalhausen and others for animals. An inquiry into weight change in animals after birth or hatching shows that no losses result anywhere comparable to those observed in man. Animal species of all sizes, of varied gestation periods, of all scales in evolution, receiving no scientific supervision after birth or hatching appear to thrive either immediately or at the utmost after the second day of extrauterine life. These are the results accumulated from data obtained from animal husbandmen of experimental stations and from curators of zoological parks in this country and abroad.

This survey of uninterrupted growth after birth of animal species is a revelation of the unique place man holds in his adjustment to environmental forces from the very moment of The transient loss in animals is truly physiological in that it consists of some skin, hair, amniotic fluid, meconium and urine. The change represent the irreducible minimum of loss in weight which lasts from an hour to a day since maternal food is already available and adequate for the young. Animals seek the breast immediately after birth and suck continuously unless interrupted by sleep. Even the Bushman mother, free from the stress and strain of modern life is able to nurse her offspring in sufficiency following birth thus minimizing civilization's lag in growth after human birth. (Table I.)

WHAT IS THE CAUSE OF LOSS OF WEIGHT IN THE NEWBORN?

Universality of loss of weight in the newborn without exception has glorified the phenomenon into a so-called physiologic law. A century of literature acknowledges the existence of varied attempt at physiologic correlation. Attempts at interpretation of the newborn's loss in weight have led early investigators far afield.

The newborn excretion is neither massive nor unusual for the sum total of loss due to swallowed amniotic fluid, vernix caseosa, meconium and urine is indeed negligible in comparison with the actual loss of weight during the first days of life. Cammerer demonstrated metabolically that the loss in weight is nothing more unusual than the difference between intake and output. greater portion of the output is independent of alimentary elimination. It consists of fluid loss from the skin and lungs as insensible perspiration not due to an excessive metabolic rate, but rather to an inadequate total fluid intake to compensate for the newborn's daily requirement. Actually, therefore, the loss in weight is due to some starvation which is never physiological. (Table 11.)

HOW CAN THE LOSS OF WEIGHT BE PREVENTED

The effectiveness of therapeutic procedure parallels its degree of dependence upon physio-

logic changes which are to be corrected. Many attempts have been made to decrease the loss of weight in the newborns but without consistent results because the methods devised were apparently unrelated to the fundamental cause of the sudden drop in body weight.

We have initiated our present study as a result of favorable experiences in the nutritional care of prematures. During the first few days of life we were able to correct the striking physiologic deviations from the norm by the oral administration of 5 per cent dextrose solution reinforced with 5 per cent glycocoll offered every two hours immediately after birth. The dextrose consistently alleviated the low blood sugar observed in these premature infants and the glycocoll appeared to raise the internal body heat to a normal level thus overcoming the low birth temperatures. The continuous administration of the solution the first two days after birth between feedings prevented

in a large measure the initial loss in weight which the prematures could well nigh not afford. This observation in connection with premature, debilitated and small infants led us to a more careful study for the development of a solution which would be preventive of the initial loss in weight in all newborns. feeding regime is well tolerated. The actual colostrum intake is small even if valuable and the ingestion of feeding formulae minimal under the most favorable conditions. The amount of food consumed in terms of percentage of body weight is less than one per cent on the first day, gradually increasing to over 10 per cent of the body

The Solution to Combat Birth Shock. The newborn's nutritional requirement can only be fulfilled once he has been alleviated of the symptoms eonsequent upon the physiological trauma of birth. We have observed that nutritional therapy is specifically indicated the first two or three days of life before the required normal

weight after the fourth day. This limited intake is a consequence of birth shoek. We have, therefore, found it advisable to prevent initial loss in weight not by forcing feeding mixtures from the day of birth, but rather by the administration of a solution suitable to the physiologic needs postnatally. After a series of attempts to determine

the relative effectiveness of various measures we have found that the solution

60% gelatin (pH 62) 30% dextrose

05% sodium eliloride

the most desirable for reducing the initial loss in weight of the newborn to the irreducible numinum. It so happens that our favorable clinical observations with this solution have brought out its identity with the gross content of colostrum. This solution was administered to consecutive staff cases immediately after birth and every two hours thereafter for the first three days when the valuable breast milk was supplemented by

life The high degree of bound water content in the newborn is indicative of its indispensability in the body's immitable structure. This presup poses no available water reserve for ready mobilization comparable to fit or carbohydrate.

Determination of the amount of water eliminated from the lungs and skin of newborns reveiled it to be about three times as great per kilo of body weight as that of an adult. In fact the adult retains about 35 grams of water per kilo body weight while the newborn binds about 150 grams of water per kilo body weight or over four times the adult requirement. These considerations of the water metabolism emphasizes the direction of

feeding formula according to the needs of the individual infant (Table III)

The newborn's requirement of the constituents of this solution may be envisaged from the following considerations Continued water administration is indispensable from birth on Stander and Tyler found the fetal water content of the blood was less than that of the mother's We have observed by determination of the refrac tive index, viscosity and blood volume that the blood is concentrated at birth as a consequence of shock and of subsequent water deprivation Normally, the water content of the newborn is about 85 per cent gradually diminishing with age This high degree of tissue hydration at birth is indicative of the correspondingly high degree of immaturity of the hody and necessarily bespeaks the tremendous water requirement at this stage of

dirtely after birth Inadequate fluid intake in the newborn is conducive to the development of a variety of symptoms, initially alimentary in na ture, long before frank deliydration becomes ap parent to the clinician But mere water intake lins shown no consistent maintenance of the required tissue hydration in the newborn marked lability in water metabolism is apparent from hourly determinations of the refractive index of the blood in comparison with that of older We have therefore not only offered water but other dissolved constituents as well to favor its retention. This instability in water metabolism has been interpreted on the basis of immiturity of the central water-regulating mechanism but we have found no evidence for such assumption Addition of nutrious for stabil

intake in newborns has been adequately met by máximal amounts of gelatin and minimal amounts of: sodium chloride. Gelatin has several physiologic advantages for the newborn—markedly hydrating, well tolerated and easily assimilable. Sodium chloride, a neutral salt prolongs the retention of ingested water by virtue of the dual properties of the salt—the hydration of the sodium ion and the neutral salt effect. Studies of the blood composition of newborns have shown that the total protein content is at low normal levels in comparison with older children, a further indication for the addition of gelatin. Similarly the sodium chloride content of the blood of newborns has been observed to be at low normal level gradually rising with regain of the birth weight. Hence the justification for addition of minimal amounts of sodium chloride to raise the low plasma sodium chloride concentration. This restores to blood and tissues their normal degree of hydration in view of the absolute relation of this salt to the water content of the body. But the addition of gelatine has another advantage. By virtue of its specific dynamic action it elevated the body temperature, subnormal And its metabolic products likewise contribute toward the elevation of the blood pressure, lowered as a consequence of birth shock.

Determination of the blood sugar concentration at birth reveals consistently low normal. Therefore dextrose has been added to the solution offered the newborns not only to maintain a normal blood sugar level but as well to offer a readily assimilable carbohydrate adequate at least for the basal metabolic needs of the body during the first days of life. The entire solution is isotonic because half of the molecular concentration consists of three per cent dextrose and the other half of a 0.5 per cent sodium chloride. The solution is further made colloidally osmolar by the addition of six per cent gelatin which parallels the concentration of the blood. The consistency of the solution warmed before feeding is such as to favor retention thus overcoming regurgitation so prevalent in young infants.

The tryptic rather than peptic digestion of gelatin favors a slowness of molecular absorption from the solution, advantageous in the initial alimentary adjustment of the newborn. Incidentally the gross concentration of the solution parallels that of colostrum although our purpose in its administration is of course not at all exactly that which nature transfers to the newborn colostrum. The great emphasis that has been placed upon the physical and chemical properties of breast milk in so far as its universal tolerance in infants is concerned has led to its apparent simulation in artificial feeding mixtures. And so it is in that spirit of simulation of gross properties rather than in duplication of the minutae of colostrum that we compare the solution herein devised. We have attempted to modify the solution further for its acid-base content because of the low pHs observed during the first day of life and the reciprocal CO₂ content that parallels the so-called "acidosis of newborns." The variability of the acidbase equilibrium in the newborn and the refinements we found necessary were out of all proportion to the disturbances produced by the attempted administration of such a modified solution. We have, therefore, been content with a solution which will maintain the required level of tissue hydration and be well tolerated, non-irritating and non-expensive.

Preparation of the Hydrating Solution. To a cup of cold sterile water add about 6 level table-spoons of gelatin (pH 6.2), about 3 level table-spoons of dextrose and about a level teaspoon of table salt. The gelatin should be free from flavoring, coloring or sweetening if it is to be well borne as the first nutrient of the newborn. Allow to soak for 10 minutes. The remaining 3 cups of water required to make a quart of the solution are brought to the boiling point and added slowly to the mixture. The solution is stirred continuously until all is dissolved. This nutrient solution for the newborn consists of 6 per cent gelatin, 3 per cent dextrose and 0.5 per cent sodium chloride, having a caloric value of 12 calories to the ounce.

Clinical Course of Treated Newborns. Solutions of varying composition were tested clinically for relative effectiveness in preventing loss of weight in the newborn. The soluble nutrients were selected as previously discussed on the basis of the therapeutic needs of the newborn after experiencing physiologic trauma incident to birth. Our studies of nutrition of the newborn indicated an initial requirement in a hydrating solution of a coloric value sufficient to maintain basal needs the first three days of life. Such a solution consisting of well tolerated substance-gelatin, sugar and salt-brought more rapid recovery from the effects of the birth shock than did the immediate feeding of milk mixtures. In fact, the final, most effective solution offered during the first three days of life actually prepared the newborns for more efficient nursing and utilization of feedings. The solution was given every two hours throughout the 24 hour cycle. The results are expressed in Table III.

The final hydrating solution found effective clinically consisted of 6 per cent gelatine, 3 per cent dextrose, and 0.5 per cent sodium chloride. When offered to twelve infants with controls at two hour intervals during the day the percentage loss in body weight was no more than 3.4. But when the same solution was offered throughout the 24 hour cycle at two hour intervals both between and immediately after nursing the percentage loss in body weight was the irreducible minimum—1.7 per cent. The caloric intake exceeded the basal requirement in most newborns and thus tided the baby over the first days of reaction

from the birth process. All of the infants began to gain weight on the fifth day of life at a rate which far exceeded that of the controls.

Complemental feeding in 300 control infants merely reduced the initial loss in weight from the usual 10 per cent anywhere from 6 to 9 per cent. The newborns were put to the breast 6 hours after birth and then continued on four-hour mirsing periods with complemental feeding wherever indicated. The actual amounts offered to each baby in varying types of milk mixtures depended on the adequacy of the breast supply. The feedings were offered only after the breast supply was exhausted and continued until the total ingestion of human milk fulfilled optimal requirements in each baby. In common with other observers we have adjusted the complemental feedings without endangering the baby's natural source of nutrition.

The old dictum of Czerny's of not offering newborns any feeding until the breast milk has become available, no longer holds. The basis of that practice was to ohviate the development of unnatural and harmful fecal flora, a condition that has never been confirmed bacteriologically. The modern prolonged interval for the development of an adequate supply of breast milk no longer warrants the practice of semi-starvation. As a result the enfeebled infants lack the energy to nurse, particularly from engorged breasts. Incomplete emptying of the breast is in itself the most effective stimulus for milk secretion. The consequence is a vicious cycle with an unnecessarily prolonged adjustment to the optimal nutritional requirement.

Early complemental feeding invigorates the newborn to the extent of obtaining more breast milk, hence it is mutually beneficial in accentuating the most effective stimulus to increased breast flow. Careful regulation of complemental feeding never minimizes effective nursing. But complemental feeding in the 300 newborns observed has not resulted in eliminating the initial loss in weight. Administration of the hydrating solution the first three days between nursing and then complemental feeding with nursing evidently propared the newborn for rapid adjustment to the required breast and artificial feeding.

The control series revealed a greater loss for larger newborns. Even on complemental feeding 9 pound infants lost on the average about 9 per cent of their birth weight while smaller infants lost less but never below 6 per cent of their birth weight. (Table IV.) The striking advantage of the administration of the hydrating solution was to equalize this variation in postnatal loss of weight to the extent that the average was less than 2 per cent.

The clinical superiority of the newborns who received the hydrating solution led us to favor the latter procedure on the basis of its maximum

Initial Loss of Weight in 300 Newborn Controls (Breast and Complemental Feeding)

effectiveness in behalf of the newborn. (Figure 3.) The cousiderable fluid intake showed by the newborns receiving the hydrating solution is, of course, paralleled by an increased caloric intake in comparison with the controls during the first critical three days of life. It is to be reiterafed

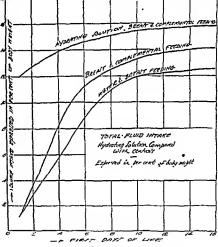

FIGURE 3

that the primary purpose was not caloric adequacy but rather fluid adequacy although it was intended to offer the newborn at least the caloric requirement essential for basal activity, that is, at least 150 calories for the first 24 hours. (Table V.)

Newborns adequately hydrated rapidly lose the so-called physiological apathy, somnolence and stupor. Newborns maintained on water the first three days in addition to the inadequate supply of breast milk not infrequently showed acetonuria. It has already been universally demonstrated that the compensated acidosis of the new-

TABLE V

born is an entity which undoubtedly contributes to the familiar newborn apathy. The administration of the hydrating solution effectively cleared this needlessly accepted symptomotology.

Adequate hydration of the newborn freed him from the familiar starvation stools. On the "solution" the meconium stools were larger and more rapidly eliminated during the first three days of life than in the control series from which meconium continued up to the fifth day. Pediatricians have often associated prolonged meconium stool elimination with periodicity of alimentary dis-turbances. The toxic symptoms which have been found to supervene have made it a practice amongst many to resort to castor oil. We have observed that such a procedure aggravated the dehydration even though it cleared the transient The newborns under observation disturbances. showed no such upsets and required no special alimentary therapy. Their temperatures were better stabilized in comparison with controls. In fact, the fluctuant temperature variation in the newborn has lead many to advance its cause on the basis of an immature temperature regulating mechanism. We have observed the least number of febrile infants throughout the year of this study and none, of course, with dehydration

Conclusions

1. Loss of weight in the newborn is sanctioned universally without physiologic foundation.

Discussion

Dr. E. A. Ricsenfeld, New York. At the Harlem Branch of Bellevue and Allied Hospitals in this city, on the service of Dr. Geo. Brodhead, observations were made for a period of one year on the temperature of the delivery room at the time of delivery. It was found to average 70 degrees F.

2. The newborn is markedly underdeveloped for the duration of human gestation and so requires continuous supervision for the prevention of potential pathology.

3. The neonatal growth gradient continues unaltered during the postnatal period according to analysis of the transitional growth trends of the body as a whole as well as of its tissues and organs; therefore the initial loss in weight is nec-

essarily extrinsic.

4. Postnatal loss of weight does not maintain in animals of all sizes, of varying gestation periods and of all scales in evolution according to a survey of observations of veterinarians, animal husbandmen and curators in experimental and zoological parks in this country and abroad.

- 5. The initial loss of weight in the newborn is the result of dehydration and semi-starvation, conditions unfavorable for nutritional, physical and environmental adjustments besetting the newborn.
- 6. Past therapeutic procedures for decreasing the loss of weight in the newborn have not been altogether effective because they were not based on the physiological needs of the newborn disturbed by birth shock.
- 7. The initial loss in weight in the newborn can be prevented by the administration of a solution consisting of 6 per cent gelatin (pH 6.2), 3 per cent dextrose and 0.5 per cent sodium chloride at two hour intervals throughout the 24 hour cycle immediately after birth. The gelatin hydrates blood and tissues; it raises body heat by virtue of its specific dynamic action; and reduces the clotting time. Dextrose brings the newborn hypoglycemia to normal. Sodium chloride raises the initial low blood chloride and favors hydration.
- 8. The average loss of weight in newborns receiving the hydrating solution was 1.7 per cent, the irreducible minimum in comparison with the average loss of 7 per cent.
- 9. The characteristic clinical picture of the newborn is a result of birth shock, more effectively combated by a hydrating solution than by milk mixtures the first two or three days of life.
- 10. Preventing the loss of weight in the newborn produces rapid disappearance of the so-called physiological apathy, somnolence and stupor in the newborn secondary to birth shock and the compensated acidosis universally present.

Accurate stop watch observations were made without the knowledge of the accoucheur, and it was found that an interval of about ten minutes elapsed from the moment of birth until the infant was eventually wrapped in blankets.

The body of the newborn infant is moist, frequently actually wet. It is covered with vernix casiosa, amniotic fluid and blood.

The child at birth is thus subjected to a temperature change of approximately 30 degrees, the difference between the temperature of the interus of the mother, 98.6 and 70 degrees the temperature of the atmosphere into which it is born. This chilling continues for about ten minutes with a moist or wet body surface. Budin was the first to call attention to the harmful effects of such chilling, particularly as it affected the premature child.

We felt that in this prolonged chilling, there might be a factor which influenced the amount of

weight loss sustained.

To control the chilling electric heating lamps were placed at a distance of 20 inches from the vulva of the mother. The infant would then be born into an atmosphere of 99 degrees, that of the uterus of the mother. The weight was determined at birth and at the end of 24 hours. As other important factors beyond our control

modify the weight thereafter, the loss of weight during the first 24 hours alone was considered.

It was found that infants protected by heat sustained a lessened weight loss when compared to a group of infants born at the same time at the Woman's Hospital in the city on the service of Dr. Studdiford and a control group of Harlem Hospital.

In all children protected by heat there was an average actual loss of 3.4 ounces or 3.2 per cent as compared to the loss sustained by infants born under the usual circumstances of an average actual weight loss of 4.6 ounces and a percentage loss

of 4.6.

In those children under 5 pounds however, it was found that the heat protected children suffered a loss of 2 ounces averagely or a 2.9 per cent loss compared to the control group of infants under 5 lbs. who sustained an average actual loss of 5.1 ounces or 8 per cent.

THE TREATMENT OF COMMON FORMS OF DROPSY*

By NELLIS B. FOSTER, M.D., NEW YORK, N. Y.

T is recounted that in his experiments with digitalis Withering was disappointed that this drug produced no alleviation of the dropsy of ovarian cyst, or of hydrocephalus. Looking back from a future century some of our efforts today may seem quite as lacking in understanding of the complex problem of edema. For today, despite notable increases in our knowledge of some of the factors involved, it would be a simple problem indeed when a clinician might feel assurance that he could predict the effect of a chosen measure for relief in a specific instance. And while our reasoning today rests upon a broader and more tangible body of facts that it did, even a decade or two ago, we are often confused by the complexity of physiological relations and must at times resort to an unreasoned trial-anderror method of therapy.

Until the nineteenth century dropsy was considered a clinical entity; there are exigencies when because of its severity and immediate danger we have to act as though it were so regarded even today. But generally it

is a symptom.

In a way which is doubtless crude, the causes for edema may be grouped and their general nature indicated. Excluding for lack of time those edemas which seem to be due in large part to injuries in the lymphatic system, (e.g., elephantiasis), edemas are referable either to changes in the capillary endothelium or to changes in the body fluids. The capil-

laries may sustain organic lesions as in acute inflammations, or poisoning, or functional changes due to deficient oxygen, or to nerve influences. The body fluids may be altered by disease in respect to their content of electrolites or colloids.

Swelling is one of the clinical signs of in-flammation. The principle concerned in its production is an increased permeability of the capillaries; in familiar terminology there is exudation. The tissue fluids in these edemas contain more serum proteins than is the ease with what we call transudates. There has been but slight dissent to the idea that edemas adjacent to areas of infection are directly referable to capillary lesions, and the principle of mechanical drainage has been accepted as the proper therapeutic principle when the fluid collection delays repair, whether the tissues implicated be fascia, pleura, or peritoneum. But when the idea of capillary injury is extended to explain the quickly developing edema associated with acute Bright's disease, we feel possibly the need of specific new evidence. This evidence in the main consists of the accumulated facts indicating that the disease, acute Bright's disease or glomerular nephritis, is not restricted to the kidney, but involves the vascular system generally to such an extent that the name capillaritis has been suggested.1, 2, 8 Also the edema fluids in this disease by their richness in protein suggest that they belong to the old class of exudates. A critical study of all the available facts indicates that while the capillaries are affected in

^{*}Read at the Annual Meeting of the Medical Society of the State of New York, at New York, N. Y., April 4, 1933,

acute Bright's disease there may well be some other unknown principle operative. At present it is not entirely clear whether the oliguria of nephritis is a result of the lesion in the glomerulus, per se, or whether it is due to the withdrawal of water from the blood as edema fluid. In either case the essential disturbance of water balance is not accessible to any known therapeutic control and as a matter of experience the edema of acute Bright's disease is but seldom a dominant symptom and hardly ever requires especial attention.

In contrast to edemas believed to be caused by lesions of the capillaries are those due to some sort of functional change in the capillary wall; a change which permits the passage of water and electrolites from the blood into the tissues but does not allow an escape of considerable amounts of plasma proteins. This condition conforms to the older definition of a transudate and this type of edema occurs commonly along with disorders of the circulation, whether due primarily to heart disease, or to such slowing of normal blood flow as may result from occlusion of blood vessels. In this sense the edema of heart disease and the ascites of cirrhosis of the liver are alike in their mode of production. Until quite recently it was believed that this transudation of water through the capillary walls was dependent chiefly on an increase of pressure within the This hypothesis seemed to fit the capillaries. conditions of cardiac, edema especially; but Landis has thrown some doubts upon the pure filtration theory of Krogh in showing that the capillary endothelium is peculiarly sensitive to deprivation of oxygen and even slight anoxemia induces a prompt increase of capillary permeability. Because theories applicable to clinical medicine are based largely on indirect evidence and analogy it seems to me probable that both factors, anoxemia and hydrostatic pressure, play a part in "stasis" edema, and even the integrity of the capillary endothelium may well be questioned. The fluid in this type of edema is not free of serum protein, though commonly it is less than with the inflammatory type, every clinician has been impressed by the severity of albuminuria which may accompany cardiac insufficiency in children and the promptness of its subsidence when heart function improves. Both of these facts suggest a degree of permeability of capillaries approaching that found in inflammation. Then there is the influence of electrolites which will be discussed later.

Even this brief summary of some of the known factors in the causation of cardiac edema is sufficient to indicate the complexity of the problem. And stasis edema would seem a relatively simple type. So it is to be ex-

pected that while therapeutic effort may be, in a general way, intelligent and rational, there remain always problems which are more or less solved by trial-and-error and the reason for success is as obscure as for failure. While rest or rest and digitalis is adequate in some cases, in others the amount of liquid in the pleural cavity requires prompt mechanical relief by aspiration not only to relieve distress but to remove a mechanical burden from the heart. Primarily, treatment is directed to aid the function of a diseased heart and it is sometimes overlooked that edema is in itself a burden to a laboring heart; and palpable edema is not a valid guide in estimating tissue edema since some six to eight pounds of fluid may accumulate in the tissues before palpable edema is evident. Possibly this may be the reason why a diuretic produces such prompt improvement in some cases of cardiac incompetence when rest and digitalis alone have not availed. It is not then in neglect of the primary disease if particular attention be given to stubborn edema in cases of congestive heart failure. Quite the contrary.

In spite of the bewildering array of drugs which are vaunted as especially adapted to meet the need in cardiac dropsy, experience as well as tradition suggests that the first choice be a mercurial. Paracelsus used mercury for dropsy; in various forms it was held in high regard by Morgagni, Stokes and Graves, and Guy's pill under various names held its place until recently overshadowed by organic mercurials such as mersalyl (Salyrgan). Nor is the effective use of these organic mercurials limited to cardiac disease. They are useful even in nephrotic edemas to which I shall revert later on.

It is, I think, a just criticism of our present theories of the causes of edema that none of the hypotheses helps very much in understanding how diuretic drugs free the tissues of excesses of water. There is some evidence that mercurial salts decrease the resorption of water by the renal tubules, an idea consonant with present theories of renal function, and with the fact that excretion of water and sodium chlorid are particularly affected in diuresis induced by mercury. But we have only a superficial understanding of the mode of diuresis caused by caffein, for example, or by potassium salts, or by the salts which induce an acid shift in body fluids, e.g., ammonium nitrate.

Before leaving this topic of mercurial diuretics and mersalyl in particular, I wish to call attention to an erroneous conception concerning their use. The error is based on the fear of mercury poisoning if a mercury salt be repeatedly and at relatively short intervals injected into the blood stream Lyperience indicates that the hazard must be trivial. The intravenous use of one or two cc of mersalyl every four or five days for as long as three years leads to no detectable damage. In a high percentage of cases a diuresis of 3000—4500 cc may be expected. The sole contra indication is hematuria.

While conceptions of the relation of sodium chlorid to edema formation have changed, this change in theory has not affected the therapeutic indication for salt restriction in edemas and dropsies generally Widal's theory that chlorids can not be excreted by a diseased kidney, and that this failure causes an accumulation in the tissues with the holding back of water to maintain isotonicity, has to be con siderably changed to accord with present knowledge There can be no failure of chlorid excretion in view of the diuretic effect of acid salts such as calcium chlorid. It appears to be a matter more concerned with sodium since sodium salts appear to increase edema in contrast to potassium salts which often cause edema to decrease. And it is to be noted that the kidney is no longer held primarily at fault Whatever retention we may speak of, whether of salt, sodium, or water, is in the tissues soon as the tissues release excess water and salt to the blood, excretion promptly occurs, and while sodium salts are not primarily responsible for edematous states they are of great secondary importance since they determine so largely by their presence the degree of water retention in tissues predisposed to edema by other conditions Despite changes in theory then it is generally believed that a restriction of salt is a useful method in the control of edema whether of cardiac or renal

The Karell duet made popular by the approval of Yon Noorden is in fact a restriction of salt and water. The basic idea in this "cure" was advocated by Serre and it is referred to by Cruchet. La cur doignon dans oedema et le regime sec. (Jour de Med de Bordaux, 12 fevrier, 104 1911). The regimen was abstention from fluids and as the only food, three milk soups per day, each meal ending with a piece of bread and a raw onton

But we cannot dismiss the subject of the relation of sodium chlorid to edema with a merc mention of salt restriction as a therapeutic measure. That potassium salts act as diuretics has long been known, saltpeter is one of the oldest. Their use displaced in changing modes seems revived and put on a more systematic basis. Baker has recently shown that a diet may be arranged to furnish an excess of potassium over sodium and that such a potassium rich diet is remarkably effective in some cases of edema due to cardio-vascular disease. It is interesting, in passing, to note that while sodium is the predominating ele

meut in intercellular fluids, blood and lymph, potassium predominates within the cell Here is a subtle relation not clearly understood as yet and of considerable significance, I suspect, in the problem of edema. When there is an indication for the restriction of sodium chlorid in the food, it is worth trial to substitute potassium chlorid for table salt,-about five grams daily is adequate Potassium in large amounts is a cellular poison and the sort of treatment described cannot be continued in-The peculiar virtue claimed for the definitely Osman method of treating edema is possibly duc to the potassium in his alkaline mixture Osman believes that the liberal use of alkalies is the best way to combat the edema of Bright's disease An alkaline urine is the guide attain this a mixture of equal amounts of sodium citrate and bicarbonate, potassium citrate and bicarbonate are given in amounts up to a thousand grains daily In sharp contrast with Osman's ideas are the prevailing practices in this country today. We depend more upon acid salts and strive for a state tending towards acidosis This is the effect produced by such salts as calcium chlorid and ammonium nitrate

Thus far we have mentioned those types of edema which seem to depend in large measure on permeability of the capillary vascular system. In contrast to this group is edema induced by changes in the colloids of the blood. This change in blood colloids is responsible for the edema of maintion, of some anemias, of the so called nephrotic type of Bright's disease, and not seldom it is a factor in cardiac edemas as well

In the capillaries there are two opposing forces, hydrostatic pressure which tends to drive fluid through the capillary wall into the intercellular spaces, and the proteins of the blood which, as colloids, tend to draw fluid from the tissues into the blood. According to the Starling theory, the interplay of these two forces determines fluid exchange between the blood and tissues.

A lowering of the serum proteins from any cause whatsoever would tend to disturb the physico chemical balance and, unless in some way compensated, would lead to edema Marked decreases in serum albumen concentration have been found in nephrosis and in manition, and this lowered serum albumen is generally believed to be one of the chief agents in the production of the edema in those states This type of edema has been reproduced, cyperimentally in animals by plasmaphoresis, and by low protein dietss, so that our understanding of the physico chemical processes involved is somewhat better than with edemas of a different character While it would be unwarranted to leave the impression that colloid osmotic pressure is the sole factor involved

in nephrotic edemas, that this is an important factor seems to be demonstrated by the effect of intravenous injections of acacia on diuresis Hartmann¹⁰ treated a series of and edema. cases of nephrotic edema by repeated injections of acacia into the blood stream. The amounts of acacia used varied but were sufficient to raise the colloidal pressure of the blood plasma above the critical edema level. The results on the whole are remarkable, not only on account of the therapeutic value of the method, but also because of the support which this method gives to the basic theory. Normal serum has a colloidal osmotic pressure of 30-40 cm. of water. When the albumen content of serum is reduced, (as in nephrosis and inanition especially), the osmotic pres-In hydropigenous nephritis sure also falls. the osmotic pressure is often below 20 and may be down to 10 cm. of water: edema is then a probable consequence. A high protein diet designed to replenish serum protein, as first advocated by Epstein,11 is now accepted as rational and scientific in the treatment of nephrosis. But the earlier conception, that any form of Bright's disease was an indication for restriction of protein in the food, is hard to displace. Also it is not generally appreciated that depletion of serum protein may occur in any form of chronic Bright's disease, and in chronic cardio-vascular disease as well, and edema develop as a consequence. In fact, there has been something of a revolution in our ideas concerning the dangers of protein foods in renal disease. It might best express not only the present knowledge, but also the present mood, to assert that the dangers of protein restriction are feared more than the dangers from overburdened kidneys. In brief, the most effective method of treating hydropigenous Bright's disease and cardio-vascular edemas includes a liberal protein ration. Restriction of salt and an adequate protein ration are basic indications in renal dropsies and they are useful measures in some cases of edema due to cardiac disease as well.

The reaction against the low protein diets of a decade ago has been complete. Even in hemorrhagic Bright's disease there is evidence not only that the patient improves on diets containing normal protein rations but also that kidney function is better. McCann, J. Clin. Investg. 11:973, 1932.) (Kautmann &

My discussion has been limited to the immediate physiological processes concerned in edema formation. The ultimate control of the water exchange in the body, whether dependent on central nervous system or endocrines. is not sufficiently understood to permit the practical application of theories to treatment. Eppinger believes that thyroid function influences the permeability of membranes and there are observations on record suggesting that occasionally parathyroid extract as well as thyroid acts as a diuretic. The relation of the hypophysis to diabetes insipidus indicates a remote control of water metabolism, the immediate mechanism being still largely unknown. There are in this realm some facts. many assumptions and hypotheses, but hardly anything we can turn to practical advantage at present.

Two methods of relieving edema, (popular until recently and still used somewhat), have fallen into disrepute and I mention them only to condemn them; -sweating and purging. While it is true that water may be removed from the body in these ways, the loss is relatively inconsiderable; while the exhaustion and weakness prevent any systematic continued use of. these forms of treatment.

THE PRACTICAL APPLICATION OF RADIOSENSITIVITY AND TUMOR GRADING*

By DOUGLAS QUICK, M.B. (Tor.) NEW YORK, N. Y.

TUMOR pathologists have for many years recognized distinct histological variations between tumors of the same group-

* Read at the Annual Meeting of the Medical Society of the State of New York, at New York, N. Y., April 4, 1933.

among others, variations in the degree of cellular differentiation. During the past few years this has been popularized under the cap-tion of "tumor grading." Covering about the same period of time, studies of tumor tissues

relative to their response to irradiation have thrown light on many factors which influence a tworable reaction to the physicial agents

There is a relationship between timor grading and relative radioscusitivity. Unfortunitely, it has been assumed by many that the response to irradiation is in parallel with the histological grade of the tumor. Such is not the ease.

the fully differentiated growth is more te sistant to a given quantity of radiation than is the undifferentiated or anaplastic growth of the same tumor group. In so far, there is a parallel between relative radiosensitivity and tumor grade from I to III or IV, depending on which numerical basis grading is being cinployed There is a distinct variation, however, between different cancer groups Beyond this point there are many factors, both within and without the histologie field, which have a distinct bearing on the relative response of a given tumor to irradiation. The elimician will do well to study those factors of recognized influence and match them with the histology before airiving at an appraisal of the probable degree of response to a given type and inten-sity of irradiation. The astute tumor path ologist will refrain from more than a tentative opinion of radiosensitivity, based on the study of the slide alone Hc will require very conplete clinical data before expressing his final opinion

Grading is a problem of histology alone Classification of relative radiosensitivity is a matching of histological and clinical pictures Grading is influenced by the personal equation of the individual tumor pathologist

Determination of probable response to irradiation is based on a much broader back ground. Once the necessary data are available the appraisal is likely to be more uniform. There is no comparison in radiosensitivity, histologically between the different major groups of tumors. This is a matter determined on the basis of chinical experience only.

There are few cases of cancer m which all three of the recognized therapeutic methods or agents—i e surgery radium and yray—do not play a part to advantage at some stage in the care of the case. It is a matter of deciding the relative position of each in the individual case. The practical value of a radiosensitivity appraisal is its application in the making of this decision. It is here that tumor grade may be taken too literally as a measure of the relative radiosensitivity of the growth.

The fully differentiated, or grade I tumor is usually the more radioresistant. It is in general, slower in rate of growth, and tending toward some degree of localization. Its metastases are later in the course of the disease and

tend to be localized to adjacent lymplinode neas, rather than to widespread dissemination

Anaplastic, or grade IV timors, metastasize early and widely They may extend through the blood stream as well as through the lym Their tumor emboli may pass by regional lymphnode areas and lodge in those of distant parts of the body The rate of growth of metastases may out-do the punnary by many times, so that the latter becomes entirely obscured in the clinical picture. These undifferentiated growths are obviously not adapted to surgical extirpation which even in its most radical form, is a local measure While the tumor is being surgically removed at one point it is appearing at another It is the opinion of some workers that partial removal of a tumor lends growth stimulus to the remaining portion Fortunately, the anaplastic growths are very sensitive in their response to irradiation

If there were but two groups with which to deal, the problem would be simple. The fully differentiated eaneer would be handled surgically, the totally undifferentiated by tradiation, and the histological picture, or tumoi grade, would define the two groups. However all tumors are neither fully differentiated nor entirely anaplastic—hence the four grades in the average scheme of tumor grading. Furthermore, factors, other than cellular differentiation have an influence on the relative position of a given tumor in the scale of radio response.

Some tumors have a much more delicite blood-vascular apparatus than others, so that with such, a partially differentiated growth (grade II or III) may respond to irradiation more promptly and more completely than a totally anaplastic tumor of the same group, but lacking in such a highly specialized capillary circulation. The infiltrative character of the cells of a malignant growth, or the lack of reaction on the part of surrounding tissues to this invasive characteristic, may after the response to irradiation, although it does not change the histological grade.

Recurrent growths are for the most part more radioresistant than their primary—even though unchanged in grade. This is reasonably understandable of the original growth was treated by one of the physical agents. It would not be expected theoretically following some form of surgical removal since recurrences following such tend to show histological evidence of a loss of growth restraint—a tendency towards anaplasia. The alteration in the tumor bed of the recurrence suggests at least one factor of influence. The extra scar tissue and grossalteration in blood supply are sufficient to discount what might be termed an otherwise

normal response to irradiation, for that type of tumor tissue. This observation may have a bearing on the much debated question of the relative merits of pre- and post-operative irradiation. Scar tissue and the resultant decrease in blood supply regularly reduces the response to irradiation, whether such process be in the tumor bed or within the tumor bearing area itself. The recurrent growth furnishes an example of the former. Fibrosis and capillary impairment is seen in the cases of luetic glossitis. Cancer in this type of tongue is less radiosensitive, per given histologic grade, than in an otherwise normal tongue.

The anatomical location of a growth has a bearing on radiosensitivity. Again the tongue may be cited as an example. Epidermoid carcinoma, of whatever grade, involving the base of the tongue, will almost invariably respond to a lesser quantity of radiation than a similar growth, of comparable grade, involving that portion of the tongue within the oral cavity proper. The normal histology of the tissue of origin is undoubtedly one of the factors entering into an explanation of this peculiar reac-The base of the tongue is technically more difficult to approach from a surgical standpoint. This alone, however, does not explain the almost total tack of cures, of cancer at the base of the tongue, by surgery. Most cancers in this location show some lack of differentiation. The obvious lesson is that undifferentiated growths are non-surgical.

Those who believe that tumor bed, as well as tumor tissue, enters into the vital favorable reaction to irradiation, may explain some failures to respond on the basis of anatomical location. The osteogenic tumors of bone, with one exception, are highly radioresistant. The tumor bed of the bone tumor has less to offer by way of response to irradiation than probably any other tissue in the body. Some of the resistance and failures in breast cancer may be, at least partially, explained on the same basis. The diffuse infiltration in fat tissue is less responsive to irradiation than in the absence of that fat tissue. The practical point therefore is to lean more heavily on surgery in the . fection of tumor and tumor bed, irradiation is fat cancer breast.

The degree of local advancement of growth discounts its relative radiosensitivity. histology does not change appreciably in a primary uncomplicated growth, as it progresses. Yet, with age of tumor process and gradual increase in size, it responds less to a given quantity or radiation. Usually the ratio between the tumor bed and tumor becomes The blood supply is frequently altered so that peripheral or central necrosis, depending upon whether it be a flat ulcerating growth, or a bulky more or less spherical, non-ulcerating one, occurs.

Secondary involvements at distance—metastases—are usually less radiosensitive than the primary growth. Once the disease has become generalized it is much less responsive. It may even change from a relatively radiosensitive to a frankly radioresistant process. This change is frequently, in far advanced and widely disseminated cancer, out of proportion to the recognized factors of influence. It suggests an underlying constitutional influence, such as possibly a profound disturbance in the secretion of hormones. There can be no doubt but that the age or duration of a growth, whether it be primary, metastatic or recurrent, within tissues, enhances its local stability and its resistance to external influences, irradiation included. Early diagnosis and prompt treatment, whether by surgery or irradiation, has therefore more to commend it than simply the danger of local growth advancement and secondary dissemination.

Whether metastasis has taken place by blood-stream or lymphatics is of importance from the radiosensitivity standpoint. Tumor emboli carried through the lymphatics are usually lodged in a lymphnode where the normal growth-restraining influence of lymphoid tissue makes its impression, even though that reaction is not sufficient to completely restrain Blood-stream tumor emboli are usually caught in fine capillary vessels, principally of the lung, where the implant is well nourished, and where there is little chance of an inhibitory influence of tumor bed. For any given tumor, blood-borne metastases are more radioresistant than are those dissemi-

nated through the lymphatics. Probably no single factor alters the relative radiosensitivity of a tumor more than infec-Infection is invariably present on the surface of an ulcerating growth and it frequently finds its way into the liquefied debris of tumors showing central necrosis from interference with blood-supply. Uncontrolled infection on the surface of ulcerating cancer soon penetrates, and permeates the entire growth. In the presence of acute and uncontrolled inwell nigh useless, even though the histological picture suggests otherwise. If the growth be assumed anaplastic, this might be taken as an extreme example of the divergence between tumor grade and radiosensitivity.

Passing from strictly local factors, there are various constitutional influences having a bearing on the irradiation response of cancer, and altering it from the optimum response to be expected, from the grade of the tumor alone. The age of the patient, and complicating general medical conditions, have an adverse influence. The retarded threshold of tissue metabolism affects tumor tissue as well as

Reparative processes cannot be expected to be as clastic. The normal slowing down of body metabolism with age is intensified in the presence of anaemia. While anaemia is a part of the advanced-enner picture it may be present and quite apart from the neoplastic process Under either eircumstance it reduces the response to irradiation. A tumor judged histologically to be radiosensitive, may in the presence of a profound anaemia, be unresponsive to the point of seeming resistance. Correction of the annemia will go far toward restoring its latent and favorable reaction Transfusion, liver extract, and iron, play a real and necessary part, along with the physical agents, in the treatment of eaneer in the anaemie

The manner in which irradiation is employed has substantial bearing on the ultimate result of treatment, and regardless of the grade or relative radiosensitivity of the tumor fact that a tumor is judged histologically to be anaplastic and radiosensitive, with no ad verse complicating factors does not mean that it will resolve under simple or indifferent irradiation. It would perhaps be better if we thought in terms of radioresistance rather than radiosensitivity Whatever the technical type of irradiation decided upon, external or implantation, the minimum quantity to be employed with safety is usually the maximum of that type, consistent with the safety of the surrounding normal tissues A tumor which will respond completely to a given amount of irradiation over a period of a month will probably not be eradicated if the same quantity of irradiation is spread over a six-months' period No single tumor mass remains even relatively radiosensitive for more than a brief period once radio therapy has been directed to it If the object of treatment be cure, rather than palliation then the radio therapist has but one chance for success. If adequate intensity of irradiation is not employed in the first complete treatment period, the chance of overcoming the handicap, by further indifferent treatment is slight indeed

A study of the relative radiosensitivity of

a given tumor, based on histological, and the associated clinical evidence, will give a fairly shrewd insight into its probable response to irradiation. It will indicate those extremely anaplastic, undifferentiated, growths in which surgery is contra indicated, and which will probably respond to external irradiation alone. It must not be assumed, however that since they are highly radiosensitive, and disappear locally under external irradiation only, that they are therefore readily curable. Their liability to widespread dissemination seriously discounts their local response, from a practical standpoint.

A large group of moderately radiosensitive growths may be completely destroyed locally by intensive external irradiation, in the present stage of development of this type of radiation. The group embraces chiefly, but not entirely nor of necessity grade II and III tumors. They can scarcely be trusted, however, to external treatment. It is safer to follow the external irradiation by implantation of radium or radon. In general surgery, except for exposure to facilitate implantation, is apt to

accomplish little in this group

The fact that a enneer is classified as radioresistant does not mean that it is of necessity incurable or that irradiation is contra-indicated. It does mean that if irradiation is employed it must be of maximum intensity, both external and by implantation. It signifies also the group in which surgery is safer and more apt to be successful than in the moderately or extremely radiosensitive classes. A good local result in a tumor rated as radioresistant carries a far better prognosis, with either surgery or irradiation, than does any in the radiosensitive groups.

If the radiosensitivity data now available are practically applied, we shall no longer sce resistant growths treated by external radiation alone, when other methods might be added Surgical removal of embryonal and anaplastic tumors will cease. Efforts at irradiation, by whatever means, will not be carried on without proper attention to the general medical

and constitutional care of the patient

RAT-BITE FEVER IN CHILDREN

A Clinical Case

By FRANK VAN DER BOGERT, MD, SCHENECTADY, NY

OMPARATIVELY rare at any age else where than in Japan where, according to Jordan¹ three percent of the house rats have shown spirochate rat bite fever his been believed to be less frequently encountered in cluldren than in adults. A greater incidence

in later life would naturally be expected since the consideration of an occupational factor seems justified. Except in those cases where the bite has occured while playing with pets, children are presumably only in danger from aggressive animals impelled by hunger. Rueben and Steffen² in July, 1924 found among 47 cases in which the age was stated, only 11 under 15 years; and Dembos in reporting a case in an infant aged 7 months suggests that since most of the cases described have occured in adults, this should be of especial interest to the pediatrician. Recently, however, a list of cases reported between the years 1839 and 1930, compiled by Bayne Jones, apparently shows that children are not less susceptible to the disease. In a group of 75 instances of the infection, the reports of which were carefully studied to eliminate doubtful cases, the age was given as 15 or under in 35. Inasmuch as in 21 the age was noted as questionable it would appear that the disease is no rarer in children than in adults.

In American pediatric literature of the last twelve years, I have found but six cases under 2 years of age, with scattered cases in infants

appearing elsewhere from time to time.

The disease is usually occasioned by the bite of a rat either through deliberate attack or while playing with a pet animal; there are, however, several instances on record following bites of other animals: cat, wild mouse, weasel, the dog, and even the pig.4 A few cases have apparently been caused by the bite of the white rat.

The accepted criteria for diagnosis include a definite history of the bite, local inflamation at the site of injury following a variable incubation period, a bluish red macular eruption and a remittent type of fever. The original wound heals and after a period which may be extended to several weeks (10 to 28 days) becomes inflamed and edematous; lymphangitis and adenitis may follow.

Elevation of temperature is accompanied by the characteristic rash, described as consisting of bluish red, edematous, marginated macules which may measure as many as 10 c.m. in diameter, and may be preceded by a chill, apparently not constant. The time of appearance of the rash in relation to the temperature varies. In one reported case2 it did not occur until several days after admission to hospital and in another5 was coincident with the second febrile attack. A few days of fever is followed by fall to normal, not always by crisis in children at least, with another rise after a period of a few days during which the patient is symptom free.

By no means all of the reported cases have been confirmed by finding of the organism which is now pretty generally conceded to be a spirochate. Of the seven infantile cases studied, including my own, in only one was the organism found, diagnosis being based upon the history and accepted syndrome and supported by the therapeutic test of recovery under treatment with arsphenamin.

The prognosis is good, the mortality probably far below the ten percent usually attributed to it. Apparently most of those dying from the infection have been of advanced age and there seems little cause for anxiety as to the outcome in the young and physically fit when the disease is recognized and treated. None of the seven cases referred to were fatal; I have however, found reference to an infant of three months who died from "an attack with unusual complications."6

The disease is said to be preventable by prompt cauterization of the wound by carbolic or nitric acid.7 Fuming nitric acid as applied to dog bites in the prevention of Rabies

is suggested.

Spontaneous recovery may occur. muscular injection of sulpharsphenamin given at the onset of the paroxysms produces most favorable results.

Case Report

On June 3, 1933, at 4 A.M., an infant of 21/2 years awoke with several punetured wounds on his left foot and a good deal of blood on the sheets. A rat had been seen in the bathroom an hour before the injury was diseovered and three rats were caught in the house during the following week.

The patient was brought to the Emergency Department of the Ellis Hospital at 9:30 on the same day, and the wounds were eauterized. Apparent healing followed until about 10 days later when the foot became swollen, looked as if about to break down, and a red streak was noted running up the ankle. There was a story of apparent fever, on and off, from the beginning, which increased when the wound swelled. No history of a chill was obtained.

The child was admitted to the Pediatric Service on June 30, 1933, with rectal temperature of 101.4° and a very definite skin eruption appearing in plaques of a purplish hue, and distributed over lower limbs, trunk and face. The lesions were far more pronounced upon the left leg and the area about the original injuries was purple and inflammatory in appearance. The size of the individual lesions varied from small maeules to some which measured several c.m. in diameter, and, during the period of hospitalization, it was noted that pain and swelling of the injured foot occurred just prior to or simultaneous with rise in temperature. The inguinal glands, though not greatly enlarged, were distinctly pal-pable. There was no evidence of abnormality elsewhere upon physical examination.

Upon admission the temperature curve declined for a few days, rose again on the 4th, reaching 104.4° within 24 hours and declined again slowly to normal on the 7th day with a slight exacerbation on the 9th and 10th. Following seven days of normal temperature a second remission occurred followed by a third on the 32nd day in hospital. During the first remission the color of the rash deepened and there was complaint of soreness all over the body. The third remission was much more prolonged and was accompanied by profuse diarrhea and at this time bacillus dysenteriae was isolated from the stools. Whether the last atack was due to the original infection or to the complicating dysentery is problematie; there were two other cases of dysentery on service at the time. After the 46th day the temperature remained normal and the patient was discharged on September 8 apparently recovered.

Laboratory findings included a negative x-ray of the feet. Red eell counts ranged from 3,500,000 to 4,180,000 and white counts from 20,000 with 91% polynuclears, to

HOSPITAL DAYS

Chart showing relapses of temperature and days upon which treatment was given

8,500 with 69% polynuclears during the last elevation of temperature. The lowest haemoglobin reading was 57% (Neimyer) on July 5th; the blood Wassermann was Dark field examination of the blood from incised skin lesions and from the neighborhood of the wound, taken at the time of the 2nd and 3rd exacerbations, failed to show the spirachete, nor did guinea pigs inoculated with blood from skin incision or mice with venous blood show any abnormality.

The patient was treated in accord with the present accepted method, with the object of destroying the spirochete. Three intranssesslar injections of sulpharsphenamin were given, the first, 0.1 gm. at the end of the first rise in temperature occurring after admission, when the diagnosis was made.

Inasmuch as one never knows how many doses will be required to effect a cure, it seemed wise to defer the second dose until another exacerbation occurred when 0.13 gm, were given. A third injection of 0.1 gm, during the third paroxysm was followed by recovery.

Dosage can be based upon body weight: 0.01 gm. per

MEASLES IN FOUR CENTRAL NEW YORK COUNTIES FOR 1932* By FREDERICK W. SEARS, M.D., SYRACUSE, N. Y.

7 O attempt to prevent measles except in baby institutions and among other children under ithe age of three years is a waste of time and energy. The only way in which active immunity can be secured for measles, at the present time, is through the individual having the disease. Until we are able to produce artificial active immunity against measles our efforts should be devoted to preventing the serious results which frequently occur in neglected eases.

Measles in itself rarely ever causes death, yet in the State of New York hundreds of children die yearly from this disease. During the last seven or eight years in the State of New York, less attention has been given to the prevention of measles, and more attention given to the actual care of the cases. This has resulted in a considerable lowering of the death rate.

Our efforts at the present time should be exerted in utilizing all methods tending to lessen the complications and the prevention of fatal results. To get all cases of measles reported is the first essential object to be obtained, and every means to this end should be utilized. Educational methods will bring the best results. Perhaps the best publicity is through the daily press when

Read at the Annual Meeting of the Medical Society of the State of New York, at New York, N. Y., April 4, 1933.

properly presented in a plain manner to the people, Personal contact by nurses and physicians is better than pamphlets, although pamphlets properly distributed and explained by them do much toward instructing the parents.

In a fairly recent outbreak we sent a mimeographed letter to all parents in the city who were known to have children under the age of three years. There were no deaths during that outbreak. Placarding of houses tends toward concealment of the cases, and rarely does any permanent good. Among certain foreign communities the placards serve more as an invitation than as a warning as many of these people believe in exposing their children at an early age to this disease.

Publicity to be effective must be as far as possible in advance of the outbreak. Therefore, we should so far as in our power anticipate outbreaks of measles in order to warn parents against its dangers.

Early in the year 1932 it became evident to us that measles was about to occur to a considerable extent in the central New York district of which I have charge. In each threatened community it was my purpose to call on the health officer and discuss with him the best possible means of meeting the situation in his particular district, and in

most cases newspaper editors were only too glad to cooperate with us, and give us considerable

space for this purpose.

Early in March we held a conference of the health officers of my district at which conference the sole subject for discussion was that of measles; and splendid papers were prepared on the various phases of its control. This, we believe, did much toward preventing serious complications from this disease. At this meeting the subject of immune serum, parental blood and publicity were thoroughly discussed. Parents were to be urged to prevent exposure of children under three years of age, and in the event that measles did occur among any of their children, the child should be put to bed, isolated in a room by itself, visitors excluded, in order to prevent intercurrent infection.

Measles like many other respiratory diseases renders the patient very susceptible to intercurrent infection. The nasal cavities become blocked, the delicate columnar cilliated epithelial cells lining, the lower border of the larynx and the trachea become paralyzed. These delicate cillia can no longer inhibit bacterial infection, and an open road is left for infection to enter the deeper respiratory structures. Furthermore, in children under three years of age the protective glandular structures are poorly developed.

Owing to the fact that the very early stage of measles is the most contagious, little value by quarantine or isolation is obtained for the purpose of preventing others in the family from contracting the disease. It should be emphasized on the part of the parents that the isolation in a room by themselves with the exclusion of visitors is solely for the protection of the individual. It would be rare indeed for a person so isolated from the very beginning of the febrile condition to develop any serious complications. Proper home care is to be preferred to hospitalization except in cases where the complications have already occurred.

Early in the outbreak in my district we had an unusual opportunity to secure human immune serum of a very potent type. In the town of Seneca Falls ten young men between the ages of eighteen and twenty-two developed measles, and I was able to secure from them on a specified date, sufficient blood to yield 1215 cc. of excellent serum. This serum was freely used for delicate children under three years of age as early after exposure as possible in order to postpone the attack to a later period of life. Forty-three children were given this serum, and of these forty-three in thirty-five cases the measles did not develop. In seven in whom measles did develop five cases were mild and two classified as moderate. State Laboratory reports that the percentage of those completely protected was distinctly higher than the average for the State, due probably to

its early administration and the potency of the serum.

Another very excellent therapeutic measure used was the administration of parental blood to older children as nearly as possible on the 5th or 6th day after exposure, for the purpose not of preventing the disease but to so modify it as to allow them to obtain their immunity without risk of life or complications.

The line of procedure above stated was carried out very thoroughly throughout the entire district with the result we believe that nearly all of the cases were reported, many of the mothers reporting directly to the health officer when their children were taken ill, even though they had no physician. We were thus able to instruct these mothers as to the best procedure to follow; which instruction was greatly appreciated.

There were reported in the district during the year 1932, principally in the first eight months of the year, 10,544 cases of measles, with only nineteen deaths, a rate of 1.8 percent per one thousand cases. This, we believe, to be a much lower death rate than has been previously reported for this number of cases. The lowest previous rate for the State as a whole, outside of New York City, was 3.1 per thousand cases in 1931.

Perhaps the greatest factor in securing this low mortality was the absence of outbreaks in baby institutions. Due to the excellent work of Dr. Godfrey, during the past seven or eight years, our institutions have been wonderfully protected. In one of these institutions in Syracuse, which formerly furnished our largest percent of deaths from measles, not only were there no deaths, but no cases occurred in the general institution, although one family of children developed measles after its arrival in the quarantine room but so excellently was the quarantine maintained, that not a single individual in the main building was exposed to this disease.

The Syracuse Health Department has been doing excellent work in the control of the complications of measles for several years past which has resulted in an exceedingly low death rate.

Another feature which I believe is of great importance was the fact that very early in the outbreak we started a pin map, using different colored pins for the different months. This pin map was checked up daily and gave us valuable information where the disease was prevalent. On this pin map, which I will show on the slide, it was shown that we could practically anticipate the length of time the outbreak would continue in a community of a given size.

In villages of five or six thousand inhabitants the outbreak covered a period of ten weeks. In villages of slightly less population, nine weeks. In small villages and townships practically the entire susceptible population developed the disease

In the City of within a period of five weeks Syracuse, which has the largest population in my district, the disease practically ran its course in five months, reaching its highest activity about the third month

The development of the centralized school system with its numerous buses has idded very greatly to the danger of exposure of these highly communicable diseases

In one small township in which twelve small schools lind been consolidated into one central school, at the opening of this school in September one of the children who rides in one of the buses was in the early stage of measles, and within five weeks, not only the non-immune school population but practically every susceptible person in this township developed measles. No complications occurred among these cases as the human immune serum was freely used for all delicate babies under three years of age and excellent care was munitained in the other cases. In this township. having a population of 1252, 126 cases occurred within a period of five weeks from the time of the first exposure. These cases were of all ages including adults, preschool and school children

It might be interesting to analyze the cause of deaths among the ninetcen who did not recover

Nine of these cases were under one year of age

1 R B, nine months old, ill six days-no adequate

care family mentally defective

2 L. W, eight months colored illiterate no care

3 Q T, 113/2 months old lack of medical care until

too late, too poor to have a physician—pneumoma
4 F B, ten months clean home, mother ignorant of proper eare

5 R S eight months died of convulsions due to in testinal trouble—measles diagnosis hearsay
6 I V, under one year Doctor not called until day

of death-died of pneumonia

7 A S, three weeks old poor home low intelligence 8 R P under one year died in Crouse Irving Hos pital pneumonia, only lived a few hours after entering the hospital

9 E. P under one year, died in Syracuse Hospital, poor care previous to entering hospital diagnosis doubt

Of the ten one or over

1 E B, six years old, elcan home middle ear dis

arge meningitis one week later 2 C O, ten years old eongenital idiot, feeble

minded family, poor care broncho pneumonia
3 R H twelve years old mental defective, bronchopneumonia, had measles six years previous

4 B C twenty months child not isolated poor care,

taken out during illness-developed pneumonia

5 M P four years old-ignorant Polish family, re

fused cooperation of doctor 6 M C three years old-child not put to bed, in adequate care, broneho pneumonia

7 A C., twenty months old, care not good before entering hospital, mother on welfare work, broncho-

8 P W, fifteen years of age developed meningitis, good home care, severe type of disease

9 E M, ten years old, delicate child severe measles discharging car, mastoditis and meningitis 10 C B ten years old measles fourteen days mastoditis cerebral spinal meningitis good eare family well-

to-do It is apparent from the above cases that only two of the nineteen children who died received anything like adequate earc

From the above our conclusions are as follows

First Intelligent care and nursing in the home probably afford our best method of treatment

Second The use of human immune serum to postpone the attack in delicate babies under three years of age is of great importance

Third The use of human parental blood should be encouraged and should be used in all severe types of measles for the purpose of lessening the severity of the attack and yet allow the patient to acquire imminity

Fourth Placards tend to discourage reporting and therefore should not be used excepting among

people who will not cooperate

Fifth Early publicity, both by newspapers pamphlets and home visits, are of great importance in the prevention of complications in measles

Sixth All baby institutions should be carefully guarded against exposure to measles and should the disease occur, human immune serum should be given freely to all delicate babies

HYPO- AND HYPER-DYNAMIC HEARTS

By ALLEN W HOLMES, MD, WATKINS GLEN, N Y

TUCH has justly been written about the size and outline of the heart We feel that too little attention has been given to the fundamental force of the contractions Their evaluation necessitates closer cooperation with the cardiologist for, if we are to get most out of our study we must have first some idea as to the basic information he de-Sires In other words what is it the clinician

*Read at the Annual Meeting of the Med cal Soc ety of the State of New York at New York N Y on April 4 1933

Fluoroscopically, we have a means of, literally, holding the heart in our hand to study the amplitude, and character of the contractions of the various chambers This information should be weighed and recorded on the orthodiographic sheet in a manner to make it available for the cardiologist, as well as for our future comparison during the course, and treatment of heart disease This can be done under the captions of hypo- and

hyperdynamic chambers, qualified by the numer

wishes to know, and how far can we help him

als 0 to 4, just as we do for the peristalsis of the stomach. The purpose is to correlate the dynamic character, its force or its inefficiency with the size, rate, and clinical picture.

It means that the roentgenologist and cardiologist must meet, on a common ground, to study the pathological physiology of the heart. And it means that the radiologist must be familiar with the abnormalities, and their interpretation.

To begin with, the commonest heart problem is that of hypertensive diseases. Increased periphereal resistance in the arteries, arterioles, and capillaries produce a slight myocardial dilatation. This stretching of the muscle fibres of the heart causes them to contract more strongly. The result is an increase in the size of the individual bundles, or hypertrophy. The outstanding example of this is essential hypertension. Radioscopically, the left ventricle, and to a lesser degree, the entire heart action, would be hyperdynamic.

As the process advances, and these small dilatations and hypertrophies increase with the load, a corresponding increased hyperdynamic action would be expected. More character, vigor, and amplitude belong to good compensation. However, after the maximum has been reached, the myocardium begins to be embarrassed by its load. We find it making more frantic efforts to do its job. Its action then becomes more jerky, radioscopically. This may be magnified and made more apparent by slight exertions. With the advent of dilatation and myocardial weakening, the contractions become more and more hypodynamic, inefficient, and characterless. Finally, with more complete dilatation or failure, they become almost imperceptible. Fluoroscopically, then, the difference between a well-compensated hypertrophied heart, and a dilated and failing myocardium, is the difference between a hyperdynamic and a hypodynamic action.

Between this essential hypertension condition and arteriosclerosis, there is a more or less arbitrary transition. In the latter, there is a gradual increase in the periphereal resistance due to a general hardening and tortuousness of the vessels. The aorta becomes dense, atheromatous, wide, and inelastic with a prominent knob. The heart, especially the left ventricle, adapts itself by a moderate hyperthrophy and increased dynamic action. The amplitude of the contractions is fairly normal for the degree of aortic changes.

Usually, over a period of many years, these changes carry on with more or less hypertrophy, and a fairly marked hyperdynamic heart. The development of lagging undulations of the ventricle, would make us more careful of our prognosis and recomendations for treatments. Very often the decrease in the functional energy of the heart is disclosed by a feeble action developing along the ventricle. It contrasts with the previous hyperdynamic contractions just as the tired

punch of a boxer becomes apparent. They may be the forerunner, and accompany, myocardial incompetency.

Let us suppose, however, that the coronary vessels become prematurely and excessively sclerosed. This causes an ischemia with degeneration, and atrophy of the muscle fibers. There is a fibroid replacement with contraction of the scar tissue. The result of this coronary sclerosis is an absence of the hyperdynamic hyperthrophy. Rather, we get a small hypodynamic inelastic heart from this lack of oxygen, nutrition, and poor musclature.

Willius has, very recently, called attention to the fairly close paralellism between the degree of coronary, and of aortic sclerosis in a large series of postmortems. It is also recognized, that the peripheral vascular changes bear an accompanying relation to coronary sclerosis. We feel that a fairly definite entity exists where these distal vessels show changes—where we have a dense inelastic sclerosed aorta, and where we have a small hypodynamic heart with the x-ray. This, occurring between 40 and 55, would be strong presumptive evidence of coronary disease, and would suggest excessive coronary sclerosis in elderly people.

But, very often, excessive coronary sclerosis does not set in until after some degree of hypertrophy has developed. Then the size of the left ventricle and heart will depend upon the degree of dilatation, and hypertrophy present when the excessive myocardial damage becomes manifest. The coronary sclerosis, and its accompanying heart changes, would result in the contractions becoming more hypodynamic than they previously had been. The presence of considerable, fairly healthy, hypertrophied muscle would in turn make the contractions more dynamic.

The commonest location for a coronary occlusion to occur is in the anterior descending branch of the left coronary, towards the apex. After the slump which accompanies the infarct, the myocardial recovery can be observed to improve. An intracardiac thrombus would be a handicap to the cardiac amplitude. So too, would any effusion in the pericardium. Later, the area of infarct may be such an impediment to the ventricular action, that the remaining heart muscle, if fairly healthy, becomes more dynamic in its effort to compensate for the damage. If the infarct area bulges with an annerism formation, it will be expansil. Or, if the heart dilates, its low-cred amplitude will be featured.

An inflammation of the aorta also gives us an inelastic, dense, and wide aortic shadow. However, with aortitis, there is an absence of the hypodynamic left ventricle, as seen in excessive coronary changes. Syphalitic aortic encroachment on the coronary openings could produce a hypodynamic left ventricle, were it not for its accompanying aortic regurgitation and aortic changes. Valvular defects produce their individual or combination changes. Beginning for example, with aortic stenosis, we find the left ventricle contractions showing a slowly rising and falling, powerful, bent. It is an example of Inpertrophy resulting from an increased load. It contrasts with aortic regurgitation which lars a sort of Waterhammer action. With the latter, the aorta is very expansil, and the left ventrick has an extreme change in systole and diastole. Its amplitude contrasts with the slow power of the former. The dynamics, in these conditions are going to vary with the duration and degree of involvement, and the condition of the myocardium.

Hyperthyroidism may resemble aortic regirgatation. While its contractions are expansil they may not be as extreme in their systolic and diastolic change. The rate of the heart with hyperthyroidism is apt to be more rapid. Less aortic manifestations are found and it affects both sides of the heart instead of involving clinely the left ventricle, as nortic reguigitation does with its hy-

perdynamic action

In mitral stenosis when we have a fairly pure stricture the diminished amount of blood entering the left ventricle results in a small chamber The muscle fibers are not stretched and less ef fort is required to force it on. There is no increase in the periphere il resistance, hence the left ven tricle is not very dynamic. The left auricle early shows an increase in its contractions with stretch ing and thickening hypertrophy \n intra auricular thrombus might lessen its dynamics Finally, with flutter or fibrilation, its contractions may be more or less imperceptible. The right ventriele shows hypertrophy and increased dynamics due to its increased load linless late, when it may be failing and weak

The myocardial damine which is so important in all rheumitic conditions must be considered. The clouds swelling, Aschoffs' bodies and later fibrosis tend to lessen the dynamics of the muscle Generally speaking a rapid heart action causes a lessened inflow by shortening diastole and a lessened output results. This produces a smaller systole and diastole excursion.

The frequent pericardial involvement with fluid in rheumatic carditis coronary occlusion and tuberculosis, will produce a sort of billotment impulse. If great in amount the beat may be practically invisible. Obstructive adhesions may give rise to a marked condition of dilutation and hyper.

trophy In fact, these may cause some of our largest hearts, which during their development, have hyperdynamic contractions. Where there are adhesions between the two layers of the pericardium, a tugging of adjacent structures, which become accentiated by changes of respiration or position may be noted. Pericardial fibrosis, with restriction and limitation of the heart action, becomes of especial importance with the advent of surgery for its release. Definite in-tugging of the ribs and interspaces may necessitate release.

Fatty hearts due to their myocardial adipose infiltration, and pericardial fat especially, about the apex later with degeneration, are hypodynamic. This is also true of toxic degenerations, as after acute infections like diptheria and influenza. The peristrilic punch of the myocardium is definitely subnormal. In the various aenemias we may also get a late degenerative myocardium, resulting in sluggish contractions. Earlier, the heart action may be above normal as it makes desperate efforts to pump the blood around fast enough to compensate for the diminished quality.

and quantity of the blood

From this somewhat abbreviated review of the dynamics involved in certain heart evaluations, it is apparent that it is a many sided problem. We try to be of greater assistance in our Roentgen examinations. Our efforts to estimate the efficiency of the contractions have been rewarded by sufficient results to warrant their continuance. We believe that more frequent and careful fluoro scopy will add much valuable information for the cardiologist in his care of the heart problems of

DISCUSSION

Dr Loun Laugeres Bishop, Ir—All of uwho do cardiac fluoroscopy have constantly wondered whether it were possible to gauge functional efficiency of a given myocardium from watching the degree of excursion of the chambers of the heart under fluoroscopy

There is one condition where the heart excursion is definitely diminished and that is in percardial efficient. Here the contraction of the heart are usually small and hardly noticeable

One can often gain some useful information concerning the rhythm in studying a given heart

by fluoroscopy

today

The terminology—hypodynamic and hyperdynamic contractions—which Dr Holmes has given us is certainly a useful one

GRANULOPENIA

A Case Report

By THOMAS H ARGUE, M D, and RUDOLPH J SHAFER, M D, CORNING, N Y

HULTZ¹ first described the disease known as agranulocytosis in 1922 Since then many cases have been reported and various

names have been suggested as it has been found that this nomenclature is inaccurate Schilling² suggested the term malignant neutropema One

that seems satisfactory is granulopenia, introduced by Kracke.8

Granulopenia is an acute or chronic disease in which the granulocytes are decreased or are entirely absent in the peripheral blood stream.

In normal healthy adults the leucocytes number from 6,000 to 8,000 to the cu.mm. of blood. Schilling⁴ has classified the leucocytes into three groups, granulated leucocytes or granulocytes, lymphocytes and monocytes. The granulocytes are subdivided into (a) basophilic leucocytes, which form 0.5 per cent of the cells; (b) eosinophilic leucocytes, 3 per cent; and (c) neutrophilic leucocytes, 67 per cent. The lymphocytes form on the average 23 per cent of the leucocytes. The monocytes are the large mononuclear and transitional forms, and are present to about 4 to 8 per cent.

In acute cases of granulopenia the count may fall to 100 leucocytes per cu.mm. The differential count shows a marked decrease or total absence of granulocytes. The hemoglobin and red cell count rarely show any change.

The etiology of the condition is unknown. Kracke⁵ believes that it is primarly a dysfunction of the bone marrow produced by some toxic agent associated with the benzene ring. Radium, x-ray, and arsphenamine may also produce acute granulopenia. Sepsis does not seem to be a causative factor, but rather secondary to the granulopenia.

The age incidence is about forty to fifty years, and is more frequent in women than men. It seems to occur in all classes of life and occupation.

In acute granulopenia the onset is usually preceded by vague symptoms of fatigue and weakness, followed by chills, fever, and sore throat. Many of the cases reported show ulcers in the anus or vagina. In the throat the ulceration usually attacks the tonsils, and a membrane may form in which Vincent's bacilli and spirilla are found.

Various forms of therapy have been advocated but all have seemed to be of little value. The use of pentucleotide (nucleotide K-96) first prepared and used by Jackson, Parker, Rhinehart and Taylor, seems to accomplish most. Blood transfusions and irradiation are recommended.

CASE REPORT

Mrs. Ida F., age 61, first seen at her home on July 13, 1933. She complained of pain in the left side and a rash in the same radius

in the same region.

The present illness began three days previous, with fever, constipation, malaise and pain around left lower ribs. The past history included the usual diseases of childhood and for the past few months slight dyspnoea and precordial pain on exertion. Family history negative except that several members of her family had had herpes zoster, one brother and sister died of angina pectoris. Her husband and four sisters were living and well.

The patient was well developed and nourished. Scalp, eyes, ears, nose, and tongue were negative. The teeth and gums were negative except for a slight inflammation of the gum around one tooth, which had a gold cap. The heart sounds were a little faint, otherwise the heart was normal. The lungs and abdomen were normal. Pelvis and rectal examinations were negative except for a few small hemorrhoidal tabs. Beginning about one inch to the left of the spine and involving eighth and ninth dorsal segments were the typical lesions of herpes zoster. Her temperature was 100.6°, pulse 90. Urinalysis negative. Under treatment with calamine lotion and amidopyrine this condition gradually cleared up.

Four weeks later she was taken suddenly with severe precordial pain, labored respirations and marked cyanosis of all mucous membranes. The temperature was 98.6°, pulse 116. Her heart was fibrillating, and there was distension of the abdomen. She was admitted to Corning Hospital. The blood showed hemoglobin 98%; erythrocytes, 5,250,000 per cu. mm.; leucocytes, 8,100; polyneutropliiles, 54%; transitionals, 3%; lymphocytes, 43%. Urine was normal. An electrocardiogram showed a typical curve of eoronary occlusion. She improved daily under treatment but one week later was suddenly taken with a sharp pain under the left shoulder blade accompanied by a harsh dry cough. Next morning a circumscribed area of impaired resonance and bronchial breatling was found, and her temperature was 102.4°, pulse 116, respiration 32. The cough produced a small amount of sputum, flecked with blood. Later, a pleural friction rub could be heard. Blood showed hemoglobin, 50%; erythrocytes 3,970,000; leucocytes 18,000; polyneutrophiles 93%; transitionals 2%; lymphocytes 5%.

During the next five days the symptoms and signs of pulmonary infarct cleared up. At noon on August 26th, her temperature rose suddenly to 100.4° though her only complaint was slight soreness in the rectum, which she ascribed to enemata. About 3:00 P.M. she began to complain of a severe sore throat, and she became drowsy and cyanotic. Temperature rose gradually to 105°. Next morning in addition to the sore throat she was nauscated and complained of soreness in the rectum. There was a marked injection of the blood vessels and generalized swelling of the tissues around the pharynx. Rectal examination showed several small ulcerated areas just inside the anal margin. Blood examination at 4:00 P.M. showed a leucocyte count of 1200 per cu. mm. One hour later complete blood examination showed hemoglobin 70%; erythrocytes 4,130,000; leucocytes 875 per cu. mm. and 100% lymphocytes. Platelets seemed to be increased. A diagnosis of granulopenia was made and confirmed by Dr. S. E. Conklin of the Robert Packer Hospital, Sayre, Pennsylvania. Following the intravenous administration of neo-arsphenamine 0.6 gm., the temperature dropped to 103°, but during the night it rose to 106°. Early the next morning the blood showed hemoglobin 54%; erythrocytes 5,150,000; leucocytes 550 per cu. mm.; lymphocytes 100%. Following a transfusion of 500 cc. whole blood, her general condition seemed better. Temperature remained at 106° however. Pulse varied from 100 to 108. She became restless and had several involuntary bowel movements. Death occurred about 4:00 P.M. Autopsy could not be obtained.

Comment

This was an unusual case of a woman, who had always enjoyed good health, taken suddenly with a mild attack of herpes zoster from which she made an uneventful recovery, only to have successive attacks of corgnary occlusion and a pulmonary infarct which she survived; and then died from an acute, granulopenia.

HEARING IMPAIRMENT IN SCHOOL CHILDREN

By R. BEATRICE ROSSELL, M.D., BUFFALO, N. Y.

ECENTLY our attention lias been focused on the child with a hearing difficulty, not sufficient to be classified among the deaf, but with an impairment sufficient to affect its present and future welfare.

Early recognition of children so handicapped has been very difficult, in public schools. The watch tick test, the tuning fork, and the whisper tests were not practical enough to be employed in the examination of a large number of children. Besides, the many variations and inaccuracies rendered them useless for comparative purposes. Consequently these tests were employed only for examination of cases referred because of a suspected hearing loss, and not for the purpose of detecting a hearing loss not yet discernible in ordinary conversation. Slight impairments are not recognized by either the child, teacher or parent. Often a child is condemned as listless, inattentive, troublesome and dumb because the teacher fails to recognize that the child is a problem only insofar as his hearing is concerned.

With the use of the 4-A Audiometer as recommended by Dr. E. P. Fowler and Harvey Fletcher of the Bell Telephone Laboratories, the problem of early detection of hearing impairment in school children has been greatly simplified and unified. As many as forty children can be examined together in a period of fifteen to twenty minutes. This method is now employed both here and ahroad with satisfactory results.

During the fall of 1931-32, with the co-operation of the Educational and Health Departments, a survey was made of ten public schools of Buffalo, N. Y. These ten schools consisting of 6,781 children from the 2nd half of the second grade to the eighth grade were

chosen as representative of the various social and racial groups of the population of Buffalo.

The incidence of impairment of hearing has been reported to be less in the economic independent and educated classes than in the less fortunate and foreign classes. This, perhaps, is due to better and more specialized care during the first seven or eight years of life. In private schools an incidence of 3% or less has been reported. In public schools the average is from 7 to 15%.

The various localities differ. Table I illustrates the wide variations.

TABLE I	
Percentage of Incidence	
Ann Arbor	10-20% 8 00 13.00 1.33 17.00 1 00 14 40
New 10fk. Rhode Island St. Louis San Francisco Tennessee Worcester	2.50 4 50 6.00 2-3 0 3.50 2.70

In Buffalo the local variations were: (Table II.)

In schools where the economic conditions are poor, where there is little or no medical care, we have an incidence of 5-9% hearing impairment. In schools of mixed classes we have an incidence of 3-5% H. I. In schools in communities where medical care is no worry and adequate we find an incidence of 2.5-3%.

The average incidence is 5.84% with a hearing impairment of 12% or above hearing loss. 5.78% have a hearing loss of 9% (borderline

		TABLE	EII						
Perc	ENTAGE OF INC	CIDENCE 1	N THE	Varidus	Schoo	LS			
School No No. Tested No.: No. No. Per Communication	765 617 74 29 77 31	29 675 31 20 4.3%	42 943 57 73 5.8%	51 647 28 14 4.3%	58 845 75 79 9.3%	62 773 23 24 2.9%	63 607 15 4 2.5%	75 675 53 63 8.8%	50 234 14 3 5.98%

cases) 11.62% of the 6,781 cases examined show a hearing loss of 9% or over.

The 4-A Audiometer is not an instrument of precision for the diagnosis of ear conditions, but an instrument which facilitates the tabulation of the hearing capacity of the individuals examined. From the individual records the normals can be separated from those showing defective hearing or those in need of further check-up and otological examination. The 4-A Audiometer is also useful in determining the effects of treatment and for checking up gradual changes in progressive deafness, when a large number of school children are to be examined.

Any degree of loss is of educational as well as of medical importance. However, in this survey only the cases showing a loss of 12% or above received a complete otological examination. We considered a careful history of the case and a complete ear, nose and throat examination essential to determine the nature of the difficulty, before a prognosis and a disposition of the case was made.

In the history, the question of earache, aural discharge, head colds, sore throats, and infectious diseases was especially noted. Earache was not a common or persistent symptom accompanying ear disease. A history of earache was obtained in 138 cases of the 399 cases showing unquestionable involvement. A history of head colds was obtained in 236 and sore throat in 164 of the 399 cases of affected hearing. (Table III.)

otitis. One case developed after a skull injury. Two cases were diagnosed Otosclerosis, one Tuberculosis of middle ear and two cases were recommended for Wassermann test. Two hundred and nineteen recommendations were made for removal of tonsils and adenoids and 95 had had their tonsils and adenoids removed thru the recommendation of the family physician or ear specialist. There was a prevalence of hypertrophied or diseased tonsils and adenoids among the children showing defective hearing. One active case of mastoiditis was discovered and one acute otitis media; both were referred for immediate treatment.

Briefly, the disposition of the cases included a program of educational guidance and advice to the parents.

The educational advice was based on the extent of impairment and the progressive tendency of the lesson. Children with only a slight degree of loss are assisted in the regular class room by being placed in a front seat either to the right or the left of the teacher depending on the ear involved or in the center of the room when both ears are involved. The teacher is advised to face the light when speaking to the class so that her lips are clearly visible. These children soon acquire the habit of watching the speaker's lips and thereby assist their ears with their eyes. Others are in need of further assistance in special classes and in a certain percentage lip-reading instruction becomes absolutely necessary.

Earache	26 1 17 45 1	7 7	20 6 33	17 3 23	24 10	7 10	3 8	18 7	6 9	138 84	
Head Colds	45 1 29 1 68 2	7 19	23 21	12 28	28 23 36	19 7 20	3 12	29 38	12 4	236 164 281	

otolaryngological examination sisted of the examination of the auricle for deformities; the external canal for foreign bodies, cerumen, discharge, polipy or granulations; the drum for color, retraction, motility, scars, calcium deposits, perforations; the mastoid process for tenderness or scars of previous operations. Tuning fork tests were made when indicated. The naso-pharynx was examined for the presence of obstruction, secretions, presence or absence of tonsils and adenoids and their condition. The sinuses where trans-illuminated and the Eustachean Tube ostia examined when indicated. (Table IV.)

Of the 399 cases of 12% or over hearing loss 65% were due to catarrhal or non-suppurative conditions and 26% due to suppurative

In some cities a loss of 9 to 12% is referred for special care by the teacher. A 12-15% loss calls for regular lip reading and regular class work and a 15-20% for special training.

It is difficult to say just how many sensational units of loss establishes a need for lip reading. Each child must be given individual consideration. The history of the case, the progressive character of the lesion, the conditions of the other ear and its chances of involvement and many other factors must be taken into consideration. When, after analysis of the case the prognosis is poor the child should be fortified with lip reading immaterial of the degree of loss.

In this group it was found that lip-reading instruction was essential in 22 cases or 6.59%.

Another group of 26 or 745% would be greatly benefited in keeping up with their class work, if assisted with instructions in lip reading 1 total of 48 or 14% were recommended for lip reading instructions

Recommendations for otological care were referred to the parents and the school nurse who follows up the case by home calls if neces sary, to advise the parents and assist in pro curing medical care, when parents are unable, thru the dispensaries

Children with perforations of the drum membrane were advised against swimming or div

A number of children were recommended for examination with the 2-A Audiometer

SUMMARY

1 The difficulties heretofore encountered in the examination of school children for defec tive hearing have been eradicated by the 4-A Audiometer now generally employed

2 Early medical treatment and care during the early years of life reduce the incidence of hearing defect. In public schools the figures run higher than in private schools centage of incidence in the various cities employing this method ranges from 1-20% Buffalo the percentage is 578% borderline and 5 84% for 12% or above hearing loss

3 All cases showing a defect of 12% loss or over received a complete oto laryngological examination

4 This group examined were classified ac cording to percentage of hearing loss, medical

and educational history and their physical defects

5 Lip reading was considered essential for 659% of the children examined group of 26 cases or 7.45% of the total number of children examined, were recommended for lip reading as a special fortification against further loss

RECOMMENDATIONS

1 An Audiometer Reading of the hearing of every school child is a helpful record in de-

termining educational progress

2 All children who have been absent from school because of ear, nose and throat conditions or infectious disease such as scarlet fever especially should be referred for otologieal evainination and Audiometer reading. Also all repeaters, cases of apparent stupidity, mattention, all faulty speech cases and problem children should be referred for examination

3 Parents, teachers and principals should be informed of the eauses of ear disease and instructed to recognize a beginning deafness so no time may be lost in instituting mensures against the tragedy of deafness which often follows neglect

4 Lip reading instruction is strongly urged for all cases who have acquired an unremedial hearing impairment progressive in character

5 A united effort of all authorities, otologists, teachers, social service workers and parents is essential to continue this substantial beginning toward eliminating total deafness among our school children

cases) 11.62% of the 6,781 cases examined show a hearing loss of 9% or over.

The 4-A Audiometer is not an instrument of precision for the diagnosis of ear conditions, but an instrument which facilitates the tabulation of the hearing capacity of the individuals examined. From the individual records the normals can be separated from those showing defective hearing or those in need of further check-up and otological examination. The 4-A Audiometer is also useful in determining the effects of treatment and for checking up gradual changes in progressive deafness, when a large number of school children are to be examined.

Any degree of loss is of educational as well as of medical importance. However, in this survey only the cases showing a loss of 12% or above received a complete otological examination. We considered a careful history of the case and a complete ear, nose and throat examination essential to determine the nature of the difficulty, before a prognosis and a disposition of the case was made.

In the history, the question of earache, aural discharge, head colds, sore throats, and infectious diseases was especially noted. Earache was not a common or persistent symptom accompanying ear disease. A history of earache was obtained in 138 cases of the 399 cases showing unquestionable involvement. A history of head colds was obtained in 236 and sore throat in 164 of the 399 cases of affected hearing. (Table III.)

otitis. One case developed after a skull injury. Two cases were diagnosed Otosclerosis, one Tuberculosis of middle ear and two cases were recommended for Wassermann test. Two hundred and nineteen recommendations were made for removal of tonsils and adenoids and 95 had had their tonsils and adenoids removed thru the recommendation of the family physician or ear specialist. There was a prevalence of hypertrophied or diseased tonsils and adenoids among the children showing defective hearing. One active case of mastoiditis was discovered and one acute otitis media; both were referred for immediate treatment.

Briefly, the disposition of the cases included a program of educational guidance and advice to the parents.

The educational advice was based on the extent of impairment and the progressive tendency of the lesson. Children with only a slight degree of loss are assisted in the regular class room by being placed in a front seat either to the right or the left of the teacher depending on the ear involved or in the center of the room when both ears are involved. The teacher is advised to face the light when speaking to the class so that her lips are clearly visible. These children soon acquire the habit of watching the speaker's lips and thereby assist their ears with their eyes. Others are in need of further assistance in special classes and in a certain percentage lip-reading instruction becomes absolutely necessary.

RENAL MANIFESTATIONS OF HYDATID DISEASE

Report of a Case

By JAMES H. BORRELL, M.D., and JOHN M. BARNES, M.D., BUFFALO, N.Y.

From the Departments of Urology and Roentgenology, Millard Fillmore Hospital, Buffalo, New York.

YDATID disease is that condition in which the intermediate developmental stage of the dog tape-worm, Taenia Echinococcus. involves the tissues of man or The adult worm measuring food animals. approximately one-eighth inch in diameter selects as its host members of the dog family: the wolf, fox, jackal and domesticated dog. A heavily infested host may harbor many thousands of worms in its intestinal tract; and since each worm is capable of producing thousands of ova, the feces of these infected animals even in minute amounts, may be highly infectious. Man and food animals. particularly sheep, act as the intermediate hosts. Upon the ingestion of ova, either directly by way of contaminated food or more rarely through dust inhalation, the intermediate developmental stage of the parasite is The ova pass into the stomach instituted. where their outer covering is softened or partly destroyed by the gastric juice. Doubtless many ova are either destroyed or rendered non-viable in this process. Those escaping to the alkaline small bowel liberate embryos which invade the intestinal wall to reach the portal or more rarely the vena cava radicles.

In this manner the embryos gain access to the circulation and, from this point on, chance and vascular anatomy decide the tissue or organ involved. No definite tissue selectivity seems to characterize this parasite. The high frequency of liver and lung involvement seems to depend entirely on the former's intimate relation with the portal circulation and the well recognized filter action of the latter.

Where the embryos settle out of or are blocked in the circulation, they shed their original hooklets and develop into a vesicular worm.

De Tarnowski's¹ description of this phase of the parasite's development is quite concise. "On reaching its ultimate destination, the six original hooklets disappear and a vesicular worm develops surrounded by a pericystic membrane which represents the normal reaction of inflammation of the organ in which the parasite is cradled. It is therefore correct to speak of the invading host as having two surrounding layers, a capsule and an endocyst. This constitutes the second or encysted stage of the echinococcus. In the primary or mother vesicle, daughter vesicles or cysts de-

velop. Between the lamellae of the cyst wall of the mother vesicle there is produced an accumulation of granules that is surrounded by a cuticle and this becomes the center of a new system of stratification. While the number of strata increases, the cavity enlarges and the liquid content becomes clarified. If the daughter cysts grow, the wall of the mother cyst is distended by means of herniated sacs until it bursts and its contents are freed."

Regarding the formation of daughter cysts, Brailsford² says, "It is now generally believed that the formation of daughter cysts is related to the trauma of the parent cyst, for where the parent cyst is protected, as in the bony thorax or the skull, it is frequently single."

The rate of cyst growth varies considerably, depending on the host and site of implantation. In silent areas ten to fifteen years may elapse between the time of infestation and the occurrence of clinical symptoms. The growth is slow and relentless, and in the majority of cases leads to a fatal termination. Occasionally, spontaneous cure occurs. This is particularly seen in those cases which communicate externally following rupture into a bronchus, the renal pelvis or the urinary bladder. The cure in these cases appears to result not alone from evacuation of cyst contents, but from the destructive effects of superimposed infection.

When food animals develop the disease, they frequently come to slaughter before sufficient time has elapsed for a fatal termination. Under such circumstances, if the cysts are ingested by any of the dog family, the developmental cycle of the worm is completed. Brailsford describes this phase of the cycle as follows, "The parasitic cysts being common in food animals and not affecting the sale of the meat of the animal, odd cysts are cut off and thrown on the floor by the butcher, while trimming the viscera for sale. thinks no more of the cyst than he would of a clot of blood or other waste fragment. Further, sheep's lung which one has sometimes seen so extensively packed with cysts that little normal tissue remains, is not sold for human food. They are put on one side as food for cats and dogs. Again slaughterhouse refuse is sometimes used for manure, being spread over fields, to the joy of all the dogs of the neighborhood. Upon ingestion of

cyst material, the contained seolices become attached to the intestinal wall and develop into the mature worm discharging its myriads of ova for further reproduction of the cycle."

American eases of hydatid disease are in the great majority of cases imported. They occur for the most part in foreign born southern Europeans. Fortunately the incidence of the disease in North America has remained quite low. In this connection, however, it is well to take eognizance of a statement of Craig and Lee-Brown,3 "If the encouragement of wool-growing in the United States of America and Canada continues, we feel sure that the next generation of surgeons in these two great countries will have more opportunities of studying the manifestations of hydatid disease than their predecessors had."

Throughout the world the organ incidence of hydatid disease appears to be about the same, liver 70%, lungs 10%, spleen 2.5%, kidney 2.5%, other abdominal organs 5%, muscles and cellular tissues 5%, brain 5%, bone 1%.

The ease which we report showed involvement of both kidney and liver. The primary organ involvement cannot be surnised from the evidence at hand.

Present Illness

D. S., patient of Dr. John M. Mesmer, age 55, married, was admitted to the Millard Fillmore Hospital, November 30, 1930. He complained of pain in the upper right quadrant and right loin, which had been vaguely present for the past several years. During the past four to six months this pain had inereased in severity and had become more prominent in the back. At times this pain has been associated with gascous distress and nausea. There has never been any vomiting or radiation of the pain to other regions than those mentioned. One week before admission to the hospital, he passed a ropy looking. mucoid string about six inches long in the There was no further history of urine. urinary disturbance.

Past History

The patient was born in southern Italy where he lived intil about twenty years of age. During his youth in Italy, he worked as a goat herder. Since his arrival in the United States, he had always lived in or about Buffalo, N. Y. With the exception of pneumonia as a boy, and an occasional cold, he had not been subject to illness.

Physical Examination

The following positive findings were elicited. Patient was somewhat pale, showing slightly blanched mucous membranes. The abdomen appeared slightly distended with a definite fullness in the right upper quadrant. This was seen more clearly on expiration. On palpation a definite tender mass was noted in this region. It moved little if any with respiration and was situated below the liver in about the nipple line. It was not attached to the abdominal wall, but did appear to be fixed to the liver above. The mass was rough in outline, firm to touch and moderately tender. It could also be palpated in the right flank.

Rectal examination showed moderate enlargement of the lateral lobes of the prostate,

The day following admission to the hospital, an examination of the abdomen and gastrointestinal tract was performed. This examination revealed a homogeneous soft tissue density continuous with the liver density extending well down towards the right crest of the ilium. The pyloric portion of the stomach. the duodenal bulb and the hepatic flexure were displaced downward by this shadow which corresponded with the palpable mass in the right upper quadrant. X-ray examination of the chest showed a slight elevation of the right leaf of the diaphragm and a small pleural scar in the region of the seventh rib on the left side in the posterior axillary line

Laboratory Reports

Laboratory reports revealed a mild secondary anemia with a normal differential count-Blood examination showed the following:

Hemaglobin 70%: Red cells 4,120,000 White cells 8750: Neutrophiles 72%: Lymphocytes 27%: Eosinophiles 1%. Urinalysis revealed the following: Sp.Gr. 1022, alkaline reaction, trace of albumin, indican 2+, occasional leucocytes, occasional red blood cells, occasional crystals and amorphous salts, otherwise negative. Owing to the urinary findings, the patient was cystoscoped on December 8, 1930.

Cystoscopic Examination, 12/8/1930

No. 25 Brown-Buerger eystoscope used. Bladder negative for tumors, diverticula and stones. Both ureteral orifices were visualized and eatheterized with No. 6 X-ray eatheters. There was no drainage from the right side. Drainage from the left side showed a few pus cells and red blood cells and many round eells. From the bladder, the urine showed numerous pus cells and some crystals. Both ureteral eatheters were withdrawn and a No. 9 Garceau catheter inserted into the right ureter. A twenty minute P.S.P. renal function was done

and 15 cc. of drainage was recovered from the No dye was excreted from this right side. 210 cc. was obtained from the left side. kidney, accepting the bladder as left, and 20% of the dye was eliminated from this side. An attempt was made to do a right ureteropyelogram, but the dye seemed to meet with obstruction about halfway up the ureter and apparently none of the dye entered the kidney pelvis. A second attempt was made with the patient's head lowered. This time a small amount of dye could be seen permeating a large mass in the right side of the abdomen. The following day, December 9, 1930, the patient was given uroselectan intravenously. Fair visualization of the left pelvis, calices and ureter was obtained. No visualization occurred on the right. This was true in the 15, 45 and 75 minute plates.

From findings to date a pre-operative diagnosis of kidney tumor was made. The possibility of Hydatid disease of the right kidney was suggested.

The patient was operated upon December 20, 1930. The usual posterior incision extending from the lower border of the ribs to within one inch of the brim of the pelvis, was made. The right kidney was exposed and delivered and a large cyst of the upper pole was ruptured. Many daughter and grand-daughter cysts were expelled through the wound. The cyst was under such tension that various sized small cysts literally tumbled from the incision. Further investigation revealed a much larger cyst on the lower border of the liver, which seemed to be connected with the upper pole of the right kidney by extension. An attempt was made to evacuate the large mother cyst in the liver. A conservative estimate of the number of cysts of various sizes evacuated would be 500. An attempt to treat the cysts by marsupialization was made, but could not be completely achieved owing to the difficulty in reaching all sides of the cyst wall. A large drain was inserted into the fossa and the wound closed with through and through sutures.

The pathological report by Dr. Margaret Warwick Schley, Director of Pathology, Millard Fillmore Hospital, follows:

"The material removed consists of about a quart of thick, slimy, blood-tinged fluid in which are great numbers of ruptured cysts and a few which are unruptured. All of these evidently represent daughter cysts. The broken cysts show a collapsed wall which measures up to 1 mm in thickness and curls inward. The outer surface is thick, white and tough, while the inner is more delicate and glistening. Microscopic sections of these walls show them to consist of a pink-staining, formless laminated structure with parallel striae, but no cell detail or nuclei.

"In the mass of material removed are a few un-

ruptured cysts with thin intact walls which are slightly compressible against the contained fluid. Figure I. The thin walls are very tough and are broken with some difficulty. These cysts contain clear fluid in which are particles resembling granules of white sand. These quickly settle to the bottom when the fluid is brought to rest.

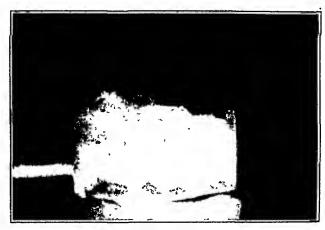

Figure 1
Cysts after Formaldchyde Fixation

"Under the microscope these particles prove to be tiny parasites with a contractile movement. Each consists of a rounded mass of protoplasm in which are great numbers of bright granules.

"At one side of the mass is a round projecting sucker surrounded by a collar or rostellum formed by a double row of tiny hooklets of two sizes. These are for the purpose of holding the sucker against the intestinal mucous membrane. The parasite has a movement which consists of a slight thrusting out and pulling in of the sucker with its bristling collar of hooklets. This movement persists for hours on a warm stage. In the free fluid are a few unattached hooklets, but these are very few because the parasites are yet alive with all of their hooklets attached."

Following operation the patient ran an intermittent septic type of temperature. Drainage from the incision was profuse and contained a large number of cysts. His appetite was poor, but the upper right quadrant pain was relieved and the mass became considerably smaller during the first few days after operation. One month following operation, the patient was discharged from the hospital. At this time, cysts were still being expelled from the sinus. He became progressively weaker at home, continuing to pass cysts from the wound and later the discharge became purulent. The patient died approximately three months after his discharge from the hospital.

Discussion

According to Kretschmer⁴ no characteristic pyelographic picture has been described in this condition. The cysts may become calcified and present as thin walled ring shadows of different

The renal pelvis may be deformed or not depending on the location of the cyst. In some instances a sub capsular cyst may mimie the

LIGURE 2 Retrograde Pselogrow The renal pelvis is displaced downward and toward the mid line. The calices are of literated and in their places.

are seen mony various sized ares apparently produced by rodude solution outlining part of the surfaces of spheres solitary renal cysts. With deep involvement of

the parenchyma pelvic deformity is an almost certain accompaniment. In the case reported, Figure 2, the renal pelvis is displaced downward

and toward the mid line. The calices are oblitcrated and in their places are seen many various sized arcs produced apparently by iodide solution outlining part of the surfaces of spheres

The difficulty in diagnosis in cases of hydatid disease vary considerably, depending on whether the case is 'open" or 'closed". In the former instance, the cyst communicates with the renal pelvis and discharges drughter cysts pieces of membrane or hooklets in the urine. In the case of passage of cysts or membrane the patients may give a history of passing grapes, grape skins or pieces of flesh in the urine. The hooklets would accessifily have to be identified micro scopically In our case the history of passing a six inch rope of mucous is quite suggestive However numerous urme examinations throughout the period of hospitalization, revealed none of the characteristic findings of hydatid disease In the closed type of the disease, no characteristic urmary findings occur. Here one must depend on a composite picture made up of nationality, history, symptomology blood findings and the various serological and skin tests

Most of the cases reported show a definite cosmophilia In our case, however, the admission and pre-operative counts showed only 1% eosmophiles

Most important in the diagnosis of this condition is the necessity of keeping its possibility in mind Finally, a word as to treatment. It is not our purpose to draw conclusions as to treatment from a single ease, but a review of the more recent articles on hydatid disease by Southern European and Australian writers would indicate that the type of treatment depends entirely upon whether one is dealing with the "open" or "closed" type Nephreetomy for the "open" and marsupialization for the "closed" types seem to be the treatment of choice

and 15 cc. of drainage was recovered from the No dye was excreted from this right side. 210 cc. was obtained from the left side. kidney, accepting the bladder as left, and 20% of the dye was eliminated from this side. An attempt was made to do a right ureteropyelogram, but the dye seemed to meet with obstruction about halfway up the ureter and apparently none of the dye entered the kidney pelvis. A second attempt was made with the patient's head lowered. This time a small amount of dye could be seen permeating a large mass in the right side of the abdomen. The following day, December 9, 1930, the patient was given uroselectan intravenously. Fair visualization of the left pelvis, calices and ureter was obtained. No visualization occurred on the right. This was true in the 15, 45 and 75 minute plates.

From findings to date a pre-operative diagnosis of kidney tumor was made. The possibility of Hydatid disease of the right kidney was suggested.

The patient was operated upon December 20, 1930. The usual posterior incision extending from the lower border of the ribs to within one inch of the brim of the pelvis, was made. The right kidney was exposed and delivered and a large cyst of the upper pole was ruptured. Many daughter and grand-daughter cysts were expelled through the wound. The cyst was under such tension that various sized small cysts literally tumbled from the incision. Further investigation revealed a much larger cyst on the lower border of the liver, which seemed to be connected with the upper pole of the right kidney by extension. An attempt was made to evacuate the large mother cyst in the liver. A conservative estimate of the number of cysts of various sizes evacuated would be 500. An attempt to treat the cysts by marsupialization was made, but could not be completely achieved owing to the difficulty in reaching all sides of the cyst wall. A large drain was inserted into the fossa and the wound closed with through and through sutures.

The pathological report by Dr. Margaret Warwick Schley, Director of Pathology, Millard Fillmore Hospital, follows:

"The material removed consists of about a quart of thick, slimy, blood-tinged fluid in which are great numbers of ruptured cysts and a few which are unruptured. All of these evidently represent daughter cysts. The broken cysts show a collapsed wall which measures up to 1 mm in thickness and curls inward. The outer surface is thick, white and tough, while the inner is more delicate and glistening. Microscopic sections of these walls show them to consist of a pink-staining, formless laminated structure with parallel striae, but no cell detail or nuclei.

"In the mass of material removed are a few un-

ruptured cysts with thin intact walls which are slightly compressible against the contained fluid. Figure I. The thin walls are very tough and are broken with some difficulty. These cysts contain clear fluid in which are particles resembling granules of white sand. These quickly settle to the bottom when the fluid is brought to rest.

Figure 1
Cysts after Formaldehyde Fixation

"Under the microscope these particles prove to be tiny parasites with a contractile movement. Each consists of a rounded mass of protoplasm in which are great numbers of bright granules.

"At one side of the mass is a round projecting sucker surrounded by a collar or rostellum formed by a double row of tiny hooklets of two sizes. These are for the purpose of holding the sucker against the intestinal mucous membrane. The parasite has a movement which consists of a slight thrusting out and pulling in of the sucker with its bristling collar of hooklets. This movement persists for hours on a warm stage. In the free fluid are a few unattached hooklets, but these are very few because the parasites are yet alive with all of their hooklets attached."

Following operation the patient ran an intermittent septic type of temperature. Drainage from the incision was profuse and contained a large number of cysts. His appetite was poor, but the upper right quadrant pain was relieved and the mass became considerably smaller during the first few days after operation. One month following operation, the patient was discharged from the hospital. At this time, cysts were still being expelled from the sinus. He became progressively weaker at home, continuing to pass cysts from the wound and later the discharge became purulent. The patient died approximately three months after his discharge from the hospital.

Discussion

According to Kretschmer no characteristic pyelographic picture has been described in this condition. The cysts may become calcified and present as thin walled ring shadows of different

DOCTORS' ADVERTISEMENTS

It takes two parties to run an advertisement in a periodical; an advertiser, and an editor of a journal. There have always been a few doctors who have violated the code of conduct of the medical profession, and have inserted paid advertisements in the newspapers proclaiming their great skill and love of suffering humanity. Such advertisements are seldom or never seen today, for the publishers of newspapers have raised their standards of advertising so that doctors who seek publicity cannot find an editor who will accept their paid advertisements.

The attitude of newspaper editors toward physicians forty years ago is shown in the following announcement which was printed ostensibly as a news item on August 13, 1893, in the New York Recorder, a morning daily:

"Doctors McCoy and Snow announce the greatest opportunity to the public that has ever been offered by any specialist in the medical world.

"This offer is in the form of a free test of their plan of treatment for the cure of catarrh and other curable chronic diseases,

"All who apply in person will be examined, prescribed for and treated upon their first visit free of all charge. In addition to this, thorough consultation and advice will be given to all who apply, without a penny to pay.

"This is a test which the patient can make use of without risking a single cent for examination, the first treatment, consultation, advice, or medicine.

"Doctors McCoy and Snow offer this free test to the public as the surest and fairest way of convincing everybody that their plan of treatment is the very best known to medical skill. It is an honest, straightforward way of becoming acquainted with the great number of persons who have blindly bought, and paid dearly for their experience."

HEALTH AND THE ECONOMIC DEPRESSION

There has been much discussion in periodicals, both medical and lay, regarding the effect of the economic depression on public health and death rates. The prevailing opinion seems to be that the rates for either sickness or death have not increased; or, if they have, the increase is regional and accidental. On the other hand, some studies have revealed an increase in the proportion of undernourished children discovered in public schools, and on this basis predictions of later ill health are made.

This general maintenance of a high standard of health during times of depression was unexpected, because poverty has previously been recognized as a leading cause of sickness, especially the more chronic forms such as tuberculosis. The reasons for the apparent anomaly are plain, and are a justification of the methods adopted throughout the nation for the distribution of medical services to all who need them.

Poverty is a potent cause of ill health because it prevents the very poor from obtaining those things which are essential for healthful living. It is highly to the credit of citizens generally that they have willingly supported public measures for providing the poor with necessities which they would not otherwise have obtained, and thereby they have neutralized the effects of poverty on health. Public officials and welfare organizations

have provided the hungry with not merely bread, but with milk and green vegetables which are essential for health, and which were formerly considered to be luxuries. No one in these modern days sees a child clothed in the rags which were the classic badge of poverty a half century ago; and no community tolerates tumble-down tenements, with their lack of sanitation. Finally there has come the realization that medical attention is as essential as food; and the services of a doctor with hospitalization and nursing, if necessary, are available at public expense. Medical service is available more readily and abundantly than ever before. Another factor is the activities of health departments both in carrying on their old lines of work and also in entering new fields, such as giving immunizations, child welfare, maternal health, and school examinations. Some public health nurses have been laid off, but the amount of preventive work done by departments of health has been increased during the depression. All these activities have had a sure effect in lessening morbidity and mortality.

What the future may bring forth is uncertain; but there is abundant evidence that the economic depression has stimulated all forms of health work to such an extent that living conditions for the poor are now guarded and controlled more carefully than ever before.

MEDICAL PROGRESS

Modern Methods in the Treatment of Nephritis .- Clifford Hoyle lists among recent additions to the treatment of nephritis modifications in diet, the use of large doses of alkalies, certain new diuretics, and methods for reducing intracranial tension in some of the acute cerebral at-Three important advances in the dietetic treatment of nephritis are: (1) Severe fluid and food restriction in acute glomerulo-nephritis, as advocated by Volhard; (2) the use of salt-restricted diets in edema; and (3) high protein diets, introduced by Epstein, for chronic nephrosis with edema. In acute nephritis the administration of fluids, and especially of milk, seems no longer to be a rational line of treatment, as the aim is to spare the kidney as far as possible. Protein and salt must be largely prohibited and the water intake should not be greater than the urinary output, but it is now recognized that restriction of protein is often harmful in chronic With the Epstein high protein diet nephrosis. patients regain strength, become less anemic and lose their edema, sometimes even completely. High protein diets should not be given when the renal activity is impaired. Intensive administration of alkalies for short periods is a valuable palliative measure for the relief of uremic dyspnea and restlessness. One or two drachms of sodium bicarbonate should be given every hour until there is relief. In an emergency it may be given intravenously as a 4 per cent solution. In acute nephritis the saline and purine diuretics are almost always useless, and mercurial diuretics are dangerous. Nevertheless, if heart failure supervenes, mercurial diuretics in certain cases are Diuretics are also useful in often beneficial. chronic nephrosis with edema. Urea, in doses of 300 to 600 grains daily for three to seven days, sometimes leads to a profound diuresis, but it is uncertain and causes intense thirst. Potassium salts may also be effective. Ammonium chloride and nitrate are often powerful diuretics, though they are ineffective when there is renal insufficiency. Calcium chloride is the least harmful and the most efficient diuretic in nephritis with edema. It may be given in doses up to 160 grains daily together with a diet poor in salt. The same diuresis may be obtained by using injections of parathyroid extract, 10 to 20 units at intervals of a week or so. The greatest advance in the field of diuretics has been the introduction of salyrgan and neptal. With these drugs good results have been obtained in chronic nephrosis; they should not be used in acute or chronic glomerulo-neph-The diuresis from a single injection may be as great as 10 liters in a previously waterlogged patient. Bismuth sodium tartrate has re-

cently been shown to have a powerful diuretic action when given intramuscularly. For the reduction of intracranial pressure in hypertensive encephalopathy, lumbar puncture, the administration of intravenous salines, and venesection are indicated.—*Practitioner*, October, 1933, cxxxi, 4.

Syncopal Attacks as a Symptom of Intussusception.—Richard W. B. Ellis, writing in The Lancet, September 23, 1933, ccxxv, 5743, states that the occurrence of sudden pallor during the attacks of pain in cases of intussusception is observed so frequently that it is perhaps surprising that the possibility of actual syncope is not mentioned in any of the standard text-books. He cites two examples of the occurrence of this symtom as a complication of intussusception. A child of 9 months, who had previously been well, was admitted to the hospital with the history that three hours previously he had suddenly screamed, fell forward, and appeared lifeless. During the next twenty-four hours he had repeated attacks of unconsciousness which came without warning and lasted for several minutes. There were no convulsive movements and the bowels were always flaccid when examined. Between attacks the child was of normal color and showed very little evidence of shock. On the day following admission he passed a copious fluid stool containing much dark blood and mucus. No tumor could He recovered entirely and was discharged on the fifth day. The diagnosis in this case presented a problem until about a month later when the following case came under observation. A 16 months' old infant was admitted with a history of vomiting and attacks of unconsciousness almost identical with those in the first case. With the child under an anesthetic a tumor could be palpated under the costal margin. A laparotomy was performed and the appendix was found to be much injected. The enterocolic intussusception reduced itself under the surgeon's fingers. Further exploration revealed several enlarged mesenteric glands and four small intussusceptions, which were readily reduced. Recovery was uneventful. True attacks of syncope are exceedingly rare in infancy. These two cases are, therefore, of interest as exemplifying the rôle that intense pain may play in the causation of syncope in infancy. In the first case there was no vomiting and the intussusception seems to have reduced itself spontaneously. While it might be said that the diagnosis was not proven, the association of intense, spasmodic abdominal pain and the passage of a melena stool hardly admit of any other interpretation, except possibly that of recurrent volvulus.

Endoerine Associations.-In discussing the complexities of diagnostic problems that involve the interaction of the endocrine glands and their influence on metabolic levels and on the functions of the nervous system, Allan Winter Rowe says we must never fail to recognize that while established hasic principles are applicable to the predication of group behavior, the convenient artefact of the average cannot be too straightly applied to the individual component. Each member of the community is an entity, combining the subtle forces of heredity, of environment, both external and internal, and of nutrition, of growth, of development, and such others as may be regarded as intrinsic in the stuff of which we are compounded. As illustrating the association of endocrine influences with other conditions, without implication, postulating and causal-resultant Rowe cites a diagnostic study of individuals with otosclerosis, or better with progressive deafness. In such a group nearly 65 per cent gave objective evidence of endocrinopathy; the remainder were completely free from any suggestion of endocrine gland involvement, although all showed depar-tures from the normal. The endocrine group showed the pituitary at fault in 35 per cent, the thyroid in 11 per cent, the ovary in 14 per cent, while unclassified endocrine cases added 5 per cent to the total. In this group the restoration of a normal level of glandular function by the use of appropriate opotherapy has coincided with the arrest of the progress of the ear condition in a very appreciable number, while a significant fraetion has shown and maintained a demonstrable improvement. In a substantially consecutive scries of infertile couples, endocrine conditions were shown by 61 per cent, of which the pituitary was responsible for more than half (36 per cent), while the thyroid (15 per cent) and the ovary (9 per cent) follow in the order named. In these cases constitutional factors were always present. In the treated cases slightly more than 50 per cent yielded successful results. The correction of an associated cudocrine factor coincided, in a striking manner, with a correction of the basic condition in one-half of the patients treated. In the author's study of a group of children who presented behavior problems, 51 per cent showed pituitary dyscrasias, and 13 per cent were thyroid cases. In a consecutive series of psychotics and psychoneurotics, 76 per cent gave evidence of associated endocrine malfunction-41 per cent showed pituitary dysfunction, 12 per cent were thyroid dyscrasias, while 22 per cent were patients with ovarian failure. An adequate interpretation of these associations is impossible on the basis of the imperfect knowledge of today.-Endocrinology, September-October, 1933, xvii, 5.

Neurasthenia: Toxic and Traumatic.—H. V. Dick, writing in *The Lancet*, September 23, 1933, ccxxv. 5743, urges that it be more generally recog-

nized that "neurasthenia" is an obsolete term, expressing an obsolete theory completely obscuring the nature of the condition it is intended to describe, and is typical of the still prevalent lack of understanding of psychogenic illness or psychological theory. The neurological approach to psychopathology has had a paralyzing effect upon medicine in general, because so long as we followed it we remained outside the world of the patient's mind, moving on a plane which has no understanding of his personality as a whole. The term neurasthenia should be discarded, or used as an equivalent merely of "abnormal subjective fatigability without obvious organic cause." Dick cites two cases of so-called neurasthenia which illustrate the following generalizations: The symptoms of the so-called "neurasthenic state" a syndrome rather than a disease-are manifold, but reducible to the effects of long-continued unconscious fear or anxiety via the sympathetic system and its physiological connections, if, indeed, they have other than a subjective existence. Neurasthenic symptoms are, therefore, secondary to psychological conflict, and on the psychic side expressive of unconscious fcar, autoerotism, and the craving for protection and sympathy, in the service of the primitive urge to self-preservation.

Spontaneous Hyperventilation Tetany .-- J. W. Scott and M. M. Cantor state that the cause of tetany is generally accepted as an alkalosis resulting from the loss of carbon dioxide from the blood. With this depletion a preponderance of basic substances accumulates in the blood. These substances are excreted by the kidney and the urine becomes less acid. The authors report the case of a woman 21 years of age, a medical student, who was seen about an hour after she had first noticed that her wrists were getting numb and stiff. A diagnosis of spontaneous hyperventilation tetany was made. The patient was taken to the hospital and given a 5 per cent mixture of carbon doixide in oxygen. Within two or three minutes her hands began to relax, the respiratory rate, which had been 82 per minute, gradually slowed, and the spasm dimin-She was quite relaxed and comfortable eight minutes after the beginning of the administration of gas. She stated that four days before admission she had suffered from nausea and The latter readily responded to bismuth, but the nausea persisted, and she thought this might have been a factor in inducing deep breathing. Two days after admission, voluntary forced breathing produced tetany in three minutes, and at the end of ten minutes the blood showed a decrease in plasma bicarbonate, an increase in hydrogenion concentration with a slight rise in calcium and chlorides. The urine showed an increase in hydrogenion concentration and marked ketonuria. This case is of interest in that the spontaneous hyperventilation developed

in association with nausea, rapidly followed by the onset of tetany and the production of marked The rapid onset of tetany following increased breathing suggests that the patient may be peculiarly susceptible to carbon dioxide deficit. In considering the mechanism underlying this susceptibility to hyperventilation tetany, Essen has suggested that the bicarbonate deficiency is compensated for by an increase in the plasma chlorides. When this protective mechanism is impaired, as might be the case where the amount of blood chloride is less than usual, as where vomiting is a symptom, milder degrees of overbreathing may be quite sufficient to cause alkalosis and tetany. Experimentally it has been found that in the absence of organic nervous disease, signs of tetany rarely develop before ten to thirty minutes of forced breathing.—American Journal of the Medical Sciences, October, 1933, clxxxvi, 4.

Symptomatology of Aneurysms of the Innominate Artery.—On the basis of a case observed in a man of 35, F. Ferranti and G. Nizzinuti discuss the more important points in the symptomatology of aneurysms of the innominate artery. Frequently the first symptoms complained of are more or less acute pains, continuous or intermittent, in the right shoulder, radiating to the arm on the same side and often also to the right half of the cranium. In other cases the first signs consist of a sense of obstruction of the jugular vein, or attacks of dry, irritating coughing which does not yield to ordinary measures and which as a rule is regarded as an indication of bronchitis. The objective symptomatology will vary according to the location of the aneurysm: for example, if it is intrathoracic, it will affect the respiratory tract; if extrathoracic, that is, in the distal part of the artery, it will cause irritation of the right recurrent nerve or the brachial plexus. frequently the entire trunk of the innominate artery participates in the dilatation caused by the aneurysm, with its consequent symptomatology. Sometimes the onset is much more dramatic, and consists of symptoms not of compression but of cerebral anemia. In the later course of the affection, especially when it is intrathoracic, the patient suffers with increasing dyspnea, requiring him to remain almost immobile; respiration becomes stertorous and the dry cough may be accompanied by more or less extensive hemoptysis. The most frequent cause of death is rupture of the aneurysm into the trachea. The presence of a luetic infection is of importance for diagnosis. The most pathognomonic sign is the presence of a deeply pulsating swelling in the right supraclavicular fossa, simultaneously with stasis in the upper arm on the opposite side and in the left half of the face and head. The skin covering the swelling is sometimes normal, but often tense and characterized by the presence of dilated veins. If the aneurysm is exclusively intrathoracic, inspection may reveal a pulsation corresponding to the 1st and 2nd right intercostal spaces, with dulness on percussion; rarely is there a systolic murmur or a souffle, but heart tones are always heard as clearly as over the cardiac area itself. Other characteristic symptoms are injected conjunctivae, cyanotic lips, paralysis of the right vocal cord, and a difference between the radial and the carotid pulse, through retardation, slenderness or even complete absence of pulsations in the right Finally, the fluoroscopic and roentgenographic findings, taken together with the frequent finding of a positive Wassermann reaction, are decisive in diagnosis, in view of the frequency of a luetic history in such cases.—Riforma medica, August 19, 1933.

Paralysis of Upper Plexuses after Prophylactic Injection of Serum.—To the cases of Katz and Schilling of paralysis of the upper extremity after prophylactic injection of tetanus serum, H. Demme adds a third. Six days after the injection of the serum into the gluteal muscle for a lacerated wound of the thumb, a typical serum exanthem appeared with other characteristic signs of reaction. Three days later a very painful paralysis of the upper parts of both brachial plexuses set in, beginning with hypesthesia in the neighborhood of the nervi cutanei antibrachii laterales. After about 10 days came the actual plexus paralysis, which at first exhibited a progressive character, then came to a standstill, after which the acute symptoms abated, the pareses gradually regressing; months later, however, a weakness of the shoulder and upper arm musculature could still be observed, with atrophy and degeneration in the muscles chiefly affected. The question arose whether the bilateral shoulder and arm paralysis was attributable to the wound or to the serum injection. A study of the literature left no doubt that the injection must be held responsible, but that the antitoxin itself was not, as such, the injurious substance. It must, rather, be assumed that the paralysis was a kind of anaphylactic phenomenon, appearing as a reaction to the parenteral incorporation of the foreign body serum. This view receives support from the fact that a typical serum exanthem nearly always precedes the neuritic phenomena, as it did in this case. Clearly an anaphylactic edema may produce slow, lingering disturbances in nerve tissue much more easily than in the skin. It is also a striking circumstance that, independently of the site of the injury and of the infection, the paralysis in the great majority of cases affects the shoulder and arm musculature. In the present case the sensory disturbance was of a purely peripheral character, and even in the acute stage no meningismus was observed, so that it may be assumed that it was a case of brachial plexus paralysis. The prognosis in such paralysis is generally good, and in Demme's case most of the disturbances have already regressed. These cases of paralysis, however, constitute no contraindication to the use of tetanus or diphtheria serum.—Munchener medisinische Wocheuschrift, September 29, 1933.

Early Diagnosis, Clinical Course and Serum Therapy of Epidemie Poliomyelitis .- M. Gross and E. Glanzmann, writing in the Schweizerische medizinische Wochensherift of September 30, 1933, make a report on the basis of 23 cases of epidemie poliomyelitis which they treated during the epidemic of 1932. The course of the disease may be divided into the following stages: (1) An incubation stage of 6-18 days. (2) A stage of general infection of 1-3 days, characterized variously by fever, angina, eoughing or hoarseness, vomiting, headache or pain in the nape, constipation or diarrhea,-the clinical picture thus being not at all a characteristic one beyond the general infection of the upper respiratory tract, with intestinal symptoms, appendicitis-like pains, and frequently sweating. (3) A latent period of 1-6 days, in which the children often return to school. (4) The invasion of the nervous system, with a preparalytic stage of 1-6 days. (5) The paralytic stage, of indefinite duration. (6) Convalescence. In diagnosis, the so-ealled "spinal sign" in the preparalytic stage is of great value. The child is placed in a sitting position and asked to kiss his knee. If he is in the preparalytic stage he cannot do this, since it causes very severe pain along the entire back. Another very characteristic sign is the stiffness of the neck, which resists flexion in a forward direction; this was never absent in the authors' eases. The "Amoss sign" is also an aid in diagnosis: the child has an inclination, in a sitting position, to lean upon his two hands to hold his back upright, in hyperextension, like a severely rachitic child; if asked to cross his arms, he makes an effort to do so, but quickly resumes his former position. In about 10 per cent of cases a child goes to bed in good health, and awakens the next morning in a state of paralysis. Of the authors' 23 cases, 13 were treated with specific serum and 10 without. Almost the same results were observed in the two series of cases. It must, unfortunately, be admitted that in fulminant cases where the need is most urgent, serum fails. Thus in a seven-yearold boy whose history already placed him in this class, 20 c. c. antipoliomyelitis serum given intralumbally and 20 c. c. intramuscularly on the second day of the disease proved useless and the child died on the third day with paralysis of the diaphragm. On the other hand a case that is almost decisive for the good results of serum therapy was that of a three-year-old child in whom double pneumonia developed on the tweIfth day of the poliomyelitis, and who nevertheless pulled through and made a perfect recovery from paralysis, in the face of what semed desperate conditions. In nine other serum cases the paralysis was overeome in greater or less degree. Of those not treated with serum, three died, three were completely cured, and two were considerably improved. The cases so treated were as a rule the ones with the most severe infection.

Anaphylaetie Manifestations from Insulin .--According to Salvatore Fiandaca, some of the first observers of anaphylactic shock during the course of an insulin treatment believed the phenomena to be due to protein impurities in the insulin. But when this view was refuted by the appearance of the same symptoms after use of an aqueous solution of erystalized insulin, demonstrably free from protein, the suspicion arose that insulin might, of itself, constitute a specific antigen, capable of sensitizing the organism. Fiandaca, after treating over 400 patients with insulin, has recently had a unique case that confirms this idea. woman of 52, who had been receiving 20 units of insulin per day for about 10 days without any special incident, felt so much better that she gave up the treatment and was not seen again for about 8 months. She then returned with all her old diabetic symptomatology, and in addition a troublesome pruritus vulvac, for which no gynecological grounds could be discovered. About 30 minutes after her first injection of 10 units of insulin, she had a profound sense of illness, with tachycardia, vertigo, and dyspnea. The same symptoms followed the second and third injections, very intense after the third, when there also appeared simultaneously a number of large, elevated, erythematous spots in the right supramammary region, but none at the site of injection. This phenomenon lasted about three days, despite suspension of treatment. Blood examination confirmed the existence of a hemoclastie shock. Two more injections of 10 units each, given on the fourth and sixth days after this crisis, with a view to proving the etiology of the eruption, were followed by further anaphylactic manifestations, the eruption now covering the entire body except the palmar and plantar regions; on the last occasion a different brand of insulin was used, with the same results. No disturbance, however, followed an injection of extract of suprarenal cortex. Twelve healthy subjects were then injected intradermally with the patient's serum, followed 24 hours later by a few drops of antigen (insulin), three different preparations being used. In every case a painful, pruriginous wheal 1 cm. in diameter appeared at the site of injection, 30 minutes later. On the other hand, administration of pancreatin per os gave a negative result, proving that the sensibilization was not due to the presence of panereatic proteins.-Riforma medica, September 23, 1933.

LEGAL

PERSONAL INJURY ACTION-LIABILITY OF GOLF PLAYER

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

A large number of physicians are devoted followers of the royal and ancient game of golf. A recent case for personal injuries, involving the liability of both player and golf club, was the subject of decision by one of the judges of our lower courts in this State.

In the case under consideration the plaintiff, a young woman, was being driven by a friend of hers in an automobile. The car was going east upon Union Turnpike in Jamaica. The defendant golf club was located to the right of the car in the direction in which it was proceding. Union Turnpike runs east to west, and the southerly edge of the course abuts the Turnpike and is lined by a wire fence about six feet high, located about twenty-five feet south of the roadway. The first hole of the course adjoins the Turnpike, and the tee of the first hole is so situated, in relation to the green, that one driving from it will drive a ball in a westerly direction, almost parallel to the highway.

The defendant golf player was playing with three other club members. He teed off, and the ball traveled westerly about two hundred yards, fell short of the hole, but remained upon the fairway. His next stroke carried the ball to the right over the fence, on to the roadway and struck the windshield of the car in which the plaintiff was traveling, shattering it and causing injuries to her. Subsequently she commenced this action to recover damages against both the player and the golf club, on the theory of negligence and nuisance.

On the trial the defendant player disclaimed negligence on two theories: First, that he struck the ball intending and believing that it would travel along the proper path, and therefore, he should not be held liable for a mere error of judg-Secondly, that the ball was caught in a tail or cross wind, or some other atmospheric condition which he could not foresee, which rendered the occurrence an "act of God." The player submitted that he did everything that a reasonably prudent man would have done under the circumstances; that he exercised due care in playing the ball, that he looked around, shouted "fore," and then struck the ball, intending it to travel in the proper direction; and that the fact that the ball veered to the right and struck the car could not have been reasonably anticipated.

The defendant golf club maintained on the trial that no negligence could be imputed to it, for the

reason that there was nothing in the evidence tending to show anw breach of duty on its part; that there was no proof that any balls had been previously hit over the fence or that the club had any notice of such previous occurrence; that the club could not be required to anticipate danger from the source in question, and that therefore it could not be guilty of negligence in failing to guard against such happening.

The action was tried by the court without a jury, and the facts were not substantially disputed. As the court said:

"I am satisfied from the evidence that the ball was 'sliced' by X; that is, he hit it with a cut across it, so that it flew with a curve to the right. It is a matter of common knowledge that such a thing will happen to the most experienced player. That he intended to drive the ball correctly is unquestioned, but his liability or freedom therefrom can only be determined in terms of law."

The court then pointed out the paucity of legal precedent involving the facts in the case at bar, stating that only one case had been found in point, and that was decided in England, in which case the driver of a cab in proximity to a golf course was permitted to recover. The English case was decided on the theory that the player was negligent in striking the ball while there was someone upon the adjoining roadway who might be injured by a misdirected ball, and that the golf club was also liable on the theory that the particular portion of the grounds was a public nuisance under the conditions and in the place where it was situated. The English court held that the club was under a duty to obviate the danger to persons upon the highway, and that this could be done in several ways, as by having a lesser number of holes, or omitting the objectionable hole, or playing it in a different way.

In the instant case the court paid a high tribute to the game of golf in this language:

"The ancient game of golf had its origin in Scotland. It was formerly indulged in by only kings and the nobility. It furnishes a healthy means of exercise and relaxation, and is a sport of the first order. In more modern times the game spread to England, and its popularity has so increased that the game is now extensively in vogue in this and other countries among all classes of people.

"A golf ball in i self is an innocent, lawful article, and so is the club which drives it. The game itself, being fundamentally honorable and sportsmanlike, suggests nothing imminently unlawful or hazardous about it."

The court then went on to apply established legal principles to the facts in the case, and said:

"But when driven, though in full compliance with the rules of the game, the ball attains great speed, and may thus become a dangcrous and destructive object, and may strike with great violence and lorce, not unlike a projectile which is propelled from a weapon by whatever power it be actuated, or a stone thrown by a catapult or by the hand. In a recent case, Judge H, himself an accomplished player, in holding a golf player liable for the injury of a caddy by a ball, writing for a unanimous court, says: "It must be conceded that although golf may not be deemed a hazardous game, a driven golf ball is a very dangerous missile, and that its flight and direction cannot always be controlled by the player. That uncertainty is a part of the game. The ball when struck is liable to go on down the fairway or fly off to the right or left at almost any angle."

angle."
"The element of danger, therefore, though not intrinsie
in the game itself, is nevertheless present, according to
a given set of circumstances. The situation is not changed
by the fact that the act of propelling the ball is in itself
not wrongful and is for a lawful purpose, that is, to play

the game.

"The presence of the risk imports liability. As was stated by Judge Cardozo in one case: 'The risk reasonably to be perceived defines the duty to be obeyed, and risk imports relation; it is risk to another or to others within the range of apprehension (citing authorities). This does not mean, of course, that one who launches a destructive force is always relieved of liability if the force, though known to be destructive, pursues an unexpected path. "It was not necessary that the defendant should have had notice of the particular method in which an accident would occur it the possibility of an accident was clear to the ordinarily prudent eye" (citing authorities)."

"If there be a possibility of danger, and if the doing

"It there be a possibility of danger, and it the doing of a lawful act may naturally and probably result in harm, though unintended, in relation to plaintiff, there is an actionable wrong (citing cases). The plaintiff here had a right of bodily security, and she was entitled to be protected against being struck by the ball, and if that right has hen violated slie may recover, although, as just stated, the interference with her right did not result from the knowing and willful conduct of delendants, so long as the striking of the ball and the causing of harm to her

was within the range of natural probability.

"Like baseball, the golf game is not a nuisance per se. Both games involve the same element, i.e., striking the ball with an instrument with lorce so as to send it spinning into the air. If, however, the ball playing is attended with a reasonable degree of danger as to make it likely that it would 'work hurt' upon the traveler in the street, a question of fact is presented, and if it be decided adversely to the parties who are responsible for, or who participated in, or who authorized, the setting of the ball in motion, liability will attach on the theory that the playing was a muisance (citing cases). In the first two cases (cited) the plaintiff was struck by a ball batted upon premises adjoining the highway while plaintiff was upon it; and in the third case plaintiff was upon private premises abouting the playground. In all of said cases the doctrine was applied

"This plaintiff had a right to be traveling in the automobile upon the highway. The ball hit the windshield suddenly. She could not be expected to watch out for deflected golf balls in the path of the car, and, even if she were, there is nothing to indicate that she could have reasonably done anything to avert the accident. For aught that appears, she did not know that the golf course was there or that a golf game was in progress at the time. The roadway itself was safe, the car was being carefully driven, and the conditions were such that no one on the highway—certainly not a person sitting in a passing carcould be reasonably required to anticipate that a ball might fly against the car any moment. Plaintiff was in substance and effect in the same position as any other traveler or pedestrian who, without warning, is struck

by an object falling from a structure. In one case it is said: 'The primary purpose of highways is use by the public for travel and transportation, and the general rule is that anyone who interferes with such use commits a nuisance.'

"The rights of the public to a free and unmolested use of the highway are paramount (citing cases)."

In rendering the verdict in favor of the plaintiff and against both player and golf club, thus following the ruling in the English case to which reference has already been made, the court said:

"Applying the principles enunciated by the above authorities, no reasonable distinction can be apprehended between the case of a traveler upon a public street being struck by a falling building or falling into an excavation adjoining the roadway upon private property, or being injured by a missil set in motion from private adjacent premises. And, if the owner of land contiguous to the highway is liable to a traveler who falls into an excavation on the land, upon the ground that the owner has not provided a means whereby harm might be reasonably averted to one having no cause to expect danger, then, by analogous reasoning, the converse situation must also determine liability—that the owner of such premises who creates a condition upon his land, or who maintains such a condition in a manner imputing presumptive knowledge thereof, whereby an ohject from the land injures a lawful traveler upon the roadway, is in duty bound to take appropriate means to ward off the danger.

"Whether this may be done by any method, or by a given means, is forcign to the issue. It is regrettable that this accident has happened, and that the defendants must be held liable in terms of law. Even if such an accident had never happened before, that fact would not be enough-to avert liability. Only if such an accident were unlikely in the highest degree, in the minds of reasonable men, would there be basis for exoneration (citing cases). In the development of civilization and social relations, the law has been moulded to meet ever-changing conditions, and has been adapted to them without revolutionary effect, but on the contrary, with beneficial results to society at large. Witness the application and expansion of established rules of law to hitherto virgin domains, such as radio and aviation. So must i' be with accidents and a variety of other circumstances which are bound to arise in their own appointed time. As was said in one case, in which a boy was struck on the head by an abandoned insulator containing a projecting screw which caused severe injuries. 'This occurrence of the accident in question was of such an extraordinary character that perhaps the defendant might not be chargeable with the duty to anticipate just such a completed happening as this, but the precise character of the accident is not a matter of controlling importance, for so many strange things happen in life that if we were in be exonerated from liability for our acts because of the novelty of the result, the measure of liability would be very largely restricted. What was strange was not that the insulator should fall, but that it What was should fall in such manner as to strike with the screw."

"So, here. The rare thing was that the ball, although played by an experienced sportsman, should veer off, go over a 6-foot fence, and strike the car on the turnpike. That, and the proximity of the course and its particular lole to the highway, are the two proximate, concurring causes of the accident, and cach is an efficient cause. Resipsa loquivir. The player's liability rests in negligence for failure to use the degree of care required in the particular circumstance, he being accountable for the natural and probable consequences of his act in propelling the ball, and the club is answerable for creating and permitting the condition to exist, as well as for failure to use reasonable care to prevent injury to a person lawfully upon the highway, such as the plaintiff. .The accident could not have happened without the concurrence and co-

operation of both causes. Under such circumstances, both are jointly and severally liable, even if the liability of each is grounded upon an independent theory (citing case), and plaintiff is not required to elect whether to proceed on the theory of nuisance or negligence as against each; a recovery on one or both theories being permissible (citing cases). It is not likely that the conclusion I have

reached will work undue hardship upon any golf club,

since the risk may be readily insured against for a premi-

um which in the nature of things will be quite small.'

As many of our golf courses have holes border-

ing on the public highway, and it is an established fact that many of us are prone at times to wild hooking and slicing, it will be interesting to follow the progress of this case in the event of an appeal. While, of course, sympathy for the injured person makes it difficult to quarel with the decision rendered, the incident which forms the subject-matter of this case seems to be one of those accidents for which neither golf player nor golf club is really responsible.

CLAIMED NEGLIGENT DIAGNOSIS AND TREATMENT OF RIGHT LEG AND SHOULDER

A general practitioner received a phone call to come to the home of a man who was injured. Upon arrival he found the patient was a man about thirty-nine years of age, conscious and sitting in a chair. He gave a history of having been on a ladder about two stories high; the ladder tipping and he falling to the ground, striking his right elbow, right side and right foot. He complained of pain in his elbow and lameness in his side. There was no history of unconsciousness and no other complaints were made. Examination ·disclosed the right elbow badly swollen all around, discolored, bruised and motion greatly limited. The doctor immediately advised an x-ray and communicated with an x-ray specialist and arranged an appointment immediately. His arm was put in a sling and the patient taken to the office of the x-ray specialist. X-rays were taken, which were fracture. The ligaments negative as to around the elbow were markedly and extensively lacerated. The patient was informed that there would probably be a very slow recovery and there was some possibility of permanent damage to the elbow. The x-ray doctor who specialized in surgery concurred in this diagnosis. There were no other complaints made at any time and on manipulation the shoulder was apparently normal. Dressing was applied to the elbow and the arm left in a sling. The patient went home and on the following day the doctor again visited him. At this time the patient complained of pain in the foot. Examination revealed the right foot badly swollen but no evidence of any fracture. No x-ray was taken of the foot. Examination of the arm showed it to be tender, ecchymotic, very much swollen, hematoma on the outer side below the elbow. The arm was lame and all motions of the elbow were very limited. The doctor saw him daily after that, the swelling of the arm was still present and motion had not improved at the elbow. The patient called at the doctor's office daily to receive

infra red and diathermy treatments to the elbow and at various times his foot was strapped. Gradually the swelling in the elbow subsided, the discoloration disappeared but the motion did not improve. The foot in the meantime improved and required little attention. After about a month another x-ray showed no evidence of fracture. The doctors in consultation decided that the elbow was bound down by adhesions and under an anesthesia a forced manipulation was done to break up these adhesions. Thereafter the diathermy and infra red treatments were continued. After treating this patient for about six weeks, one day the patient did not appear. The patient called the doctor and made another appointment and again disappointed the doctor. This was done several times and finally the doctor called at the patient's home to find out how he was getting along. The patient stated that he had been advised by someone to go to a chiropractor: that he had consulted a chiropractor and had been advised by him to go to a physician. He refused to disclose the name of the physician but stated that this physician had advised him that his elbow was shattered and that an x-ray of his shoulder showed a fracture. The doctor upon hearing this asked the patient to permit him to take an additional x-ray of his arm and shoulder, which was refused by the patient. The patient stated that he did not wish to be treated any further.

About two months later the doctor was sued for malpractice. The claim was negligent diagnosis and treatment of the right arm and negligent diagnosis of the condition of the broken shoulder. The answer of the doctor denied all allegations of negligence.

The case came on for trial before a Judge and Jury and at the close of the plaintiff's case a motion was made to dismiss the complaint upon the ground that the plaintiff had not proved a cause of action set forth therein; and said motion was granted, thus terminating the matter in favor of the defendant,

NEWS NOTES

THE SECOND DISTRICT BRANCH

The Twenty-seventh Annual Meeting of the Second District Branch of the Medical Society of the State of New York was held in the afternoon and evening of Thursday, November 16, 1933, in the Garden City Hotel, Nassau County, with an attendance of well over 200. The District comprises the four counties of Kings, Queens, Nassan and Suffolk, which includes the whole area of Long Island. Every phase of the program had a distinct objective for the good of the Branch. The afternoon was devoted to three events:

A bridge party,
 An airplane ride.

3. A scientifie program.

The bridge party was designed for the instruction as well as the entertainment of the ladies, and was under the direction of Mrs. Janet A. Krantz, an expert teacher of contract bridge.

Garden City is near a great aviation center and free airplane trips were provided by Mr. Harry F. Wanvig, for the pleasure of the doctors and their wives. About forty guests took the ride covering a part of New York City.

The scientific session was on the subject of "The Acute Abdomen," with an all-Long Island program. Practical talks were given from the standpoint of the:

Surgeon: John E. Jennings, Brooklyn; and J. Wesley Bulmer, Glen Cove.

Internist: Carl Boettiger, Flushing; and Irv-

ing Gray, Brooklyn.

Gynceologist: Charles A. Gordon, Brooklyn.

Urologist: James W. McChesney, Baldwin. Neurologist: Orman C. Perkins, Brooklyn. Pediatrician: Miner C. Hill, Oyster Bay.

The talks were discussed by doctors from the four counties on Long Island, Doctors John M. Scannell, Queens; Charles C. Murphy, Suffolk; Joseph S. Thomas, Queens; Louis H. Bauer, Nassau; John B. Healy, Suffolk; Francis G. Riley, Queens; Augustus Harris, Kings; Irving J. Sands, Kings; Charles W. Martin, Queens; Louis A. Van Kleeck, Nassau, and Lewis A. Koch, Kings.

Ninety doctors were present and showed their interest by remaining throughout the session.

The evening session began with a banquet with an attendance of 183, including the wives of the doctors. The President, Dr. Louis A. Van Kleeck, presided, and many of the more active doctors, guests, and ladies enjoyed dancing between the courses and after the dinner.

Dr. Alee N. Thomson, secretary of the Branch,

gave a report of the peculiar activities of the These activities had been conducted under the initiative and direction of an Executive Committee composed of the officers of the Branch and delegates of each county society. The committee had held regular meetings and outlined plans which were to be followed by the constituent societies as well as the Branch. Its major project was the development of a plan to coordinate all of the agencies engaged in public health work on Long Island. This plan has been approved by the four county societies of the Branch, and will be put in operation as soon as the means for doing so can be secured. Long Island is peculiarly well situated for the demonstration, for it contains 1,000 square miles, and 4,000 doctors, and a population of 4,000,000 who live under conditions varying from the congested urban area of Brooklyn, and shading away to the strictly rural sections of the eastern end of the Island. The Executive Committee was authorized to devise means for raising funds to conduct the demonstration.

A revised constitution was adopted giving formal authorization to the formation of the executive committee, thereby enabling the Branch to function actively throughout the year.

Secretary Thomson also reported on the work of the Women's Auxiliary which had been formed by the Queens County Medical Society—the first auxiliary in New York State.

Dr. Frederick H. Flaherty, President of the Medical Society of the State of New York, brought the greetings of the parent society, and complimented the Branch for its varied activities and the unique work done by the executive committee in making the Branch an active entity.

Dr. Samuel Kopetzky, Speaker of the House of Delegates of the State Society, spoke on the opportunity for the physicans to control their own destinies after years of being controlled by their environment. He urged the county societies to choose nen of vision and leadership as their representatives to the House of Delegates.

Dr. Frederick E. Sondern explained the group plan of insurance against malpractice that has been adopted by the State Society, giving facts and statistics that are not generally known among physicians. He demonstrated that a young physician cannot afford to neglect to protect himself by taking out a malpractice insurance policy, since the most skilled doctors are as susceptible to law suits as are their less prominent brethren.

Dr. Sondern also reminded the doctors that they

should take out liability insurance against ordinary accidents to which their patients are liable in their offices, such as slipping on floors and falling down

Dr. Harry Aranow, chairman of the Committee on Legislation, spoke of the importance of the legislative work in protecting physicians in their practice. But still more important is the protection of the public. The newer method of promoting effective legislation is to get the people themselves to influence their legislators in the interest of scientific medicine.

Mrs. H. Roy Van Ness, Organization Chairman, Eastern District of the Woman's Auxiliary of the American Medical Association, gave an address on the reason for the Woman's Auxiliary. She emphasized the opportunity of the doctors' wives to promote public health and to influence the public to support the movements by which medical services are given. She particularly urged that all the county societies of the Island form auxiliaries, following the example of Queens. Dr. W. W. Bauer, Director of the Bureau of

Public Health and Instruction of the American

Medical Association, read a paper on "The Health of the School Child." The doctor outlined the principles which he believed to be fundamental in the maintenance of the health of school children. He started out by saying that a basic principle of health work among school children is to return them to their homes in as healthy a state as they were when they came. This principle includes sanitation, protection against communicable diseases, and guarding against bad health habits.

Doctor Bauer also went into the subject of the physical examination of the children by private practitioners, and their relations to the school authorities in the correction of defects. He emphasized the great importance of influencing the parents in this regard, and clearly differentiated the duties of school medical advisers, and the responsibility of the family physician. The Bureau of Public Health and instruction of the A. M. A. has studied the subject under all the varied conditions that prevail throughout the United States, and Dr. Bauer therefore speaks with authority regarding measures for promoting the health of school children.

GRADUATE EDUCATION COURSES

The Committee on Public Health and Medical Education announces that a course on Heart Disease for the Madison County Medical Society has been arranged by Dr. John Wyckoff, New York City, in the Oneida Hotel, Oneida, N. Y. The program is as follows:

November 9, 1933—

Cardiac Structure and Its Disorders, Dr. Clarence E. de La Chapelle, 140 East 54th Street, New York City.

November 16, 1933—

Cardiac Functions and Their Disorders, Dr. A. C. DeGraff, 75 East 55th Street, New York City.

November 23, 1933—

Rheumatic Fever and Rheumatic Heart Disease, Dr. Currier McEwen, 477 First Avenue, New York City.

December 7, 1933—

Hypertension and Hypertensive Heart Disease, Dr. William Goldring, 470 Park Avenue, New York City.

December 14, 1933—

Syphilitic and Arterio-sclerotic Heart Disease, Dr. John Wyckoff, 75 East 55th Street, New York City.

The Committee also arranged an afternoon of medical and surgical clinics for Wednesday, November 22, in the Ithaca Memorial Hospital, under the joint auspices of the medical societies of Cortland and Tompkins Counties. Dr. Russell L. Cecil and Dr. Russell H. Patterson, both of New York City, will conduct the clinics. These clinicians will also give lectures at an evening session.

The following course on Physical Therapy has just been arranged for the Bronx County Medical Society by the Committee on Public Health and Medical Education of the Medical Society of the State of New York:

External Heat Measures, Including Hydrotherapy—Dr. Heinrich F. Wolf.

Medical Diathermy—Dr. Richard Kovacs. Surgical Diathermy—Dr. William Bierman. Massage and Exercise—Dr. Heinrich F. Wolf. Low Frequency Currents and Electrodiagnosis -Dr. Richard Kovacs.

Ultraviolet Radiations—Dr. Richard Kovacs. Place: Fordham Hospital, Bronx, New York. Time: Monday and Friday, 4 P.M., begin-

ning January 8, 1934.

It is planned to furnish a short synopsis of each lecture which will be distributed to those attending the lecture, before the date of the lec-

THOMAS P. FARMER, Chairman.

FRANKLIN COUNTY

The regular annual meeting of the Medical Society of the County of Franklin was held in the Nurses' lecture room of the Alice Hyde Memorial Hospital, Malone, N. Y., October 30, 1933, with the President, Dr. J. W. Kissam, in the chair, and 19 members present.

The following officers were elected for the

year 1934:

President, Dr. G. C. de Grandpre, Tupper

Vice-President, Dr. R. G. Perkins, Malone.

Secretary-Treasurer, Dr. G. F. Zimmerman, Malone.

Censor for three years, Dr. W. W. Woodruff,

Saranac Lake.

Delegate to State Medical Society, Dr. C. C. Trembley, Saranac Lake.

Alternate, Dr. J. E. White, Malone.

Drs. Reta E. H. Morse, and Dr. Carter R. Morse, both of Tupper Lake, were received into membership by transfer from the St. Lawrence County Medical Society.

Dr. Perkins reported a conference which he

held with the Presidents of the counties composing the Fourth District Branch, with a view to securing uniform action in the matter of fee

An Auditing Committee was appointed to meet once in three months with the County Welfare Commissioner to audit and adjust any bills for county work that may be in dispute.

The following papers were read during the

scientific session:

"Abscess of Brain-Diagnosis, Pathology and Treatment," Dr. W. V. Cone, Assistant Professor of Neurological Surgery, McGill University.

"The Prostate-Its Pathological Aspects and Newer Forms of Treatment," Dr. David W. McKenzie, Clinical Professor of Urology, Mc-Gill University.

"Psychoneurosis," Dr. Harold W. Berman, Acting Director of Clinical Psychiatry, Lawrence State Hospital, Ogdensburg, N. Y.

The papers were of special value to general practitioners and were enlivened by clinical re-

G. F. ZIMMERMAN, Secretary

BRONX COUNTY

The first Stated meeting of the Bronx County Medical Society under the administration of Dr. M. O. Magid, was held on October 18, 1933, at 8:45 P.M. An unusually large audience attended the meeting which was held at the Concourse Plaza Hotel.

The President's inaugural address, followed by timely and pertinent remarks of Drs. T. Townsend, David Kaliski and J. Masterson, was universally approved by the audience, especially the nine-point plan suggested in the course of the talk.

Among other constructive measures advo-

cated by the Society were the following: A motion was made, seconded and carried that a letter of protest be sent to Dr. Shirley Wynne, Dr. R. S. Copeland in connection with their radio broadcasting; and also that letters of a similar nature be sent to each of the five

county societies, urging them to send letters of protest to these doctors.

The following resolution was adopted by the Society:

"Whereas, The ambulance surgeons who answer emergency calls to the bedside, are expected to perform services which the medical profession thinks they are not qualified to per-

"Resolved, That the Bronx County Medical Society recommend to the proper authorities, the Mayor, the Health Commissioner, and the Commissioner of Hospitals, that the post of ambulance surgeon be a civil service position to be filled by one who has had a hospital training and that the young interne merely assist this ambulance surgeon on his calls."

I. J. LANDSMAN, Secretary.

GENESEE COUNTY

The annual meeting of the Genesee County Medical Society was held in East Pembroke on November 2, 1933, with the Vice-President, Dr. R. B. Smallman presiding, and seventeen members present.

The following officers were elected for the year 1934:

President, Ralph B. Smallman, Corfu. Vice-President, C. D. Graney, Le Roy. Secretary and Treasurer, P. J. Di Natale. Delegate to the State Society, P. J. Di Natale. Chairmen of Committees were announced as

follows: Economics, S. R. Hare; Public Relations, G. H. Knoll; Public Health, H. M. Spofford; Legislative, P. J. Di Natale; Physio Therapy, I. M. Steele; Membership, I. A. Cole; Program, P. J. Di Natale.

Dr. Earl D. Osborne, of Buffalo, gave an illustrated talk on "Some Common Skin Diseases." P. J. DI NATALE, Secretary.

DUTCHESS-PUTNAM COUNTY SOCIETY

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday, November 8, 1933, at 8:45 P.M., at the Chimney Corner, 29 Market Street, Poughkeepsie, N. Y., with the President, Dr. S. E. Appel, in the chair and 42 members present.

Dr. Alice D. Watts, Poughkeepsie, N. Y., and Dr. Morris J. Frank, Beacon, N. Y., were elected to membership.

An invitation from the Columbia Medical Society to attend the graduate course of lectures at the Hudson City Hospital was read.

The President appointed Drs. Deyo, Krieger and Meyer as a nominating committee.

SCIENTIFIC PROGRAM

Dr. Louis C. Kress, Assistant Director, New York State Division of Cancer Control, gave a paper on "Five Year Cancer Cures," illustrated with lantern slides. The paper was discussed by Drs. Davison, Harrington, Breed, Thomson, Baldwin, and Krieger.

The meeting adjourned at 10:30 P.M. for refreshments. H. P. CARPENTER, Secretary.

JEFFERSON COUNTY

The annual meeting of the Medical Society of Jefferson County was held at Watertown, on November 9, 1933. with Dr. Walter S. Atkinson, President, in the chair.

The following officers were elected for the

year:

President, Dr. E. E. Babcock of Adams Center.

Vice President, Dr. David G. Gregor of Watertown.

Secretary, Dr. Charles A. Prudhon of Watertown.

Treasurer, Dr. Walter F. Smith of Water-

Censors, Drs. W. S. Atkinson, H. G. Farmer, S. C. Hollis, H. L. Gokey and G. E. Sylvester.

The scientific program consisted of a symposium on neurology by doctors from Syracuse University Medical College:

Anatomy, by Dr. Eugene Boudreau. Pathology, by Dr. Wardner D. Ayer. Clinical Manifestations, by Dr. Albert Siewers.

Dr. A. M. Judd of Adams Center discussed an obstetrical film shown at the October meet-

ing in a short talk entitled "The Challenge of the Last Reel."

The work of the Tumor Conference during the past year, of the plans for the coming year were described by Dr. J. R. Pawling.

The following resolution was offered by Dr. Norman L. Hawkins and passed by the society:

"Whereas, there is an agitation to change the code in relation to the grade of milk, and

"Whereas, we feel that there are producers who are producing a natural or raw milk of the highest grade and safest quality, and

"Whereas, there is sold some pasteurized milk which we feel does not safeguard the consumer,

"Therefore, be it resolved that we favor and recommend the continuation of the sale of natural milk from cattle which are tested for tuberculosis, and blood-tested for B. abortus, and produced in a cleanly way; and that this resolution be sent to other county societies through the State Journal."

C. A. PRUDHON, Secretary.

DR. JOHN H. JEWETT

Dr. John H. Jewett, who had practiced medicine in Canandaigua, Ontario County, for fifty-four years, died on October 14, 1933, aged 79 years. He was the son of Dr. Harvey Jewett who was president of the Medical Society of the State of New York in 1883; and he leaves a son, Dr. C. Harvey Jewett, who is now prac-

ticing in his home town. A line of three generations of physicians in a family is worthy of note. An address by Dr. J. N. Vander Veer in appreciation of Dr. J. H. Jewett's half century membership in the Ontario County Medical Society appeared in this Journal of November 15, 1929, page 1394.

BOOK REVIEWS

NEUROPATHOLOGY. The Anatomical Foundation of Nervous Discases. By WALTER FRIEMAN, M.D. Octavo of 349 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$4.00

Up to the present time the subject of Neuropathology has been conducted by lectures in the majority of Medical Schools. It has been the desire of every teacher of this subject to have a text for this course as it has been separated from the general course of Pathology. We not only find an excellent piece of bookmaking but also an author well recognized in his field of work Dr. Freeman has covered the entire subject in a simple but complete manner. We would certainly recommend this book to every practitioner of medicine as il deals with the most up-to-date interpretations of pathology of the central nervous system.

O. C. Ferkins.

Obstetrics and Gynecology. Edited by Arthur H. Curtis, M.D. Volume 1. Octavo of 1165 pages, illustrated. Philadelphia, W. B. Saunders & Company, 1933. (To be published in three volumes and a separate desk index.) Cloth, \$35 00 for the set.

Onstetrics and Gynrcology, Vol. 2, Pathology of Labor and of the Puerperium, Operative Obstetries, Infectious Processes and Tumors, Edited by Arrilla H. Curtis, M.D. (Published in three volumes and a separate desk index.) Octavo of 1135 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$35.00 for the set.

These volumes are presented by the heads of departments and other prominent teachers in the leading medical schools of America. The authors were chosen from a complete list of specialists in Obstetries and Gymecology, and eminent teachers in allied fields. Dr. Curtis says: "It is planned to publish a new edition every five to eight years, the work of former authors being reedited by them, or by some worthy successor. A new editor is to be chosen from time to time to carry on the work."

The books will become an encyclopedia of obstetrics and gynecology, and will have a place, not only in the library of every progressive practitioner in this specialty, but also in every reference library of medicine.

library of every progressive practitioner in this specialty, but also in every reference library of medicine.

These volumes will be of interest and great profit to every obstetrician and gynecolgist, a model for teachers, and a wonderful textbook for advanced students. All of the many subjects presented are of interest, and a few of the chapters are all absorbing. For instance, the Historical Chapter in the beginning of volume I, and the chapters on Pubert, and The Menopause.

In volume II, one's attention is immediately focused on the chapter on the History of American Gynecology, and the entire section on Infectious Processes.

It is impossible in a short review to do justice to this nonumental work, but the great value of these books is at once apparent when it is realized that each chapter has been written by an author who is an outstanding authority on that particular subject. W. S. Suith

A LABORATORY MANUAL OF NEURO-ANATOMY. By C. L. DAVIS, M.D., and H. S. RUBINSTEIN, M.D. Part 2, Stereographic Plates. Octavo. 30 plates. Baltimore, William Wood & Company, 1933. \$300.

This manual comprises a series of stereograms, originally made for the purpose of teaching neuro-anatomy to medical students. It is designed for the purpose of replacing actual specimens of brain sections

whenever they are not available for the student. The collection of charts of photographs and drawings are neell selected, and well put inp technically, and they afford a really valuable adjuvant in the study of neuro-anatomy not only to students but to physicians as well. To the teacher of neuro-anatomy, the manual should prove of inestimable value in brushing up on various topics before meeting the class. The manual should fill a want in medical literature.

IRVING J. SANDS.

THE BIOCHEMISTRY OF MEDICINE. By A. T. CAMERON, M. A. & C. R. GILMOUR, M.D. Octavo of 506 pages. Baltimore, William Wood & Company, 1933. Cloth \$7.25.

The authors attempt to lead us into the inner complexities of Biological Chemistry. The reviewer intost impressed by their assiduous use of guide lines throughout the work, such as their labeling the radical components of organic compounds. The material is well chosen, and thought inducing. The book is replete with clinical, chemical and laboratory information; yet, there is no attempt at padding. This reviewer found the volume of a nature to be "read," not alone consulted as a manual, written in a style both appealing and instructive, and a valuable addition to any clinical library.

Samuel Duborr.

URINE AND URINALYSIS By LOUIS GERSHENFELD, Ph.M. 12mo. of 272 pages, illustrated. Philadelphia, Lea & Febiger, 1933. Cloth, \$2.75.

This volume is an up-to-date monograph on urinalysis. The author has had a very extensive practical and teaching experience in the subject. The urine is considered from all its aspects. The laboratory methods of examination, the nature of cases in which abnormal findings prevail and the aid that may be reasonably expected to be forthcoming from such examinations are suggested. The data are presented concisely, There is a brief historical review describing the examination of the urine from the earliest to the present era. There are chapters describing the structure and functions of the kidneys, the physical and chemical characteristics of the urine, and abnormal constituents. Then the various qualitative and quantitative tests are described, The most frequently used kidney function tests are given as well as tests for the detection of metallic poisons in the urine. There is also a description of the urine pregnancy tests. In the appendix are brief descriptions of colorimetry, nephelometry, scopometry, and spectroscopy as used occasionally in urinalysis. The common reagents used in urinalysis are also given in the appendix.

THE SCIENCE OF HUMAN REPRODUCTION. Biological Aspects of Sex. By H. M.:Parshley, Sc.D. Octavo of 319 pages, illustrated New York, W. W. Norton & Company, Inc., [c. 1933]. Cloth, \$350

This book presents in simple but adequate fashion the important data concerning the anatomy and physical control of the interesting subject the first the no the interesting subject the state of the st

phenomena of with the

÷

1

chromosomes and sex determination are presented. The anatomy of the normal reproductive organs, the changes produced during pregnancy, the life of the embryo, and the role the various endocrine glands play in reproduction and in the sexual and physical development of the female are all dscussed and elaborated upon. The concluding chapter is taken up with a rather philosophic dissertation on the biology of sex behavior, including such subjects as the biologic urge, monogamy, eelibaey and sublimation.

David I. Abramson.

A Companion to Manuals of Practical Anatomy. By E. B. Jamieson, M.D. Third Edition. 16 mo. of 654 pages. New York, Oxford University Press, 1932. Cloth, \$5.00.

This is a 3rd edition of a manual that first appeared about 20 years ago. This work is a small and compact volume and although the type is fine in the descriptive parts, it is nevertheless clear, concise and readable. The B. N. A. classification is used throughout—except the joints which have the revised classification.

Much of the text has been entirely changed from the two previous editions, and almost 100 pages have been added. There has been marked improvement in the description of the nervous system, also the liver, heart, and perineum.

This book is an excellent ready reference to practical anatomy and although it is essentially for the student of anatomy, it can serve the practitioner of medicine and surgery at all times.

H. T. WIKLE.

SURGICAL PATHOLOGY. By WILLIAM BOYD, M.D. Third Edition. Octavo of 866 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$10.00.

That the surgeon may properly evaluate the various surgical conditions that come under his observation, a knowledge of their underlying pathology is highly essential. In this book the author presents very clearly the gross and microscopie appearanees of the diseased organs as encountered in surgery. Equipped with a knowledge of these the surgeon may visualize the disease process and institute proper measures for its control. The text contains only essential features and is devoid of anything superfluous. In this third edition the author has incorporated new material such as sections on the metabolism, etiology and action of radium on tumors, chronic follicular gastritis, lesions of the appendices epiploicae, etiology of cholecystitis, cholecystitis glandularis proliferans, and cholesterolosis of the gall bladder. There are also new chapters on the thyroid, and the goitrigenous action of cabbage, autolytic peritonitis, high temperature death following cholecystectomy, obstruction of the common bile duct and many others. There is also a chapter dealing with bacteriology and laboratory procedure insofar as these are rleated to surgery. The text is amply illustrated and contains several colored plates. It is printed in an easily readable type and should prove interesting to anyone interested in medicine or surgery.

E. H. Nidish.

MINOR MALADIES AND THEIR TREATMENT. By LEONARD WILLIAMS, M.D. Sixth Edition. 12mo. of 420 pages. Baltimore, William Wood & Company, 1933. Cloth, \$3.75.

This book on minor maladies is already well established in England where it is now enjoying its sixth edition. The remedies the author recommends may be well recognized on the other side but to an American they appear novel. For example, in foggy weather and in times of epidemics he advises that the inside of the nostrils should be washed twice daily with soap and water. Gargling with soap and water is also mentioned. From the standpoint of germicidal effect it is probably true that soap is more efficacious than

any of the so-called antiseptics now in use. In certain ways this book is of value especially for the general practitioner. It is extremely personal in its approach and reminds one of the household medical guide except that this one is written for the family doctor. And if we should take issue with certain of the things he has to say let us admit that we are often blind to the fallacies of our own teachings,

There are a number of old-fashioned "gun-shot" prescriptions. The writer also gives generous publicity to various patent medicines. And as distance lends charm we cannot help but forgive the author for what on this side of the ocean would be regarded as a lack of propriety. He has so many remedies to offer for any symptom that the physician may turn to any page while his patient is not looking and hit upon something which may make of him a "great physician."

The information is choppy and there is a smattering of diagnosis here and there but the main thing is to give the doctor a remedy and while a number of them are no doubt in accord with our methods of procedure others are in the nature of "fillers," something to give an air of distinction to the book. The occasional case-reports are so fragmentary as to remind one of the drug-concerns which have their fill of case histories to boost their products.

All in all, we would say that this book has some good points although they are few. It reminds one of the good-hearted family doctor who is willing to pour his heart forth with his goodness to tell you everything he knows and does not know.

EMANUEL KRIMSKY.

HISTOPATHOLOGY OF THE PERIPHERAL AND CENTRAL NERvous Systems.. By George B. Hassin, M.D. Octavo of 491 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$6.00.

In the last decade neurology has developed from a science based upon faets of elinical observations to one built upon pathological investigations. Unfortunately, the reports of the various pathological studies have been published in highly technical journals that are not always accessible even to neurologists. For some time there has existed a need for an authoritative book on neuropathology that should be within reach of every physician.

The book that Dr. Hassin has written, admirably supplies this want. The author has been an active worker in neuropathology and a leader in this field for many years. His pupils are to be found in every part of this country and also in forcign countries. He has earned a well merited reputation as a neuropathologist of the highest type, and as a teacher who gives freely and willingly of his time and knowledge. The book that he has written is one that should take its place amongst the classics in medicine. The text is clear and well presented. The two hundred and twenty nine illustrations are most illuminating and well printed. Technically it is of the finest character.

There are four parts to the book; the first deals with the diseases of the peripheral nerves, the second with the diseases of the spinal cord, the third with the diseases of the brain, and the fourth contains the various staining methods utilized in neuropathology. In all there are twenty-nine chapters, at the end of each there is a bibliography containing a selected group of references not only to works of American authors, but to numerous foreign works.

Those who are familiar with Dr. Hassin's work, will welcome the book most cheerfully. To every worker in medicine the book will appeal very strongly. To the medical student it will be an indispensable textbook. To neurologists it will prove most valuable. In brief, the book is a milestone not only in neurology but in medicine as well.

IRVING J. SANDS.

ARTERIOSCLEROSIS: A Survey of the Problem. A publication of the Josiah Macy, Jr. Foundation. Edited by EDMUND V. COWDRY. Octavo of 617 pages, illustrated. New York, The Macmillan Company, 1933. Cloth, \$5,00.

The Josiah Macy, Jr. Foundation has collected under the able editorship of Dr. Cowdry, a series of nicely interrelated papers on various aspects of our present knowledge of arteriosclerosis. The authors should he listed in any review of this book. They are:

N. Anitschkow
Ludwig Aschoff
E. T. Bell George R. Minot
Daniel Blain William Ophnls
Crighton Branswell
Stanley Cobb
Alfred E. Cohn
E. V. Cowdry
Herbert Fox
Herbert Fox
Jonas S. FriedenwaldGeorge Dee Williams
Howard T. Karsner
Fritz Lange

The work contains a vast amount of information, and perhaps an even more striking compilation of things we do not know about arteriosclerosis. This challenge to the investigator is perhaps the primary object of the work, but there is so much of positive value that it should be in the hands of every student of the subject. The bibliography refers to over 800 authors.

TASKER HOWARD.

THE PRACTICAL MEDICINE SERIES. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1932. Chicago, The Year Book Publishers, [c. 1933]. Derinatology and Syphilology, edited By Fred Wise, M.D., and Markon B. Sulzerger, M. D. 12 mo. of 471 pages, illustrated. Cloth, \$2.25.

This is the first time that this Year Book has been published without including, also, the year's review in Urology. The editors are to be congratulated for making the suggestion, and the publishers are to be eomended for seeing the advisability of following the suggestion.

The articles reviewed have been well chosen from American and foreign literature, and the reviews have been very carefully and efficiently done. The grouping of the reviews under the several headings for different types, or classifications, of skin diseases is quite satisfactory and makes for facility in getting at the information desired.

There are approximately 450 pages of text, nearly 100 of which are devoted to Syphilis and its therapy. In attempting to review it one finds so many interesting items that he wants to read it page for page—whether because it is a review of a foreign article not previously seen, or for refreshing his memory on the high spots of a familiar article read during the past year.

seen, or for receiving his memory on the high spots of a familiar article read during the past year.

This is by far the best Year Book on Dermatology in the series.

E. Almore Gauvain.

THE Mode of Action of Drugs on Cells. By A. J. Clark, M.D. Octavo of 298 pages. Baltimore, The Williams & Wilkins Company, 1933. Cloth, \$6.25.

When a physician prescribes a drug for a patient, he usually thinks in terms of Qualitative Pharmacology. He knows that cocaine is a local amoesthetic or that morphine is a central depressant. How these drugs act on the cells of the hody does not command his attention. This book, which is essentially a monograph on Quantitative Pharmacology, attempts to elucidate the mechanism and manner of aclion of drugs on cells. The author tries to discover the laws of combinations formed between drugs and cells, and

seeks the application of laws of physical chemistry. He compares eells with charcoal and studies adsorptive properties. He parallels observations on permeability of non-living membranes with that of the membrane of living cells. He concludes that the reactions between drugs and eells represent a far more complex phenomenon than laws of physical chemistry can explain. He is very conservative and very critical in his interpretation of the literature on the subject.

He presents the living cell as a physico-chemical system and uses free-living cells or unicellular organisms such as sea-urchin eggs, bacteria and red blood cells as examples. He shows the difference in size between the surface of a cell and the molecular size of drugs. He points ont that the most potent drugs can affect cells in such remarkably minimal quantities as 1 part in 1,00,000,000 for calciferol (crystalline vitamin D). Under such circumstances then it appears that only 10 molecules of these substances are enough to act on cell membranes. He shows that cell membranes are made of "patches" which are localized spots on the membrane laving a selective or vital affinity for certain drugs and that the entire cell does not play a part in drug actions. He concludes therefore that it is not necessary to consider laws of physics and chemistry as applying to these drugs in their action on cells.

The author presents a chapter on various theories regarding drug action and includes the Potential Theory of Straub, the Arndt-Schulz Law and the Weber-Feelmer Law. He presents the last law as the most promising theory. There is also included a chapter on the mode of action of hormones and vitamins on cells. Here he reviews the literature dealing with the more intimate relationship between cells and these substances and discusses their inechanism of action,

It is an important book and illustrates the future trends in studies and interpretations of the action of drugs on cells.

WILLIAM S. COLLENS.

The Joy of Living. An Autobiography. By Franklin H. Martin, M.D. Two volumes. Octavo of 1017 pages, illustrated. Doran & Company, 1933. Cloth, \$7.00.

Dr. Martin has written his autobiography in two fine volumes. The second is devoted almost entirely to his reminiscences of the World War, and his experiences in Washington during the mobilization of the American Medical profession for overseas service. The story of his work on the Advisory Commission of the Council of National Defense is well told. We all owe him a great debt of gratitude, for it was largely through his vision, courage, leadership, and executive genius that the medical profession took its proper place in the great conflict.

The first volume is even more interesting. His picture of his boyhood in the Wisconsin wilderness is stirring. Schoolmaster, farm hand, brickmaker and carpenter, he was never afraid of work, and received very little for it. His student days at Chicago Médical College, in two rooms for which he and his room mate paid four dollars a month should be an inspiration to every boy studying medicine,—the finest chapter in the book.

The detailed record of his greatest work, the organization of the American College of Surgeons, should be read by all who are familiar with the aims and achievements of the College, yet the reviewer can not help but wonder if he has told us all.

Most astonishing of all, he was born in 1857, yet he is still in the prime of life. Surgeon, dreamer worker and peerless executive, his life is a great record of achievement. It is good that his autobiography has been written.

CHARLES A. GORDON.

OUR NEIGHBORS

HUMAN STERILIZATION IN CALIFORNIA

The September number of California and Western Medicine has a comprehensive account of the working of the human sterilization law which was enacted by the Legislature of California in 1909, and has been extensively applied to mental defectives since 1918. The article is a study of 2,264 cases of sterilization which have been done in the Sonoma State Home (for the insane). This is slightly over one half of those discharged from the institution. Over two thirds of those discharged had made a satisfactory adjustment to social conditions. Commenting on

the results, the article says:

"Of the above number discharged, a large proportion are successfully married, the majority with our permission and with the policy of being married for approximately two years before being discharged. Of this number of marriages. their success as to married life, being measured by the number of annulments and divorces, compares favorably with normal individuals. Marriages assist materially in stabilizing the defectives, and we credit considerable of their successful adjustment to successful marriage and we believe they should have this privilege in that they are unable to propagate, owing to the operation before leaving the institution. Some of the higher type have been permitted to have one or more of their children, which were born before admission. It makes for a very happy home, although they are not able to have additional children. The vast majority, however, do appreciate and are glad they cannot have more children, realizing their inability to properly care for them. The great majority of the mentally deficient do well to support themselves, even under guidance, without the added responsibilities of having children to

The article closes with a report of a pamphlet on "Human Sterilization," published by The Humane Betterment Foundation, suite 321, Pacific Southwest Building, Pasadena, California. This pamphlet explains the results of the appli-

cation of the law and says-

"At the present time there are twenty-five states and four foreign countries with sterilization on their statutes. We are glad to report, however, that other states and countries are giving the matter very serious consideration. By the material aid of organizations, such as the Human Betterment Foundation of Pasadena, headed by E. S. Gosney, philanthropist and founder, we are hopeful that such laws will get on the books of the remaining twenty-three states of the Union and all the civilized countries in the world. From our actual experience over many years, it would seem that everything points in favor of giving these individuals this protection against parenthood, and the longer we are in this work the more we advocate eugenical sterilization for the protection of society and the furtherance of human betterment.

"The patients sterilized in the California institutions were found in six cases out of every seven to be satisfied with the operation and the results. The exceptions were only such as would be expected in a group of persons who had gone

through severe mental illness.

"In no case has the operation broken up a home or disturbed a family relationship. On the contrary, case after case might be cited in which sterilization has been responsible for keeping a family together and allowing the patient to remain in his own home instead of spending the

rest of his life in an institution.

"A canvass of the medical officers, probation officers, parol authorities, and social workers of the state who have had close observation of the workings of California's eugenic sterilization law disclosed that they are virtually unanimous in its support, holding it to be desirable in principle and satisfactory in practice. The criticism most frequently voiced by them is that it is not applied more widely. While nearly all of the feebleminded are sterilized before released from state institutions in California, only one in twelve of the insane has been sterilized during the life of this law."

COUNTY SOCIETY NEWS IN MISSISSIPPI

The Mississippi State Medical Association has a system of county editors for reporting local medical items to the New Orleans Medical and Surgical Journal. The Journal for November contains the following excellent report from Dr. G. S. Bryan of Monroe County:

"Whew! Wasn't September a scorcher?

But October, I hope will be better. At least, it has opened up nice and cool.

"All my doctors are in good health, but they are pretty busy, I think. It is evident that we are having more malaria to deal with than we have had for several years. However, we do

Rever advertised to the public

"The dextrin-maltose preparations possess certain advantages. When they are added to cow's milk mixtures, we have a combination of three forms of carbohydrates, lactose, dextrin and maltose, all having different reactions in the intestinal tract and different absorption rates. Because of the relatively slower conversion of dextrins to maltose and then to dextrose, fermentative processes are less likely to develop. Those preparations containing relatively more maltose are more laxative than those containing a higher percentage of dextrin (unless alkali salts such as potassium salts are added). It is common experience clinically that larger amounts of dextrin-maltose preparations may be fed as compared with the simple sugars. Obviously, when there is a lessened sugar tolerance such as occurs in many digestive disturbances, dextrin-maltose compounds may be used to advantage." (Queries and Minor Notes, J. A. M. A., 88:266)

not report nearly as much as formerly: for we have stopped calling everything we meet malaria. Our county laboratory has been worth untold sums to us and our people. The saving in quinine, alone, would pay the running expense of this laboratory. When I was acting county health officer, my doctors would report thousands of cases of malaria in a single month. I knew this was wrong. After I had succeeded in establishing this diagnostic laboratory the incidence of malaria crumpled at once. Now, our doctors rarely treat or report a case as malaria until the diagnosis is verified. We have a most efficient technician and the hardest worker I ever knew. She made and reported an examination for every seven minutes of her working hours in the month of September. These specimens—all kinds—are sent in to her and she phones reports to the doctor sending them immediately after examination. Our people are completely sold on the idea and appreciate the service more than they do any public service they get. This laboratory is not in competition with any commercial laboratory; for the people could not pay for this service. And the poorest people as well as the more well-to-do get the service, just the same. I am convinced that more of our recent graduates in medicine would locate in the rural districts if they knew they could get laboratory help in their work. I maintain that the country people are entitled to the best medical and hospital service that can be given any people. The county laboratory and community hospital is the solution of this crying need and perplexing question. Correct diagnosis is fundamental in scientific practice of medicine. And any other kind of medical practice is criminal. These last two statements lead me to wonder if we, doctors, keep our records and our consciences clear and clean in our dealings with the sick and near sick? I wonder if we do not encourage, and even, practice a little Voodooism? It is so easy to look at a tongue, insert a thermometer, write a prescription and charge two dollars (then collect it if we can)."

GRADUATE COURSES IN VIRGINIA

The annual report of the Department of Clinical Education of the Medical Society of Virginia is contained in the October issue of the Virginia Medical Monthly, which says:

"The duty of the Department of Clinical Education is to stimulate and assist in the holding of scientific programs by the component societies. Its appropriation, reduced this year to \$400, has been expended for defraying travelling expenses of clinicians and for announcements and notices concerning clinical meetings. The Clinch Valley

supporting treatment is essential. Fellows' Syrup is the most logically prepared tonic at the disposal of the physician.

It contains all the required minerals in correct proportion and in an easily assimilable form. These are Manganese and Iron to renew the blood stream impoverished by continued loss; Calcium to replenish the constant calcium depletion; Potassium, Sodium, and Phosphorus to overcome the neural depression; Strychnine as a tonic to cell metabolism; and Quinine as a gastric stimulant.

There is no better tonic than Fellows' Syrup to the parturient and post-parturient patient. During these trying periods, the suggested dose is one teaspoonful three times daily well mixed with water.

Medical Society has continued to arrange for invited speakers through the Department. such speakers went from Richmond to the meeting in October, two in April, and two more have been scheduled for the meeting this September. The Medical Society of Northern Virginia, the Danville-Pittsylvania Academy of Medicine and the Augusta County Society have secured speakers through the Department. The regular clinics held at the Medical College of Virginia and the University of Virginia Hospital are well received by the profession and are emphasized in notices and announcements of the Department.

"Besides the oversight of the program of instruction in prenatal and postnatal care, (a detailed report of which is attached,) the Department's major concern during the year has been the establishment of clinics in pediatrics, the subject chosen as the preferred study by the majority of members of the courses in prenatal and postnatal care. Dr. Frank D. Wilson and Dr. W. P. Tackson, chairmen of the child welfare committees of the Pediatric Society of Virginia and of the Medical Society of Virginia, requested the Department to institute a program of pediatric instruction in all parts of the state by means of classes arranged in circuits.

"At the time this report is drafted, the Joint Committee has completed one year and four months of the two-year program of intensive postgraduate instruction in prenatal and postnatal care first authorized by the Medical Society at its meeting in Roanoke in 1931 and unanimously approved at its Richmond meeting in 1932. On both occasions an annual appropriation of \$2,500 was voted to supplement the grants of the Commonwealth Fund.

"By the 15th of September Dr. Lapham, the Joint Committee's Field Clinician, will have completed thirty-three courses of twenty hours' instruction. Except for two short courses of two weeks each on the Eastern shore and in Bedford, the classes have been arranged in circuits so that the instructor spends one day each for ten weeks in the class center. Three hundred and twentyseven meetings have been held, each with an average of fourteen present. The physicians who are members of these classes—membership including those who signed the enrollment card and attended at least once and those who without the formality of enrolling attended at least four times -total 421. These members, on the average attended three-fourths of the meetings. In addition over 150 visitors were present, chiefly physicians but including internes, medical students and nurses not eligible to membership. In every case, in conformity with the instructions of the Medical Society at the inauguration of this program; the organization of a class has been under-

taken only after it was approved by the local profession. Nearly forty societies have formally voted their endorsement of the course, every vote being unanimous except one. After approval for organization was given, every community to which Dr. Lapham's services were offered has carried through the formation of a class.

"The Field Clinician has reported the demonstration of 220 clinical subjects in classes, and the examination of 403 patients in educational consultations held at the request of individual physicians. The increasing emphasis upon the individual conferences is due to the desire of members to secure expert instruction in their own problems, and in part, the Field Clinician reports, to the fact that the chief handicap to the complete success of the work is the inability of the local groups to arrange for an adequate supply of clinical material.

"While the lack of clinics has been the one source of complaint about the program, the comments of the members themselves prove their high regard for the advantages of their study. In the written comments which each member is asked to furnish anonymously, 213 of 219 replies have rated the lectures as excellent or good, 100 of 189 replies consider the clinics either excellent or good, 204 of 210 replies consider the course worth the cost in time and money, and 200 of 206 desire further courses in other subjects. The subject most generally preferred is pediatrics with a vote of eighty-five."

The financial report of the work for the year ending April 30, 1933, is given as follows:

CARITOL, for A, alone-

Catitol is a 0.3% solution of Carotene (C,H,s), the palatable fruit and vegetable form of vitamin A, and therefore represents the form in which most vitamin A is naturally consumed by the human body.

Helps Build Resistance and Promotes Growth

Catitol, by virtue of its vitamin A activity, promotes growth and, as indicated by experimental studies, may be an aid toward the establishment of resistance of the body to infections in general. It may be prescribed alone or with CAPSULES OR DROPS other vitamin products. There is INSTEAD OF no fishy taste or bad after-taste. The cost is reasonable, too. Caritol is available in 15 c.c. and 50 c.c. EASY DOSES dropper-rop bottles and in capsules NO FISHY TASTE NO AFTER TASTE packed 25 and 50 to the box.

CARITOL-with-Vitamin D

Catitol-with-Vitamin D is

on the market because it contains the fruit and vegetable form of vitamin A, carotene, and a tasteless vitamin D prepared for therapeutic use by methods (Zucker process) developed at Columbia University. It is naturally palatable, not artificially flavored.

For A and D, together in Palatable Form

Caritol - with - Vitamin D is, therefore, especially recommended for patients who need both vitamins A and D. but object to the fishy taste of fish liver oils and their concentrates.

> There is no fishy taste or bad aftertaste, and the cost is reasonable. Available at prescription pharmacies in 5 c.c. and 50 c.c. dropper-top bottles and in 25-capsule boxes.

Prescribe these naturally palatable vitamin products - they cost no more.

Taste the carotene products yourself. Write for samples. We also offer Smaco Cod Liver Oil fortified with carotene and vitamin D for those physicians who prefer to prescribe cod liver oil. It is three times as potent in both vitamins A and D. Therefore one teaspoon is equivalent to three teaspoons of good grade cod liver oil. Improved flavor and minimum cost to patient. For vitamin D alone (for the prevention or cure of rickets), we offer Smaco Vitamin D, a highly potent extract of the antirachitic principle of cod liver oil prepared by methods (Zucker process) developed at Columbia University. Ten drops equivalent in vitamin D potency to three teaspoons of good grade cod liver oil.

GRADUATE INSTRUCTION IN MISSOURI

The November number of the Journal of the Missouri State Medical Association has the following editorial description of graduate instruction in the subject of cancer:

"At the Kansas City Session of the Missouri State Medical Association the Committee on Cancer presented a recommendation that an educational campaign on cancer for both lay and professional groups be inaugurated in conjunction with the Committee on Post-graduate Course and the state committee of the American Society for the Control of Cancer. The recommendation was approved by the House of Delegates and the program has been prepared and the work begun.

"The Committee on Cancer and the Committee on Post-graduate Course have formulated plans for one-day cancer programs wherever such programs would be effective. The State has been divided into five districts and teams have been organized in various centers of the State. These teams are composed of physicians qualified to speak before lay and professional audiences and to give dry clinics on cancer.

"Each program will include a large public meeting for lay education: a dry diagnostic clinic for the benefit of the local medical profession, and a scientific program in the evening for a joint meeting with the county medical societies.

"Cancer of the breast will be the topic of the

programs during this year.

"The State has been apportioned in groups

of Councilor Districts.

"The Woman's Auxiliary through Mrs. Floyd H. Spencer, St. Joseph, chairman of the Committee on Public Relations of the Auxiliary, has volunteered to assist at these meetings by using their influence in the counties where the lectures are given to encourage a large attendance of citizens at the public meetings.

ings

"Under the guidance of the Cancer Committee and the Post-graduate Committee with the State committee of the American Society for the Control of Cancer, this work is now well under way and promises to be a powerful influence in arousing an intelligent cooperation of the public with the medical profession to gain the first and the vital objective in the fight against this menace; namely, the early recognition of cancer.

"To the physician who sees few cases of cancer a knowledge of the early symptoms is absolutely essential. Therefore, he must be told

"To the physician expert in the recognition and treatment of cancer these meetings should bring renewed enthusiasm in spreading the knowledge among his patients and among his confreres.

EMERGENCY MEDICAL RELIEF IN FLORIDA

The October issue of the Journal of the Florida Medical Association, Inc., contains an editorial comment on the work of the Medical Economics Committee of the State Association. describing a meeting of the Committee in October. the editorial says:

"Mr. Marcus C. Fagg, Florida Director of the Federal Emergency Relief Administration was present, by invitation, and assisted materially in clarifying certain phases of the Florida Physician-Federal Relief relationship. A considerable portion of the morning session was devoted to a discussion of this subject with particular reference to determining a satisfactory and fair fee basis for professional services to recipients of unemployment relief, it having been definitely stated by the Director that uniform fees must prevail for the entire State.

The Committee desires to submit the following recommendations':

"I. That each County Society seriously consider contracting with its various municipal and the county governments to furnish medical services to the indigents of these political units; that the County Society supervise the service rendered and that the funds received from such contracts be paid into the Society's treasury to be used for the scientific, economic and social interests of its members.

"II. That there be no free examination or vaccinations of children by County Society members. Those who are indigent should be provided for as suggested in the preceding paragraph. Those who can pay should secure the services from the family physician.

"III. We believe that it is impossible for any man, no matter how honest and conscientious he may be, who is serving as part-time employee of the county or city and part time in private prac-(Continued on page 1420-adv. xx).

tice to be able to render adequate service when his private income is being neglected.

"We therefore recommend that county and city physicians be paid an adequate salary and that they not be allowed to do outside practice for which they expect to receive remuneration, and that these physicians be required to render their services only to such patients as have been investigated and found to be without the non-necessities. In this way those physicians who are now overburdened with charity work will receive ade-

The "FINGER-LOCK" FORM of MATERNITY SUPPORT

THE principle of diagonal adjustment and uplift is applied to maternity supports in this new creation in the line of S. H. Camp & Company. It embodies the latest theories of eminent obstetricians and has elicited the approval of doctors generally.

Distribution of weight to a much broader surface of the back and continuous uplift without constricting lines are improved features that alleviate undue abdominal pressure and restore more natural equilibrium.

Two sets of wide adjustment tabs are attached at a low abdominal point, directing traction two ways: (1) one extending in a truss line to the back for sacro-iliac support; (2) the other carrying the weight in a diagonal "finger-lock" upward to a point well above the lumbar region. The back line reaches down well under the gluteus.

This support employs the exclusive Camp continuous lace adjustment—also side lacings for maternal development.

SPEAKERS' BUREAU IN IOWA

Medical The Iowa State Society has an active "Speakers' Bureau," which reaches not only ay groups, but also medical societies. It assigns physicians to address lay groups such as women's clubs, parent-teachers associations, and high school classes, and pays the expenses of those who are sent out.

The Bureau also provides speakers for scientific groups, such as those of dentists, nurses and pharmacists, and demonstrators at medical clinics, and especially speakers for county society programs. The Bureau seems to have some difficulty with the question of publicity accruing to the speakers, for the October Journal of the Iowa State Medical Society announces that "every effort is made to avoid sending a doctor too far, yet at the same time far enough so that his talk may in no way be construed as an advertisement of his own medical services." The same issue of the Journal

also contains the following account of the graduate courses managed by the Bureau.

"Fall and the reopening of schools, colleges and universities have started the trend of students back to school and studies. Not to be outdone by the 'younger generation, Iowa physicians, about 300 strong, have enrolled for the fall postgraduate courses given by the faculty members of the College of Medicine, and sponsored by the Speakers' Bureau.

"The work being offered this fall consisits of two courses; one a combined course on obstetrics and pediatrics, given by Drs. E. D. Plass and P. C. Jeans; and the other course on diagnosis and treatment of common medical disorders, under the direction of Fred M. Smith, M. D. The courses began at Algona at 5 p.m. on Monday, September 26, where over 60 members have signed up for the work. The courses will continue for

period of ten weeks on the same day for each center as the day on which it started. The other centers where the courses are being given are: Jefferson on Tuesday, where about 35 doctors have enrolled; on Wednesdays at Des Moines, where the courses have been made available to each member of the Des Moines Academy of Medicine and Polk County Medical Society; and on Thursdays at Marshalltown, where there is an enrollment of over 50.

"From reports made at a recent meeting of state medical society secretaries on postgraduate medical education, it is evident that Iowa is doing more work along this line than almost any other state. The interest in this type of work has grown by leaps and bounds since its inauguration in 1929. With the fall courses just under way, demands are already coming in from several centers for spring courses."
This Journal also describes

the "Mecting of Merit," by which title it honors the society which puts on the best meeting of the month. The report says:

"However, the meeting which has been awarded the distinction of "Meeting of Merit" for September is the meeting of the Tenth District Medical Society at Creston, on September 22. Doctors were present from every county in the district and great interest and enthusiasın were shown in meetings of this type. In the afternoon a chest clinic was held. After an enjoyable dinner and social hour. at which time short talks were given by officers of the State So. ciety, the following program was presented on the following suliects by local speakers:

Perineal Lacerations, Spinal Anesthesia, Endocrine Therapy of Menstrual Disorders, and Experiences in Vienna.

'The Bureau commends this type of program in particular because it is fulfilling the primary aim of a medical society, which is the development of its own mem-

FOR THE DIABETIC

There is now available for diabetic patients, a Lilly Ever-Aseptic Iletin Syringe Case at a new low price within the reach of nearly every patient who uses Iletin (Insulin, Lilly). The reduced price is made possible largely through the use of a new chrome nickel alloy steel needle which is said to be very satisfactory and much less expensive than the platinum needle formerly supplied. The completely assembled package contains a handsome metal case, in which there is a specially graduated syringe for Iletin (Insulin, Lilly), two chrome nickel alloy steel needles, a compact cotton container, and a small sterilizing flask. For extra needs, there is a box of absorbent cotton, a four-ounce bottle of isopropyl alcohol for sterilizing, and a glass pipette for use in transfering alcohol from the bottle to the small flash. Some extra stoppers are also supplied.

Repair Electro-Diagnostic Instruments

We maintain a well equipped plant for the repairing and over-hauling of all makes of Cystoscopes, Eye, Ear, Nose and Throat Instruments, etc., Cautery and other Electro-Medical Apparatus. When we do your work, you can be assured your equipment is entrusted to competent eraftsmen.

This outfit is said to be a great convenience for patients to use in the home, while traveling, or in the office. The case can be carried easily in the pocket or in the purse. Its use eliminates danger of infection and permits wider activity of the patient. Pharmacists have these cases in stock or can supply them on short notice.—Adv.

WHAT IS CARITOL?

For ages, man has eaten certain palatable fruits, vegetables and dairy products to satisfy his hunger. His body requirements for vitamin A like, no institutional appearance.—Adv.

were thus unconsciously satisfied in greater or less degree.

The substance responsible for this vitamin A activity has recently been shown to be carotene, a yellow organic pigment (C₁₀H₅₀), called Primary Vitamin A by Sherman and Smith in 1930.

The prevalence of latent vitamin A deficiency diseases suggests to numerous investigators that modern diets do not contain enough carotene to fully satisfy the requirements of many individuals.

The fact that carotene is normally present in various parts of the body, blood, breast milk, etc., would seem to indicate that in addition to its activity as a vitamin, carotene itself meets other body requirements besides its conversion into the colorless product by the liver.

If this deficiency is to be made up, what is more natural than to supply the same palatable substance, carotene, derived from vegetables, in concentrated form?

This is now possible. S.M.A. Corporation, world's largest producer of carotene, offers physicians a highly potent solution containing 0.3% carotene (Primary Vitamin A) in drop of capsule form at most pharmacies. The name is Caritol.—Adv.

KALAK WATER

Many diseases are complicated by an "acidosis." An important part in their treatment consists in replacing those elements needed to maintain the alkali reserve.

In clinical practice a rational and agreeable method of alkalinization is afforded in Kalak Water.—Adv.

THE DIAGNOSIS OF GLAUCOMA SIMPLEX

By S. B. MARLOW, M.D., SYRACUSE, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933,

 LAUCOMA SIMPLEX has been called T posterior glaucoma in contrast with acute or chronic congestive, or anterior glaucoma. The relationship between these two types of discase is not definitely known. It has been suggested that simple glaueoma is a compensated form of the disease, the change from one form to the other having been observed not infrequently. Furthermore the differential diagnosis between the chronic congestive and the non-congestive form is sometimes difficult to make. In both instances the disease is bilateral although the eyes may be effected at different times. The fact that the ultimate termination is blindness if untreated, and unfortunately sometimes in spite of treatment, makes its recognition in the incipient stages of extreme importance.

Diagnosis, therefore, has two aims—(1) the determination of the presence or absence of the disease and (2) the recording of its progression.

Simple glaucoma is characterized by its insidious onset, its freedom from pain and the

slowly progressive loss of vision.

Because of the fact that central vision remains good until late in the course of the disease these patients too frequently do not come for examination until the characteristic triad of symptoms—increased tension, cupping of the dise, and changes in the visual field—is well established. The making of a diagnosis in the incipient stage will be dependent upon the keenness and thoroughness of the ophthalmologist in conducting his examinations.

The characteristic features and the important points in the diagnosis of this disease are well illustrated in a review of a series of 115 cases the majority of which have been observed by my father, Dr. F. W. Marlow.

Eighty-two cases presented a history from which it was possible to estimate the probable duration of the disease prior to its diagnosis. The average probable duration was found to be 2.8 years, the shortest 2 months, the longest 15 years but in this case there was a suggestion that the disease had been previously diagnosed. In 33 cases the

diagnosis was made before any suggestive symptoms were apparent to the patient. Some of these cases were old patients returning for refraction.

Fifty-four patients were male, 61 female. The average age was 59½ years. There were 48 cases under 59, 67 cases 59 or more. The youngest patient was 16, the oldest 86. While these figures indicate that the disease is more common after the age of 50, in agreement with other reports, they emphasize the necessity of constantly being on the lookout for its presence at an earlier age. 41.7% of the cases were below the average age of this series.

The commonest symptom which constituted the chief complaint was gradual failure of vision in 54 cases. Blurring or fogs came next in 27 cases. In 24 eases the patient came with complaints about their glasses, believing that a change was indicated. Ten complained of difficulty in reading. Seven patients had noticed halos but had had no pain and 6 had accidentally noticed the loss of vision of one eye. Headache was noted in five cases. Other symptoms included foreign body sensation, 4 cases, difficulty in the dark, 3 cases. Many other minor symptoms were present but these constitute the outstanding complaints. It is interesting that in 30% of the cases the chief complaint had some reference to glasses and the need of a change. In 3 cases there were notes of previous examinations by optometrists.

The relationship between glaucoma and the refraction of the eye is well known. In this series 75 cases were hyperopic, 21 myopic, 6 had mixed astigmatism and in 13 the refraction was not noted. The myopia was less than one diopter in 11 cases, from 1 to 3 diopters in 8 cases, 8 and 11 diopters in 1 case, 4 and 9 diopters in a second. Thus it appears that glaucoma is not common with high degrees of myopia.

Premature presbyopia has been described as an early or premonitory sign of glaucoma and is explained by pressure affecting the nerve supply of the ciliary muscle. In this series of eases this symptom has not been observed. On the other hand, premature presbyopia has not infrequently

been observed without the subsequent development of glaucoma. This leads us to suggest that premature presbyopia has been unduly emphasized as an early symptom of glaucoma simplex.

The insidious nature of simple glaucoma is strikingly illustrated by the tabulation of loss of vision present in this series when they were first examined. (Table 1.)

Vision of	THE	Worse	EYE	ΑT	THE	FIRST	Examination
-----------	-----	-------	-----	----	-----	-------	-------------

No Light Perception or Enucleated 6/60 or less. 6/24 or less. 6/12 or less.	31 Cases 24 " 14 " 10 "	26.9% 20.8% 12.1% 8.7%
6/12 or less	10 " 36 "	8.7% 31.3%

TABLE 1

A disease which results in considerable damage to the vision of one eye in nearly 70% of the cases before the patient is sufficiently aware of his condition to seek aid can truly be called an insidious disease. The insidious nature of the disease is undoubtedly responsible for this considerable loss of vision which may develop before some accidental or deliberate shutting of the better eye discloses it.

A further explanation is to be found in the tabulation of the remaining vision in the better eye as follows (Table 2):

6/ 5 6/ 6 6/ 9 6/12	37 " 20 " 14 "	10.4% 32.1% 16.5% 12.1% 27.8%
Worse than 6/12	32 "	27.8%

TABLE 2

Examination of this table shows in comparison with the first that whereas 70% of the cases have a considerable loss of vision in one eye only, 28% have a high degree of loss of vision in both eyes.

The tension was measured by the Schiotz tonometer (old model) in 72 cases. The remaining 43 cases were observed before the introduction of the tonometer for the most part. The average tension for 131 eyes was 36mm, the high-

est was 80mm, the lowest 12mm. In 82 eyes, or 63%, the tension was 36mm or less and in 49 eyes, or 37%, it was more than 36mm. The following table represents the relationship between the tension and the duration of the disease prior to observation in 52 cases. (Table 3.)

No. of Cases	Duration	Tension var- ied between	Average Tension
26	1 year or less 2 years 3 " 4 " 5 " 6 " 7 " 8 " 10 " 15 "	64-22 53-25 45-25 47-12 72-25 70-47 63 27 43 18 40	43 39 40 29 43 57 63 27 43 18 40

TABLE 3

The average tension from this table would appear to be about 40 mm. regardless of the duration of the disease.

The visual field was definitely recorded in 101 of the 115 cases. Of these 14, or 14%, were recorded as being normal. It is probable that some of them would have shown typical defects if they could have been studied by the more recent methods. One case, carefully followed for 10 years, did not begin to show definite defects in the field of the remaining eye until 4 years after the first examination at which time the tension was 70. In 11 cases the only field defect was a scotoma. In 3 cases scotomata were associated with peripheral changes. In 35 cases there was a beginning or moderate nasal defect and in 36 the nasal defect in the field was advanced. From this it is evident that in 86% of the cases there will be found to be changes in the field of vision when the patient is first examined. The following table seems to indicate that there is likely to be a marked loss even at the first examination and that apparently there is no definite relationship between the degrees of field defect and the duration of the trouble. (Table 4.)

	No Change	Scotoma Only	Scotoma + Peripheral	Beginning Nasal Defect	Advanced Changes
1 Year or less. 2 Years 3 " 4 " 5 " 6 " 7 " 8 " 10 " 12 "	6 5 1 	7 i i 	3 	21 4 1 2 2 2 2 2 	26 5 2 2 2

This may be due to the uncertainty with which the probability favors the idea that the disease had been present long before symptoms were apparent. It is possible that there may be some relationship between the rapidity of onset and the rapidity with which the eye adjusts itself to the increase of tension. In a smiller group selected from this series to be discussed later there seemed to be no definite relation between the degree of tension and the field defect. Seventy-one per cent of the 101 cases had marked field changes when first seen

Among the less frequently noted changes which may sometimes be helpful in the diagnosis is the state of the anterior chary veins. These were sufficiently striking to be especially mentioned in nine cases of this series, two of these occurring

with a low tension

In 69 cases the pupils were noted as normal in 27, sluggish in 22, large in 20. There were no strikingly abnormal changes in common with the usual description of the disease. In 56 cases the anterior chamber was described as normal in 35,

deep in 14, and shallow in 18

Cupping of the disc is one of the cardinal signs of simple glaucoma and very often the diagnosis is first made on its observation. In 99 cases of this series cupping was described as physiologic in 7, shallow in 8, deep in 13 and characteristic Cupping was doubtful or absent in 17 ın 54 cases In 5 cases the observation of an increase in the physiologic cupping led to taking the ten sion with the confirmation of the presence of When cupping of the optic dise is well established there is no doubt about the diag-The recognition of beginning changes in the disc is more difficult. It has been suggested that sketches depicting the relative size of physic logic cupping at successive examinations will show clearly a significant increase in the size of a Undoubtedly photographs of the disc would prove of even greater value but with this procedure the writer has had no experience. Treacher Collins calls attention as an early symptom to the displacement of the vessels to the nasal side in an eye which shows no other signs This he has ob served in cases where there is a definite glaucoma in one eye and in the other no marked symptoms Careful ophthalmoscopic examination in these early cases is essential for diagnosis

Arterial pulsation is described as a characteristic sign of increased tension in most text books According to Elliott undue emphasis has been placed on it for he has stated that he has never observed it in either simple glaucoma or chronic congestive glaucoma. When present it is a very valuable sign but it occurs much less frequently than the textbooks infer Venous pulsation is usually looked upon as physiologie and is much more commonly observed in young people. It is more marked in children, less so in elderly people According to Loring the venous pulse may be an expression of a disturbance in the equilibrium between the pressures within and without the vessel wall. Elhott believes that, when other features of a case point toward glaucoma, the pres ence of a marked venous pulsation in the retina is a suggestive piece of evidence. Further, the presence of such a marked venous pulsation, whenever it is detected should raise in the observor's mind the possibility of a threatening of glaucoma" This would seem especially true of patients at the glaucoma age-a time when this phenomena is less frequently observed. In this series vessel pulsation was present in 11 of 16 cases with notes. In seven of these it was spontaneous and in 4 appeared on pressure. In 5 cases pulsation was definitely noted as absent

The study of a group of 32 cases selected from these 115 cases on the basis of vision of 6/12 or better in both eyes presents a rather striking comparison with the figures for the whole group of cascs Whereas the average probable duration was 28 yrs for the whole series, in 17 of the selected cases no previous duration could be determined, in 12 cases the probable duration was one year or less, in 1 case 3 years and in two cases four years Thus the duration was longer than 1 year in only 1% In other words in these eases representing 28% of the whole series, the diagnosis was made early in the course of the disease The average tension for this group was 29 mm as compared to 36 mm for the whole series The average age was only slightly lower, being 578 years In this group there was considerable field loss in only 50% as compared to the 70% of the whole group Three cases had normal fields, in 9 cases a scotoma was the only change, and in 3 others scotomata were combined with other de fects. An attempt was made in this group to re-

	No Defect Scotoma Only		Scotoma c Peripheral Changes	Beginning Nasal Defect	Advanced Nasal Loss

N. Y. State J. M. December 15, 1933

late the changes in the field with the tension as shown in the following table. (Table 5.)

Analysis of this table shows no definite relationship between the extent of the field loss and the tension. It would seem to indicate that low tension is harmful in some cases and that in others high tension is not so harmful as might be expected for about the same degree of field defect can be present regardless of the tension of the eyeball.

The question arises as to what is the most reliable sign upon which an early diagnosis of chronic simple glaucoma can be based. Review of the symptoms recorded as the chief complaint in this series would indicate that there is no one which can be considered as characteristic except perhaps the history of gradual failure of vision. The great variation in the objective signs, unless the case is well established, renders it difficult to select any one procedure as entirely reliable for establishing a diagnosis.

In as much as all the essential symptoms of glaucoma can be accounted for as being the results of increased pressure (Fuchs) Haden believes that its discovery prior to the onset of symptoms should be the aim of all ophthalmologists and to this end he urges more routine tonometry especially in the age period in which the disease is likely to occur. Analysis of the tension found in the cases reported in this series seem to indicate that the state of the intra-ocular tension varies much less than any other symptom and tonometry, therefore, would appear at the present time to be one of the most reliable procedures in arriving at an early diagnosis. It should not be forgotten, however, that a low tension, well within the normal limits, is sometimes encountered in cases with other well-marked characteristic signs. While characteristic defects in the field of vision are among the earliest symptoms Traquair states that they are present only after the disease has become established. There are very few cases in this series in which the field failed to show changes. In one of the more recent cases, however, (already mentioned) careful examination with the tangent screen failed to show any defect although the intra-ocular tension was 70 mm.

The work of Derby and his collaborators has shown that the light minimum is increased in glaucoma. These workers believe this to be the earliest detectable sign of this disease. They have devised a portable apparatus with which the test can be made in the hope that this test may become more readily available for clinical use. Until its application is more generally understood its use will be restricted. The fact, however, that the light minimum is increased, that is that a greater amount of light is necessary for its perception by a glaucomatus eye, suggests the possibility of increasing the sensitivity of other clinical tests by

decreasing the amount of light ordinarily used for them. This principle can be easily employed by anyone who cares to develop standards of his own with which to compare observations made in suspected cases. It has been applied by the writer to the examination of the central portion of the field of vision with results which, from the evidence so far obtained, indicate that typical defects can be demonstrated much earlier than when full illumination is used.

The desire to make as early a diagnosis as possible has led to the development of many provocative tests. How frequently they are applied it is difficult to state. Probably the adrenalin test has been used more widely than any other because of its simplicity and relative safety. This test has been used with positive results in but three cases of this series so that our experience has been very We have had no experience with the homatropin test, the Seidel dark room test, the "coffee," "drinking" and "reading" tests, nor with jugular compression. Pressure curves following puncture of the anterior chamber according to Kronfeld have a form typical of glaucoma and are positive when all other tests fail. All these provocative tests depend upon tonometric observation.

The importance of the estimation of the intraocular tension with the tonometer, therefore, can not be urged too strongly as a more routine procedure in patients at the glaucoma age. It is more than likely that more of the cases in the series here reported might have been diagnosed at an earlier stage if this had been done. It is particularly true in a case of high myopia in which the significance of the symptoms was not appreciated until the tonometer demonstrated an elevated tension. A discussion of the proper teclinique for tonometry hardly seems necessary here. Suffice it to say that the patient should be in a reclining position, the lids held away from the globe and from contact with the tonometer and the base-plate of the tonometer applied squarely over the centre of the cornea in such a way that the instrument stands perpendicularly. Accurate readings can only be obtained if the instrument is applied in this manner. Moreover, the measurement should be made with the lightest weight which allows the needle to register between the third and fifth divisions on the scale. This applies especially to the Schiotz tonometer as we have had no experience with other models. further point has to do with the time of day at which the tension is taken. The tension normally is somewhat higher in the morning, the variations according to Gradle being not more than 6 mm. and never above the normal limits. In glaucoma the morning rise is considerable with a sharp fall towards noon, and a gradual decrease during the afternoon. Hagen, Oslo, Norway, suggests that the tension be estimated twice daily, at 9:00 A.M.

and 6 30 PM More frequent observations would, of course, produce a more clean cut curve

Such then are the main points in the establishment of a diagnosis Of no less importance are the methods to be used in watching the course of the disease. From this point of view the fields of vision assume preemmence. Altho successive ob servations may demonstrate no diminution in vis tral acuity, that the tension is being maintained at a satisfactory level, and that the patient is symp tom free, perimetry will demonstrate that the disease is progressing. Therefore, while defects in the field of vision are present only when the disease has become established, their investigation is the best criterion upon which to judge its prog ress and to make decisions in regard to treatment Contraction of the peripheral field and the development of scotonia or their further enlarge ment are definite indications that the treatment is Such field studies should be made under identical conditions. The observation of the tension is of almost equal importance. If the tension is not being properly controlled the treatment, whether medical or surgical, has become meffec tive and further steps must be considered

In reviewing the series of cases here reported the following observations seem permissible

(1) that the duration of the disease prior to its drignosis is longer than it should be owing to its insidious nature and the fact that central visual acuit is not affected in the early stages

(2) that it is possible to make a diagnosis before the patient has become conscious of any reduction of visual actify or limitation of the visual field by tonometry and scotometry in at least 28% of the cases

(3) that 30% of the cases came with symptoms of eye strain believing a change of glasses to be necessary

(4) that the present day tendency for people to consult optometrists as a result of their aggresive propaganda is a bar to the early recognition and diagnosis of simple glaucoma

In conclusion it seems fair to say from the study of the cases reviewed and from the generally expressed opinious to be found in the literature that the most important single procedure in the diagnosis of simple chronic glaticoma is tonometry. If, as already has been stated, all the symptoms and signs of glaucoma depend upon increased intra ocular tension we must agree with Hiden that, "it is incumbent upon us to discover its presence before the symptoms occur."

DISCUSSION

Dr Arthur Bedell—It is a great pleasure to discuss Dr Marlow spaper. He has so carefully analyzed the many complex problems associated with the drignosis of this disease that it seems wise for me to confine my remarks to the changes in the fundus dwelling for a moment upon the variations in the disc structure which may lead to inaccurate drignoses and then presenting photographs to illustrate the actual disc appearance as found in cases of proven simple glancoma.

The critical inspection of these photographs should convince the skeptical that there is no method so dependable or so accurate as stereoscopic photography and it will further show that small shallow central excavations are found in cases with high intraocular tension and that large deep excavations are seen when no glaticoma is demonstrable. The pictures also emphasize the lact that very extensive undernining of the disc may be found with only very slightly increased tension and furthermore this elevated tension may not be constant. We experience our greatest difficulty in distinguishing

between some types of simple glaucoma and optic

rtophy

To give point to these observations, a group of photographs have been selected for a lantern slide demonstration. These melude several normal eveavations, anomalions exit and entrance of vessels, temporal comis, crescent staphylomi circumpapillary atrophy and optic nerve atrophy. Special emphasis is placed upon the great difference in appearance in the disc in simple glaucoma. This ranges from an extremely small, shallow central excavation to the complete undermining cup. The importance of carefully focusing the true disc margin is illustrated and discussed. The use of red free light is referred to as a valuable and in distinguishing between nerve lissue and scleral exposure.

To make the diagnosis of simple glaucoma from the funding examination the ophthalmologist must be alert and able to recognize the physiological variations as well as distinguish between primary atrophy and the second ary destruction of nerve fibers

John M. Leans New York, N. Y.—I wish to discuss but one phase of Dr. Marlow's paper—namely the visual fields. The return is not uniformly sensitive to light over its entire extent. When various sizes of objects are used we are able to determine the thresholds of various retural zones of light sensitivity. By the use of small objects or by reduction in the general illumination we lower the entire retural response to a level at which it is easy for us to defect variations from the normal. It intales relatively little difference what the state of light adaption may be so long as the conditions are such that we can reproduce them.

It is thus apparent that properly conducted examinations of the visual field with reduced illumination or with relatively minute objects may be interpreted in terms of

a light sense test the diagnostic value of which is proven by the importance we have come to assign to visual field studies

In the past we have looked upon a scotoma as a two dimensional projection of a defect in that passively expectant photographic plate the return. There is much evidence lowever to show that returnal response is in a refund sense modified by the heart bear respiration virtuals and chi road metabolism and its own vital processes.

We are forced then to consider not only the surface dimensions of length and breadth as we have in the past but do the altitudinal dimension of depth we include not only the retina but also all its associated lissues. This forces the inclusion of the dimension time

THE PATHOLOGY OF CHRONIC SIMPLE GLAUCOMA

By ALGERNON B. REESE, M.D., NEW YORK, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

THE pathologic changes demonstrable in eyes affected by chronic simple glaucoma are consequent to an increase in the intra-ocular pressure. There is a functional or dynamic factor about which we know little antedating the rise in pressure and the resulting changes to be discussed in this paper. Therefore, this discussion necessarily deals with the lesions produced by glaucoma rather than the lesion producing glaucoma. The various sites of such lesions will be discussed.

Filtration Angle-Peripheral anterior synechia is a common finding. Some factor not well understood causes the apposition of the anterior surface of the iris in its periphery to the posterior surface of the cornea in the region of the pectinate ligament. If the apposition of these structures occurs often enough and over a sufficiently protracted period an agglutination of the surfaces takes place which in due time becomes a permanent adhesion which is termed a synechia. When this occurs over a sufficient degree of the circumference of the angle there is a constant increase in intra-ocular pressure which can only be relieved by the formation of a vicarious sluice way for filtration of the aqueous subconjunctivally. If the glaucomatous state is not relieved the peripheral synechiae increase in breadth. Therefore, it can be said that peripheral synechiae cause glaucoma and glaucoma causes peripheral synechiae. Here is a vicious circle which is initiated by the unknown factor in glaucoma. When the synechiae occur over a broad area it is possible in performing an iridectomy to allow the keratome to enter the posterior chamber instead of the anterior chamber and thus rupture the anterior hyaloid membrane which results in the loss of vitreous. Also, when a trephine operation is performed on such eyes the trephine may go through the synechiae into the posterior chamber with a similar injury to the anterior hyaloid membrane. Obviously if the trephine opening goes through the synechiae the iris can not prolapse for excision. When a cyclo-dialysis is performed in the presence of broad synechiæ the tendency is for the spatula to perforate the iris because the radius of curvature of the sclera is greater than that of the cornea.

Cornea—Normally, fluid can pass through the cornea from the conjunctival side to the anterior chamber but not in the reverse direction. When the intra-ocular pressure is elevated, this fluid is forced into the cornea from the anterior chamber and the changes seen in the cornea in glaucoma are mostly incident to this. The steamy appearance seen clinically is based somewhat on edema of the

stroma but this is not the entire cause, for witness its immediate disappearance when the pressure is reduced by evacuation of the anterior chamber. It is therefore supposed that a large factor is the distortion of the corneal lamellae by the pressure which changes their refractive index. The stippling of the corneal epithelium is due to separation of the individual epithelial cells by edema which thereby breaks their continuity and thus decreases the lustre of the surface. Not only is there a separation of the individual epithelial cells but also a tendency toward a separation of these cells from the underlying Bowman's membrane. In glaucoma this weakening of the union of the epithelium to the membrane makes an abrasion more possible and particularly is this seen following the use of a tenometer if some care is not exercised against it. The separation of the epithelium from Bowman's membrane may occur spontaneously by the accumulation of fluid between the two and is termed a vesicular keratitis. If this vesicle ruptures the resulting filaments of redundant epithelium give a condition termed filiform keratitis. In the later stages of glaucoma there is a tendency for the ingrowth of a thin fibrous membrane between the epithelium and Bowman's membrane termed a pannus degenerativus. When this occurs from the limbus into the periphery of the cornea it usually carries with it some capillaries. There is normally a slight physiologic pannus in the periphery of the cornea above and it is over this site where the glaucomatous pannus usually extends farthest. fact often makes it easier to dissect the epithelium from the corneal lamellae in performing a trephine operation. When a glaucomatous pannus appears in the cornea other than at the limbus it is usually in the nature of disseminated faint irregular grayish white areas which in time may enlarge and conflue. These represent very thin, non-vascular plaques of fibrous tissue which extend through the nerve canals of Bowman's membrane to spread out under the epithelium. If they conflue and then are separated by fluid from the membrane along with the overlying epithelium they form the condition known as bullous keratitis. A deposit of pigment granules on the posterior surface of the cornea is an early and frequent manifestation of glaucoma. The nature of these deposits will be discussed later.

Iris—The earliest organic change demonstrable in a glaucomatous eye is the dispersement of pigment which is mostly seen in the iris with secondary deposits on the cornea and in the meshes of the pectinate ligament. Pigment globules are seen migrating through the stroma of the iris towards the anterior surface and thus into the

anterior chamber. This pigment comes in part from the pigment epithelium on the posterior surface and in part from the chromatophores of the stroma.

Attophy of the tris is a frequent finding in glancomatous eyes. It may be of two types both of which may be present in the same iris. For purposes of description these types will be designated as atrophy with proliferation of the stroma and atrophy without proliferation of the stroma

I Atrophy with proliferation of the stroma This is by far the commoner type the iris has a bleached gray appearance, the surface markings such as the crypts, the contraction furrows and the angular line are missing in part If it is of sufficient degree and dura or wholly tion the pupil will be immobile and in mid-dilatation or larger and usually an ectropion uvea of varying degree will be present. Microscopically, we find that the delicately branching loosely arranged chromatophores of the stroma have been replaced by a denser, parallel coursing fibroblastic In other words the iris stroma has been replaced by a non pigmented fibrous membrane This explains its acquired color and the loss of the surface markings The fibrous membrane has no clasticity and thus splints the iris and renders it The contracture of the fibrous tissue ımmobile tends to cause a gradual dilatation of the pupil As the pigment epithelium takes no part in this contracture it extends around the pupillary margin onto the anterior surface of the iris producing the ectropion uvea.

2 Atrophy without proliferation of the stroma Clinically, this is seen as rarefied areas of the stroma or even complete disappearance of the stroma at which sites the black pigment epithelium shows through in bold relief. In an extreme degree one sees a hole through the entire iris

The cause of atrophy of the iris

The pressure in the veins of the iris is about 30 35 mm of Hg and that in the arteries about 60 70 mm of Hg When the intra ocular pressure reaches that of the veins of the iris there is some passive congestion which results in an ef fusion of some fluid in the interstices of the This causes pressure on the delicate chromatophores and results in some pressure necrosis Pigment is thus liberated some of which is absorbed and some dispersed. Chromatophores can not reproduce chromatophores therefore the reparation of those destroyed is by fibroblasts Thus the atrophy of the iris with proliferation of If the intra ocular pressure reaches its stroma that of the arteries of the ins then an ischaeinic necrosis occurs which results in the disappearance of the stroma and thus atrophy of the iris with out proliferation of its stroma. The reason that an ischaemic necrosis of the iris stroma does not always occur in eyes with an intra ocular pressure of 60 70 mm of Hg is due to a vascular compen

sation which occurs when the intra-ocular pressure gradually reaches such a degree over a long period. It is thought to appear only in those eyes in which a sufficient time has not elapsed for a gradual vascular compensation before such a high degree of intra ocular pressure ensues. Also, the state of the blood pressure in the individual may be a factor.

Optic Nerve-In very young people (up to the age of approximately 12 years) glaucoma causes an increase in size of the entire globe (hydrophthalmos and buplithalmos) whereas in adults it causes a giving at some vulnerable place the most pronounced of which is over the site of the foramen opticum sclerae which is protected only by the lamina cribrosa If the intra ocular pres sure is increased very slightly over a long period the lamma cribrosa will manifest a resisting re-Usually, tho, the inaetion by proliferation tra ocular pressure is sufficient to cause the lamina to give, which results in a cupping of the disc When a cupping of the disc occurs it is permanent The cup may become filled, tho, and thereby ostensibly disappear in two ways. The fine ghal meniscus which covers the surface of the normal disc may proliferate and completely fill the cup Also, when the increased intra ocular pressure is suddenly reduced to zero by an operation which evacuates the anterior chamber an effusion of fluid occurs in the intra ocular tissues One of the sites where the edema is particularly marked is often the disc It so happens, therefore, that following an operation occasionally the cupping of the disc will disappear to reappear again as soon as the papilloedema disappears

Exactly how the pressure around the optic disc destroys some of the nerve fibers and thereby gives the various field defects is not entirely understood The nerve fibers which are the axones for the neurons immediately around the disc un questionably he deepest in the nerve fiber layer as it courses around the periphery of the foramen opticum chorioidae and sclerae to form the optic nerve Increased intra ocular pressure, therefore, presses these fibers against the border of the foramen opticum chorioidae and sclerae and is therefore probably the cause of the field defects around the blind spot (Bjerrum and Seidel Scotoma) The cause of the constriction of the peripheral fields which occurs particularly on the nasal side is difficult to say The nerve fibers from the periphery of the retina he most superficial at the periphery of the disc. They are therefore not pressed particularly against the borders of the foramen The explanation of the peripheral field contraction is probably based on arterial compression at the disc which manifests itself in a nutri tional disturbance at the periphery of these end The fact that there is a greater distance traversed by the retinal vessels from the disc to the periphery of the retina on the temporal side

than on the nasal side is some substantiation.

In the optic nerves of eyes affected by glaucoma one not infrequently finds flat cavernous spaces. They occur in the intra-lamina part and run parallel to the surface of the lamina cribrosa. They are usually called Schnabel spaces as he gave a particular interpretation to them. He claimed that they were evidence of a primary atrophy of the optic nerve and that the cupping of the nerve appeared as a result of the collapse of the spaces. This served to explain those cases classified as simple glaucoma in which no rise of intra-ocular pressure can be detected but in which a cupping of the nerve and field defects are present. Belonging to this same group are those interesting cases described by Arnold Knapp in which sclerotic changes of the basal vessels of the brain cause a pressure on the optic tracts sufficiently to produce an atrophy of the optic nerves and then slight cupping and field defects simulating simple glaucoma.

In glaucomatous eyes pressure around the optic nerve sometimes causes atrophy of the pigment epithelium adjacent to the disc and thereby gives an ophthalmoscopic picture of a somewhat bleached area around the disc usually termed the glaucomatous halo.

In a recent monograph on "Glaucoma and the Retinal Circulation" Salzmann has shown conclusively that glaucoma frequently causes an occlusion of the central retinal vein. He describes four factors which are at work constantly in glaucomatous eyes tending to narrow the central vein gradually but progressively. At any time during this process of narrowing an acute occlusion may occur by the formation of a thrombous and thus hemorrhagic glaucoma. If, however, the process suffers no intercurrent thrombosis but proceeds

progressively to complete occlusion of the vein then sufficient time elapses for the formation of collateral circulations. These take place from the veins of the disc into the chorioid or into the veins of the lamina cribrosa and then into the veins of the optic nerve sheath and by other routes. The collateral circulation may be sufficient to prevent any hemorrhages of the retina even in the presence of a complete occlusion of the central vein. It is a well known fact that a primary occlusion of the central vein often causes glaucoma therefore as glaucoma causes an occlusion of the central vein a vicious circle is established. The primary initiating force in glaucoma, which may be very insignificant, gathers momentum as it travels in the path of this vicious circle. When glaucomatous eyes have been quiet for years and suddenly show a high rise in intra-ocular pressure with resulting compensation disturbances it often means an occluded central As Salzmann says—the final act in the tragedy of glaucoma is frequently introduced by an occlusion of the central vein.

Retina—In the late stages of glaucoma cysts sometimes form in the retina and particularly in the macula region. These have been described clinically by Vogt who designates them as "honeycomb cysts of the macular." They are probably the result of venous stasis.

In the very late stages of glaucoma one notes a disappearance of the nuclear elements of the retina so that ultimately the retina may be reduced to merely its supporting tissue. In such instances one sees only a glial membrane instead of the retina,—a condition called gliosis of the retina. This is caused by a pressure atrophy of the rods and cones which initiates an ascending atrophy of the succeeding neurones and their nucleii.

DISCUSSION

Bernard Samuels, M.D.: One of the characteristic and puzzling traits of glaucoma is the periodicity of the attacks, one attack being separated from another by comparatively free or absolutely free intervals. How it is possible, with pathologic changes that are continuously present, to have intermissions in the signs and symptoms of the disease, is not easily explained. There is certainly a factor in the pathology of glaucoma, as the essayist has intimated, which is not demonstrated in anatomic

preparations.

The pathonomonic sign of chronie simple glaucoma under the microscope, is the adhesion of the root of the iris to the pectinate ligament. Certain types of eyes are predisposed to glaucoma. Many eyes afflicted with glaucoma have a cornea small in comparison with the rest of the globe, and a shallow anterior chamber. There are wide variations in the thickness and texture of the iris. In some eyes it is thin, in others it is thick. In some anatonic preparations the root of the iris tapers off almost to a point at its insertion in the anterior surface of the ciliary body. In other preparations the periphery is thick and ends bluntly. A thin root of the iris is associated with a large well-rounded open sulcus, and the reverse is true when the root of the iris is thick. In hyperopic eyes the ciliary process often projects far under the periphery of the iris and are usually in close proximity to its posterior surface,

. It is known that glaucomatous eyes are mostly hyperopic, and that myopic eyes are seldom afflicted. It is true that eyes with anterior chambers of normal central depth are occasionally attacked with glaucoma, but under

the microscope these eyes may reveal narrow angles. We know that glaucoma is a disease of middle and later life and that it becomes relatively more frequent with each decade of life. With age the lens increases in size so that its anterior pole and with it the iris advances nearer and nearer to the cornea. We cannot see what is happening at the angles clinically, but anatomic experience teaches that all glaucomatous eyes, with few exceptions, show under the microscope adhesions at the

In regard to the dependance of glaucoma on diseases of the body as a whole, such as diabetes, albuminuria, and hypertension, it is striking that glaucoma does not occur oftener in systemic diseases. It is remarkable that it occurs so often in individuals who are in good general health although they may complain of nervousness. The cause and pathology of chronic simple glaucoma are to be sought rather within the globe than without.

Harold II. Joy, M.D., Syracuse, N. Y.: Dr. Reese has presented a most interesting demonstration of the pathology of chronic simple glaueoma, and it has been ably discussed by Dr. Samuels. My remarks will be eon-

fined to some phases of its pathogenesis. I do this with the realization that much of it is controversial.

With our present knowledge, we must as Dr. Reese has stated, attribute most of our pathological changes to an increase in intra-ocular tension. And yet there must be other factors, for glaucoma simplex is a disease of which hypertony is only a symptom. It is a disease which is a part of a systemic disturbance closely related to vascular changes and nerve influence.

As a result of the vascular changes and disturbed nerve innervation, there is capillary instability and increased permeability causing an alteration of osmotic equilibrium. As a consequence, we have ocular edema, which together with the embarrassed capillary circulation, the angio-spasm, the selerosis of vessels and stroma, impair the tissue nutrition, and undoubtedly produce pathologic changes aside from the resultant increased ocular pres-This affects all the intra-ocular tissues, but the optic nerve would seem to be particularly vulnerable. This may explain the optic atrophy in such conditions as VonGraef's amaurosis with excavation, as well as those cases of simple glaucoma which go on to blindness in

spite of early operation and subsequent normal tension.
Considerable experimental work has been done and various theories evolved to explain the field changes in glaucoma. The most generally accepted explanation is that of pressure on the nerve fibres. Traquair disagrees, maintaining that it is pressure on the blood vessels at the disc which causes these changes, at least in the early stages. From his perimetric studies he concludes that it is the anatomical condition of the disc which determines the order in which the fibre groups are affected. In most cases, the first fibres involved are those entering

the dise to the outer side of its upper and lower poles in the neighborhood of the large vessels. He maintains that if arcuate scotomata were due to pressure on the nerve fibres at the scleral ring, the defect would have to start at the blind spot and gradually work toward the periphery. As a matter of fact this is not always so. It may start peripherally and work in the opposite direction, and furthermore the most intensive part of the sectoms is not always that nearest the blind spot. Also, in the temporal field the defect is mainly peripheral from the first, and extensions from the disc are rare. Finally, the last part of the field to be lost is often close to the outer side of the blind spot with which it may remain in contact until very late. He explains the presence of an isolated scotoma by assuming that an arterial twig supplying that area has become occluded or stretched at the dise margins. This vascular theory is strengthened upon considering the character of the scotomata, especially in the early stages. They are sharply demarked, the acuity on either side being almost normal. This indicates a marked impairment of a small group of fibres rather than partial impairment of a consider-able number. It is what would be expected if there were interference with the vascular supply to that area. Magitot agrees that these changes are angioscotomas, and in addition maintains that arteriolar spasm is an important factor. He thus attempts to explain these sectomata which change in shape and size from day to day irrespective of the intra-ocular tension. He also cites a case reported by Gallois, who, in a patient with double glaucoma, injected acetyleholine (a vasodilator). In spite of an increasing tension the field progressively enlarged.

OPERATIVE TREATMENT OF CHRONIC GLAUCOMA

Report of 200 Successive Operations

By ARNOLD KNAPP, M.D., NEW YORK, N. Y.

Read at the Annuat Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

NE of the greatest advances in Ophthalmology during the last thirty years has been the sclerectomy form of operation for chronic glaucoma. Its advantages are now generally conceded, though the exact type of operation has not been agreed upon.

A consideration of this phase of the glaucoma question is best served by a presentation of a single operator's experience. For this reason I have selected 200 successive cases from my private records during the past twenty years, and their subsequent course was noted in as many of them as possible. The operations practiced were the Lagrange, trephining, iridectomy, cyclodialysis and irido-

tasis. (Table I.)

There were 95 Lagrange operations with 85 successes. In 10 cases, the filtration was not re-established and tension returned. Of these 10, in 2, trephining was then successfully practiced, and in 1, cyclodialysis, but without permanent result.

There were 80 cases of trephining of which 60 were successful; in 20 increased tension returned. Of these, a second trephining was performed in 9 which was successful in 7 and failed in 2; a cyclodialysis was done in 4, with 4 failures.

Iridectomy was attempted in 12 cases. In these, the tension was permanently reduced in 5, and in 7 it recurred: In 2 of these 7, trephining was done successfully in 1 and failed in 1.

There were 8 cases of cyclodialysis in which

⁺Filtration.

⁻Return of tension.

the operation succeeded in reducing the tension in 5, and failed in 3.

Iridotasis was performed in 5 cases. In all of

these the tension remained down.

In considering the unusually good results after the Lagrange operation it must be remembered that the cases were selected. This operation was done only when the glaucomatous process had not lasted for a long time, where the field was still good, the iris of good texture, and where the tension could be brought down with miotics to below 35 Schiotz. The cases which did not fulfil these requirements were subjected to a trephining operation. An iridectomy was done in cases seen very early, and where the tension could be readily brought down with drops, so that an obliteration of the iris angle was not present. Cyclodialysis was made in cases where there were reasons for not doing the other operations, such as nervousness on the part of the patient, myopia, or extreme advance of the glaucoma. Iridotasis was done as this operation had been so highly spoken of, and the tension was reduced in the few cases in which it was tried.

The Lagrange operation requires considerable practice, and the small Graefe knife must be sharp-pointed and firm. I have used with great satisfaction a small Smith-Wilson knife, which was made for me by Down Brothers, London. I have always found the special Lagrange scissors more satisfactory than the punch forceps. the Lagrange operation the anterior chamber generally restores earlier, and the pupil dilates better than after trephining, and the resulting filtrating area is smaller and presents a better protecting conjunctival covering than in many of the trephined cases. It is difficult always to get a scleral flap or tongue of just the right size. If the flap is too small, the resulting opening or gap in the sclera is apt to close; on the other hand, if the flap is too long the resected portion is too distant from the limbus. In a certain proportion of Lagranges though there is no raised filtration area, the gap in the sclera is visible and the tension remains reduced.

John E. Weeks (Archives of Ophthalmology, vol. 49, p. 320, 1920) laid great emphasis on massage in the after treatment of a Lagrange operation to insure drainage, but I have not been able to convince myself, after faithful trial that I succeeded in converting a filtrating wound which was closing, into an open one.

In a number of cases I tried the modified Lagrange operation which consists in reflecting down a conjunctival flap making a keratome incision, and using the punch forceps for the scleral resection, but the wounds had a great tendency to close than in the usual operation.

Failure in 25% after trephining corresponds very closely with European statistics.

There is very little\to add on the technic

of trephining, especially after Elliot's recent article in the Archives of Ophthalmology, vol. 8, p. 798, 1932, except to repeat that trephining is not as simple a procedure as it is made out to be. There is no operation on which one is so dependent on absolute sharpness of the instruments, and sharpening of a trephine is a difficult art. Then in the dissection down of the episcleral tissues, the eyeball sometimes becomes soft due presumably to opening the episcleral vessels, which makes the trephining of the sclera difficult and leads to the early escape of the aqueous with failure of the iris accommodatingly to pro-The attempt then to fish for the iris in unruly patients, leads to a traumatic cataract, which occurred in 2 of my cases. It is better to wait for 24 to 48 hours when the iris will be presenting in the disc area, and then can be seized and abscised after reflection of the conjunctival The Green modification of trephining (Archives of Ophthalmology, vol. 6, p. 752, 1931) was practiced in a number of cases with satisfaction, the filtration was moderate though adequate and the advice not to draw on the iris in making the buttonhole iridectomy was carefully A thin vesicular bleb cannot be avoided after some trephinings, and the dreaded late infection occurred in 3 of my cases. In 2 of these the eyes were lost from purulent iridocyclitis, and 1 recovered after treatment (milk and subconjunctival cyanide injections). cases the blebs ruptured spontaneously, fortunately the condition was remedied in time by a conjunctival plastic operation. It is generally believed that if a trepline opening remains open for a certain length of time, the opening is permanent. In one case which was under constant supervision, the trephine opening closed after 11 years with return of the glaucoma, requiring another trephining operation. The prognosis of secondary trephinings is much poorer than in the case of a primary operation, and the more dissection is done, especially in scar tissue, the less likely does filtration result.

The iridectomies were principally done at a time before the necessity of a scleral resection was generally accepted. In the last 100 cases only sclerectomies were done.

Cyclodialysis is a temptingly simple operation but the results have been very disappointing, principally because one never knows how long the good result may last, and another serious objection is, that the return of tension may be abrupt and stormy.

Iridotasis was not persisted in because in 2 of the cases, large, thin cystic scars developed partly composed of iris tissue.

Every one knows that the results of operations for chronic glaucoma depend greatly on the type of eye affected. A difficult type is the very hypermetropic, rudimentary eye with an unusually shallow anterior chamber; operations in these cases usually do not establish drainage and the anterior chamber remains shallow. The prognosis is bad, though extraction of the lens

may be attempted.

There were 14 cases in which though sufficient filtration had been established, the vision and particularly the field underwent a progressive deterioration. This is a very striking feature which is difficult to explain, though it has been repeatedly mentioned in the literature.

While investigations of glaucoma and its

causes are undoubtedly making progress and should be encouraged in every possible way, valuable time must not be lost in experimenting with medical treatment, and the favorable time for successful operation must not be allowed to pass. There are undoubtedly several methods of operating in chronic glaucoma, by which a satisfactory result can be obtained, and I concur entirely with a quotation which I think was expressed by Dr. John E. Wecks, "that whatever method the operator can use with confidence is the best method for him."

DISCUSSION

must be taken to be sure that the posterior surface of the iris is entirely exposed, because in cases of partial prolapse a cyst of the iris is apt to form, leaving an unsightly lump. It is very easy even if the iris fails to prolapse, to pull the conjunctiva to the nasal side and, inserting an iris forceps, place the iris in the posi-tion required. Originally, I was satisfied with a simple suture of the conjunctiva wound, but the pressure of the aqueous in the early stages tend to make a rather tenuous scar. So, in my more recent cases, I have found that the matress suture carried under the temporal edge of the conjunctiva results in a more firmly closed

The beauty of this method of operation is that there is less trauma, speedier convalescence, and an almost

certain reduction of pressure.

I feel that massage is a valuable method of treatment following operation, but I also believe that it is generally wrongly applied. When done in the early generally wrongly applied. When done in the early stages of any operation, it should be performed standing back of the patient and massaging from below rather than from above. When massage is done from below, the pressure of the fingers tend to send the aqueous towards the operative wound. Whereas, if done from above the pressure would rather tend to close the original wound and force the fluid in the wrong direction. I have seen definite benefit from massage, and think it is a valuable method of treatment.

Dr. Arthur C. Bennett, M.D.: Having done about one hundred iridotasis operations, I can say, without

hesitation, that this method has given me the best all round results, and I have tried all the other methods that Dr. Knapp numerated in his paper. In this experience, I am backed up by Colonel Herbert of London and Dr. W. H. Wilder of Chicago.

I have recently employed a method that is slightly different from the classical iridotasis operation, but it has been so successful in my hands that I will, with the chairman's permission, demonstrate by diagrams the method I employ. Almost without exception this has been done under local anesthesia. I prefer to use a Wheeler's Discission Knife, entering the point at about half past one, at about 4 mm. external to the limbus. Directly the point is seen in the anterior chamber the handle of the knife is depressed to horizontal and the blade is advanced to a corresponding position, and emerging about 4 mm. or a corresponding point to the wound of entrance, being careful not to puncture the conjunctiva. The knife is now almost in the angle of the iris and by making a slow incision the aqueous will escape under the conjunctiva raising a watery bleb. If care is now taken the section can be completed without cutting the conjunctiva further, except at the wound of entrance. On the completion of the section the iris will nearly always be present in the wound, but care

MEDICAL TREATMENT OF CHRONIC SIMPLE GLAUCOMA By WILLIAM ZENTMAYER, M.D., PHILADELPHIA, PA.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

THE treatment of Chronic Simple Glaucoma is essentially surgical. Medical treatment is however indicated when operation is refused; in most cases in the early stage of the disease; in patients who acquire the disease very late in life, if the tension is not too high or if they are in poor physical condition; and in cases in which one eye has been operated upon with unfavorable results, and with greatly contracted fields in the

remaining eye. In 1895 Zentmayer and Posey studied 167 cases of Chronic Simple Glaucoma and concluded that the effect of the administration of eserine and of the performance of iridectomy in checking the course of the disease is proportionately the same. They advised therefore that miotics should be employed in all cases, but if at the end of a month the field had diminished, iridectomy should be performed.

Later Posey gave a fresh impetus to the use of miotics by publishing his results in their use in private practice. He showed that in early cases treated by eserine full vision with somewhat restricted fields might be present for from ten to twelve years; and that they were capable of preserving the central vision for a long time, and to a less extent the fields, of cases already advanced before miotics were employed.

It will be of interest and advantage to quote Dr. John E. Weeks on the use of miotics in the treatment of Chronic Simple Glaucoma. He says: "For many years I have made it a routine practice when time and circumstances permit to try the effect of miotics in all cases of hypertension before advising operation. There are a number of conditions that may develop which cause me to decide that operation is desirable, and when convinced that

operation is the conservative course to pursue I inform the patient that he must assume the responsibility for the consequences if the advice is not followed. A diminution in the field of vision for form and colors, with or without enlargement of the blind spot, is an urgent sign, as is also a slight positive diminution of vision. It is allowable to permit a low degree of hypertension if no falling off in the fields for form and colors, or diminution of vision can be detected. Operation is advised if the patient is inclined to irregularity in the use of the miotics, and in contemplated long absences from efficient observation by a competent ophthalmologist. Experience has convinced me that early operation is desirable."

Posey's views may be stated thus: Miotics should not be used where there is a doubt of the patient's cooperation in the persistence of the treatment or where the patient lives at such a distance from ophthalmic care that he is unable to report at sufficiently frequent intervals for the supervision necessary. In all patients under 55 an operation on the more affected eye should be performed and miotics used thereafter in both eyes. In all cases of chronic glaucoma without regard to age or the development of the disease, in which miotics have been given a faithful trial for at least six weeks or two months, as evidenced by constant maintenance of the pupil to almost pinpoint size, if the vision and fields show progressive deterioration operation should be performed.

As yet we have no way of knowing what the response of a given case of glaucoma will be to the medical treatment, or the reaction to a decompression operation. Many of us must have had the experience that using our best judgment we have operated on an eye for glaucoma with disastrous results. In consequence of this we have persisted with the medical treatment of the equally affected fellow eye, with the result of seeing the symptoms held in check for years.

The following case history illustrates this point: A man aged 68 years first came under observation with the upper field of each eye lost. He had no suspicion that there was anything seriously wrong with his eyes. Vision in each eye was 6/9. Tension, with the Schootz tonometer was 49 in the right eye and 36 in the left. Both discs were deeply cupped. A consultation was had and a trephine operation on the right eye was advised, and per-November 5th, 1929. apparently correctly performed and the eye did well for a time but after the lapse of several weeks a low grade uveitis developed, with high tension and bullous keratitis, requiring enucleation.

When first seen the left eye was affected to about the same degree as the right except for a higher tension. Because of the disastrous result of the operation on the right eye consent could not be obtained to operate upon the left eye. Pilocarpin, 1/4 gr. to 2 drams, was prescribed for instillation twice a day, and eserine of the same strength at bed time.

As the tension was not holding at the end of several months, ½ per cent eserine three times daily, with an adrenalin pack once a week, in addition, was necessary. time a severe folliculosis of the conjunctiva was set up, with haze and vascularity of the The eserine was discontinued and dependence placed upon gynergen and occasional adrenalin packs. These agents together with an astringent collyrium have now been in use since January 1932. Today after three and a half years since he was first seen, tension with the Schiotz tonometer is 25 mm Hg. on most occasions, and the field is unchanged. Visual acuity is slightly reduced probably because of the corneal condition.

If the aqueous humor is a dialysate of the blood plasma through the walls of the capillaries, and glaucoma results from some disturbance of this metabolism the medical treatment of glaucoma,—especially with the newer agents which act upon the capillaries,—should be of especial value. If the cause of glaucoma is to be sought in structural and mechanical interference at the angle of the anterior chamber with the outflow of the intraocular fluids, the main medical dependence in the earlier stages of the disease will be upon miotics.

It goes without saying that for miotics to be efficacious they must be properly administered. As the disease is a chronic one the action must be long maintained and for this reason the dose must be gradually increased, and as their action is transient they must be instilled at least three times a day. As the object is to keep the pupil contracted, a strength sufficient for this purpose must be constantly maintained. As in the early stages of the disease the action of the iris is unimpaired a very weak solution will often attain this end. While no hard and fast rule can be laid down, in a general way it may be stated that the weaker of the miotics, i. e. pilocarpin should first be used. An initial strength of ¼ gr. to the ounce may be expected to keep the pupil to pin-head The strength will probably have to be increased until a 4 gr. solution has been When the stronger solutions are reached several annoying effects are at times noted, brow-ache, twitching of the lids (spasm of the orbicularis), spastic (dynamic) myopia, irritation of the conjunctiva, and occasionally posterior synechia. Some of these annoyances

may be allayed by incorporation of cocaine in the solution, and by using a weaker solution during the day and a stronger solution at bed time. Follicular conjunctivitis is less likely to occur if the solution of the miotic drug is kept fresh and sterile by prescribing a small quantity at a time, one to two drams, and by the use of an astringent collyrium twice daily.

The newer drugs for reducing intraocular tension are now known to all of you and it is therefore unnecessary to speak in detail of

their origin and nature.

The most used of these is adrenalin (epinephrine) or its substitute glaucosan. It is generally agreed that adrenalin used as a pack in the manner suggested by Gradle obviates the danger of the systemic effect of the drug occasionally noted when given subconjunctivally, and that its hypotonic effect is but

little under that of glaucosan.

Gradle's method is to anesthetize the eye with butyn or holocaine and to tuck a small pledget of cotton saturated with three or four drops of adrenalin up under the upper lid into the cul-de-sac and allow it to remain four or five minutes. Its absorption produces a dilatation of the pupil. At first the pupil usually assumes an eccentrically oval shape and finally, in the absence of synechia, it becomes round. In most cases of Chronie Simple Glaucoma a fall of tension of from five to twenty millimetres occurs. The period over which this reduced tension would have continued cannot be stated from my own cases as miotics were used to control the mydriasis.

S. Gifford found that by using adrenalin after the method of Gradle no systemic effects resulted. He draws the following conclusions from the use of adrenalin in 100 eases of Chronic Simple Glaucoma, in which two developed severe acute glaucoma: Adrenalin, or glaucosan, is of definite value in Chronic Simple Glaucoma as an adjunct to other remedies. It is dangerous in eyes in an inflamed state and in eyes with damaged vessels. The danger of provoking acute glaucoma is due to mydriasis. This danger is even greater in simple glaucoma than previous reports have indicated and should be watched for. Mydriasis should be prevented or minimized by the free use of miotics before and after the use of adrenalin.

I have not used the stronger solution of

adrenalin introduced by John Green.

Osmotic therapy.—The intraocular tension can be lowered by producing a hypertonic state of the blood plasma which results in an absorption of fluids from the ocular tissues into the blood vessels.*

Cantonnet was the first to employ this method. Hertel, Weckers, Duke-Elder, and Garland have since used it with success. Hertel employs 150-200 cc of a 10 per cent solution of sodium chloride but others prefer smaller amounts, 35 to 50 cc; in higher concentration 30 per cent. The saline is usually given intravenously, slowly and uniformly. It may also be administered by mouth or rectum. It finds its chief application in acute glaucoma though it may be safely tried in any form of glaucoma.

Massage.-Massage should be regularly employed in the chronic simple type of glaucoma. Its value has not received due appreciation. Any means which improves the circulation of the fluids will tend to lower the hypertension. The eiliary body and the structure at the angle of the chamber are quite accessible for massage. (It may be applied either digitally

or by special apparatus.)

In applying digital massage the patient is directed to gently close the eye. The surgeon then places the index finger of each hand upon the closed lid, and makes alternate gentle pressure over the ciliary region, much as in palpating the ball in taking tension. Beginning with slow movements the speed may be increased. In addition the tip of the middle finger should be moved circularly over the ciliary region. These movements should be continued for about three minutes, and given on arising and before going to bed, and occasionally more often according to the effect obtained. surgeons also employ gentle tapping of the globe. The patient must be instructed in the personal application of massage.

Diet.—Levan and Joseph noted marked reduction of tension with a low diet, 300 grams of milk per diem for four days. Lacroix found milk and vegetable diet beneficial. Passerelli advised that the meals of glaucomatous patients be divided up as much as possible.

The Part Played by Disturbance in the General System. - LaGrange, Risley and others have contended that glaucoma usually occurs in individual, who are in poor health. In the words of Risley: "Glaucoma is a disease coming on at an age when wear and tear, harassing vicissitudes, misfortunes, exposure, overwork, and vicious living have sapped the phy-siologic foundations of life, when infections have found entrance into the organisms through the doorway of the epithelium; and when a variety of toxic and autointoxic, and other influences, have set up vascular and cardiovascular disease associated with nephritis, uveitis, high blood pressure & c."

And LaGrange says that in glaucoma the eye is not merely hypertonic but also a sclerosed dystrophic organ which shares its

Maddox has recently extelled the use of the high frequency current in reducing the intraocular tension, but warns against its use in luffamed eyes and those with vascular degeneration.

troubles with the rest of the body, a body in which renal and cardiac disease, the calculus and arthritic diatheses, and neuropathy play leading parts. The secretions of this organ are toxic and anisotonic whilst the channels of the excretions are blocked. Of course these are generalized statements and far from holding good in all cases.

According to Gifford there are two general conditions which seem to have an undoubted etiological relationship to chronic glaucoma. These are the so-called vasoneurotic diatheses and the related condition of bronchial asthma. Such patients have unstable vasomotor mechanism and usually have an unstable nervous system as shown by urticaria, tachycardia, flushing and angioneurotic edema.

Von Hipple was probably the first to suggest that a disturbance of the organs of internal secretion might be a causative factor.

Friedenberg intimates that many characteristics of glaucoma suggest the importance of the internal secretions in its causation. He states however that endocrine etiology does not imply treatment mainly by gland substance but calls for a better understanding of the management of endocrine disorders.

Imre believes that disturbance of the balance of the endocrine organs causes a lasting change in the intraocular pressure. He has treated his cases with mixed extracts of the deficient glands. In 31 cases treated 27 showed a close relationship. The effect of the organ secretion is a specific one. When the defective organ or organs are discovered an extract of their substance is administered and the tension becomes normal in some cases where miotics and operation have failed.

Kümmel considers that glaucoma is but part of a general systemic derangement, and all operations are merely palliative. He found a well marked increase of blood pressure and other indications of diseased cardiovascular renal symptoms in glaucoma.

DeSchweinitz feels that operations are far from the last word in the treatment. He says: "The very best therapeutic means which an elaborate study of metabolism can suggest, or the aid of an internist can devise, are called for in the treatment of glaucoma."

Carlotti gives the history of 26 cases of various types of glaucoma which seem to prove a relationship of syphilis to glaucoma. He states that others have maintained the role played by syphilis but that most authorities ignore it.

So much has been written pro and con as to the relation of increased blood pressure and arteriosclerosis to glaucoma that no review of the literature can well be made. Among the studies which seem to confirm the relationship Charlin's are frequently quoted. He finds that 90 per cent of cases of glaucoma showed general vascular disease.

It is claimed by some that at corresponding age periods there is usually a higher average blood pressure in glaucomatous patients than in non-glaucomatous subjects. I think Elliott voices the conservative opinion today when he says that there is no obvious causal relationship between arteriosclerosis, with the attendant rise of systemic pressure, and the onset of glaucoma.

All this leads up to the importance of an exhaustive study of the patient, not only of the cardiovascular symptoms but the renal and nervous system as well. A thorough metabolic study should be made. All exogenous and endogenous factors should be eliminated. A suitable diet should be prescribed. Alcohol and other stimulants should be used only with moderation. Regular hours of rest at night, and during the day, should be insisted upon. Repeated refractions should be made. Reading should not be interdicted but instructions should be given as to proper illumination, and as to the avoidance of poorly printed books and papers.

SUMMARY

In the medical treatment of glaucoma the main dependence is upon physostigmine (eserine) and pilocarpin. Adrenalin and its substitutes are of value as adjuvants to be employed principally to increase the efficacy of miotics.

Ergotamin (gynergen) given by mouth is of value as adjuvant and also may be substituted temporarily for the local treatment when folliculosis develops.

Massage aids in the reduction of tension by improving the circulation of the intraocular fluids.

Osmotic treatments may be employed before operation to reduce excessively high tension.

No specific therapy is indicated but systemic conditions should be treated. Physical and mental rest, and diet, are important.

Conclusions.—In conclusion I should like to emphasize that the great majority of cases of Chronic Simple Glaucoma sooner or later require operation. In carrying out the medical treatment it is essential that this should be kept in mind, and so soon as the treatment fails to hold the fields and tension, operation should be done, as delay not only results in further impairment of the vision but also imperils the success of the operation.

Discussion-Dr. Thos. H. Johnson, New York: Our practice is to use myotics in all cases of chronic simple glaucoma over a period of from a few days to several weeks to determine whether or not the tension can be controlled. If normal tension and fields can be maintained the myotics are continued. It is our custom to start with solutions of 1/2% to 2% pilocarpine, depending upon the tension present when first seen, using the drops from two to four times a day. If pilocarpine does not control the tension it is reinforced by 1/2% to 1/26 eserine given from one to three times a day. I have under my care at this time two patients with glaucoma treated with myotics that have been under observation for ten or more years without loss of vision or serious field defect. My feeling is that when pilocarpine does not control the tension, an operation should be performed, except where the patient is advanced in years. It must be remembered that intraocular pressure is not only destructive to the nerve head, but presses the iris against the cornea in the iris angle, producing anterior synechia which in turn raises the tension by retarding filtration. The results from surgical treatment in my experience have been best in eyes that have been operated when the tension has

not been above the low thirties. Cases that run along with a normal tension with an occasional jump on into the high thirties or forties are best treated by operation, as this occasional increase in pressure brings about an extension of the anterior synechia. Although it has been my practice to use myotics as long as the tension and changes in the visual fields could be controlled, I believe that more eyes would be saved if an operation were done in all cases as soon as a diagnosis of glaucoma has been established, except in cases of advanced age or where there has been extensive pathological and functional changes before the patient has presented himself for treatment. Where the visual fields have been reduced to within 10° to 20° of the fixation point, myotics are probably the treatment of choice. Such cases in my experience have not responded favorably to surgical treatment ment. Where the corneal microscope or gonioscope show extensive anterior synechia it is obvious that myotics can not be effective. The above apparatus, if more frequently used, might give us a better insight into the condition of the iris angle. However, the practical test is tonometry. If the tension is above the normal level, we know that the destructive process is going on.

Discussion-Walter S. Atkinson, Watertown: The lack of accurate knowledge regarding the exact etiology of glaucoma necessarily limits the medical treatment to various palliative measures of a rather empirical nature, Local treatment alone is generally conceded to be inadequate; and the use of the various local agents such as miotics, glaukosan, massage, etc., afford only temporary relief. Glaucoma surely must be considered as simply a symptom of a complex disorder, the pathology of which still remains obscure. As long as this obscurity remains, there will be a great diversity of opinion regarding the methods of treatment. Certainly no one form of treatment now used is applicable in all cases of any type of

Psychic disturbances may often precipitate an acute attack of glaucoma or so upset the metabolic equilibrium

of the eye under treatment that it is difficult to keep the disease under control. Some of the newer sedatives, particularly of the barbaturic acid group, assist greatly in producing the proper mental relaxation which favors the control of the disease.

In non-congestive glaucoma, where it progresses in spite of the medical treatment and where an operation is indicated, the decision to operate requires courage and often a battle with ones conscience.

Since von Gracfe introduced iridectomy for the relief of acute glaucoma, there have been greater improvements made in the surgical treatment of glaucoma than in the medical treatment. So with our present knowledge of glaucoma, there seem to be three main periods suited to medical treatment; before operation, after operation, and when operation is contra-indicated.

Discussion-Albert C. Snell: In our management of simple chronic glaucoma, even when we have considered the criteria which should guide us in our choice between continued general and local treatment or operation, as has been so clearly presented by Dr. Zentmayer, we shall en-counter many individual cases in which no general rule or set of rules of procedure can be followed. In such cases we must attempt to formulate an opinion based on our judgment whether the chances of further deterioration of vision favor continued treatment or operation, and which procedure is the more likely immediately, or in time, to be followed by a visual disaster. In some cases the balance of judgment lies between the probability of the patient's outlasting the approach of visual disaster or useful vision outlasting the patient.

As a guide to aid our choice of procedure I believe that we may generally accept the rule that a tension of 30 mm Schoitz continued for 3 to 6 weeks without a period of lower tension must be regarded as a dangerous state. This degree of tension and any further loss of visual acuity or contraction of field indicates that medical treatment will not succeed.

A range of tension between 25 and 30 mm is the zone of watchful waiting. Many of these cases may continue the medical treatment over many years without material change in vision. Individual cases again will vary, and again our guide to procedure depends largely on the maintenance or loss in vision.

Dr. de Schweinitz suggested that the additional instillation of myotics some time during the night was a help in controlling or reducing tension. I have followed this advice in many cases with sceming benefit.

In some cases medical treatment must be continued simply because the hazard of operation is far too great. In this category are those cases of advanced general debility, cases of marked optic atrophy, those with only small central fields and those with fields of Seidel characteristic.

Since the physics and physiology of normal intraocular pressure seem to be placed on a firm foundation by the recent experiments of R. Sonderman, who claims to have proved that intraocular pressure is directly related to the colloid content of the blood, the medical treatment of glaucoma simplex should be further advanced.

SYPHILIS OF THE LUNG

Report of Four Cases with Autopsy Findings

HAROLD COMONFORT DENMAN, M.D., BROOKLYN, N. Y.

From the medical service of Kings County Hospital, Brooklyn, N. Y

THE appearance of a patient having syphilis of the lungs upon the wards of Kings County Hospital, together with the statement about the same time by the pathologist of one of the largest hospitals of New York City, that he had seen only one case of this disease in the lungs among 20,000 autopsies, caused the writer to review more carefully syphilitic patients who were suffering from involvement of the lungs. condition is apparently more common than the above figures would indicate, as autopsies have been performed upon four patients at the Kings County Hospital having syphilis of the lungs during the past two years. A report of one of these patients has already been given in detail,1 the histories of the other three are as follows:

Case No. 1 L Mc G.; a colored male infant, two months old, was admitted to Kings County Hospital, April 4, 1932, because of a cough of two weeks duration, which was becoming progressively worse. The following history was obtained from the mother of the patient. The onset of the present condition dates from two weeks before hospitalization, with the appearance of a "head cold"; coryza, cough, loss of appetite and a slight temperature, the cough became more troublesome with time, and the child's general condition became worse, although not alarmingly so, until hospital care was advised.

The family history was not contributory, the parents had been married one and one-half years, and were apparently in good health. Venereal disease was denied. The labor was normal, the baby was breast fed, well and gaining until the onset of the present condition

Physical examination revealed a fairly well nourished colored male child, acutely ill, with a paroxysmal cough and a thin mucoid nasal discharge There was dullness in the left anterior chest in the second to the fourth interspaces near the sternum and bilateral medium moist rales at both bases posteriorly. A tentative diagnosis of broncho-pneumonia was made.

Nose and throat cultures were repeatedly negative for Loeffler's bacillus. The spinal fluid was bloody on two occasions, and on examination, showed globulin, reduced Benedict's solution, no increase in white blood cells and no organisms were seen nor found on culture. The blood examination showed, white blood cells 14,000; red blood cells 2,048,000; polymorphonuclear lucocytes 64 per cent, small mononuclear leucocytes 34 per cent, large mononuclear leucocytes 1 per cent; the hemoglobin was 40 per cent; achromia and polychromatophilia were present. The blood

Wassermann reaction was four plus, the spinal fluid negative.

Two days after admission the patient showed spastic extremities with a positive Kernig sign, the abdomen became distended, the spleen enlarged and easily palpable, and the condition grave. The evidence of meningeal irritation became more manifest and a deepening jaundice supervened to death, with a purulent ear and a bloody nasal discharge. The lung signs were those of consolidation of both bases posteriorly. It is a pleasure for the writer to acknowledge at this point, the cooperation and aid given by Dr. Richard Rendich, Roentgenologist, and Dr. William Hala, director of the pathological department of Kings County Hospital, and their staffs in the preparation of this paper.

The post mortem examination revealed a colored child six pounds in weight and twenty-two inches in height. The lungs were a peculiar light gray color; not adherent, the surfaces were smooth; on section, both lower lobes showed a well demarcated light grayish area, which was rather firm on section, non-crepitant and friable (Figure 1.) The upper lobes were a light gray color but crepitant throughout A few small

Fig. 1. Case 1.

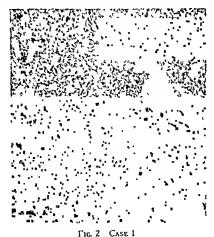

Congenital Syphilitic Pneumonia (Pneumonia Alba)

Fibrosis is well marked in the upper lobe at "A." In the
lower lobe at "A" the interstitual changes are more or
less obscured by a lobar consolidation.

petechial hemorrhages were noted on both lower pleural surfaces The head; on removal of the calvarium, a subaponeutotic hemorrhage was found in the parietal areas; the subpial vessels were congested.

Microscopical diagnosis was: brain; congestion and edema. The lungs; pneumonia alba, confluent broncho-pneumonia. (Figure 2) The

cause of death pneumonia alba

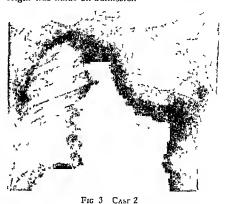

Congenital Pulmonary Syphilis 1002 Section taken from upper lobe of lung (figure 1) It shows the interstitual librosis so characteristic in cases of pneumonia alba

This is an example of the congenital form of s) philis of the lung-so-called white pneumonia -and the only type of pulmonary syphilis about which there is a general agreement. In this form of the disease gummata may occur, but as a rule are rarely seen. It is a diffuse fibroblastic proliferation with an interstitial infiltration of small round cells and is seen in still born babies, or those dying shortly after birth. The seeming well being of many of these infants at birth, and the negative history, is due, according to Warthin,2 to the apparent attenuation of the infection, especially in women, becoming so mild as to be practically nonexistant, an infection, perhaps not more active or injurious than the streptococcus of the mouth cavity. This type of lung syphilis may occur in the acquired form as a chronic interstitual pneumonitis or syphilitic pthisis. An example of acquired syphilis of the lung of this type was previously reported 1

Two types of lesion, the gumma and fibrosis are the chief conditions described by authors on this subject, although very different conceptions of these conditions exist among them Osler,*

and Lancereaux accepted these two main types Some authors denied the occurrence of pulmonary gumma, others described as many as seven types of this condition. But that the lesion occurs, is evidenced by the following case, of multiple gummata.

Case No. 2. O. C., a colored male, aged twenty-four years, single, was admitted to the medical service, Feb 10, 1932, complaining of a cough and loss of weight. The patient had not worked at his usual occupation of moving-van helper, for five months due to physical indisposition, but dates the onset of the present illness, two months prior to admission, when he first noticed a cough and weakness With time and the progression of the present illness, the cough became productive of a yellowish mucous never bloody or blood tinged He had night sweats, an irregular temperature, and lost thirty pounds in weight His appetite was good, and his bowels regular, not medicated The past history was not contributory. His mother, four sisters and one brother were alive and well, his father was unknown to On admission to the hospital he did the patient not look acutely ill, although the temperature was irregularly high and the pulse accelerated Physical examination revealed a fairly well nourished male negro There was no undue adenopathy The chest was poorly covered, with limited expansion of both sides, and presented the physical signs of pneumonia in the left lower lobe, with bilateral crackling rales in both upper lobes and broncho-vesicular breatling in the left apex. The heart was not enlarged and no murmurs were present. The blood pressure was 110/76 A diagnosis of pneumonia, probably of tuberculous origin was made on admission

Incamplete cansolidation of the left lower lobe, the consolidation being most marked in the mediol and upper portions of the lobe. The upper lobe and the right lung are well aerated and present no evidence of pathological changes.

X-ray examination revealed partial pneumonic consolidation of the left lower lobe. (Figure 3.) Repeated sputum examinations were negative for the tubercle bacillus. The urine showed a trace of albumen and a few granular casts. The blood examination revealed, 2,800,000 red blood cells, 17,200 white blood cells, 92 per cent polymor-phonuclear leucocytes and 8 per cent smaller mononuclear leucocytes. The blood Wasserman reaction was four plus.

The post mortem examination revealed a left lung entirely adherent to the pleura, especially the lower lobe. The weight was 1180 grams. On section the lower part of the left lower lobe was entirely caseous. In the middle section of this lobe, three well defined cavities were found, ranging in size from two centimeters to three and a half centimeters in diameter. The upper part of this lower lobe contained a strip of broncho-pneumonic infiltration and edema. The tissue in this latter part appeared filled with a gelatinous mucoid material, green in color. The upper lobe of the left lung was infiltrated with many miliary The right lung weighed 400 grams, and on section showed moderate compensatory emphysema and a few miliary tubercles.

The mediastinal and peribronchial glands were markedly enlarged (two centimeters in diameter) and on section were filled with caseous material. The spleen was normal in size, the capsule was smooth and of a dark slate color; on section the

pulp was soft and pultaceous.

Histological examination revealed—The liver: cloudy swelling, moderate passive congestion and gummata. The aorta: atherosclerosis and aortitis The spleen: chronic interstitial splenitis, moder-

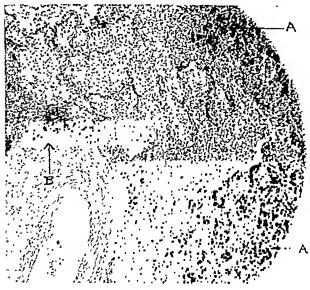

Fig. 4. Case 2.

Pulmonary Syphilis (Acquired). 80x. Observe the rather large areas of lobular consolidation at "A." The Pulmonary Syphilis (Acquired). cells in these areas consist of small lymphocytes and plasmatocytes. A small miliary gumma can be seen in the adventitia of the blood vessel. Arrow B points to it.

ate passive congestion and gummata. The lungs: numerous miliary gummata, (Figure 4) some rather large and showing central necrosis and secondary exudative inflammation, congestion, edema and moderate anthracosis. There was no evidence of tuberculosis. The cause of death was syphilis of the lungs, gummata of the liver and spleen and luetic aortitis.

Dann⁵ in 1908 first described pulmonary syphilis praecox; and many papers have since been written upon this from the clinical side, no autopsy studies have been discoverable to substantiate the early symptoms and x-ray findings of pulmonary conditions in the second stage of

syphilis thus described.

The following case is of interest, not that it throws light on the initial lesion of pulmonary syphilis, but in that the progress of this condition for seven months, to its fatal termination was followed by complete roentgenologic study.

Case No. 3. C. F.; a colored laborer, aged 42 years, was admitted to the medical service of Kings County Hospital on October 22, 1930, bccause of precordial pain. The following history was obtained from the patient; one year prior to admission he caught a "cold" producing a productive cough and slight dyspnoea which kept him in bed for seven months. Since that time the above complaints have become progressively worse, with the addition of precordial pain and the sensation of a swelling beneath the sternum on slight exertion. The sputum was in small amounts, white and never blood tinged. He also noticed progressive weakness, loss of weight and appetite.

The family history and previous personal history were not contributory. Venereal disease was denied.

Physical examination revealed an adult male negro, not acutely ill, dyspnoeic, nor in severe pain, with a slightly productive brassy cough. The eyes were bulging, their reactions normal. The chest showed retraction of the left supra clavicular space, and crackling rales on auscultation over the entire left side, anteriorly and posteriorly. The aortic arch was enlarged and the aortic second sound markedly accentuated, no cardiac murmurs were heard. Daily sputum examination for the tubercle bacillus were negative, cultures showed gram positive cocci in clusters, short chain streptococci, staphlococci and gram negative bacilli. The blood chemistry and blood count were normal. The blood Wassermann reaction was repeatedly negative.

Bronchoscopic examination October 22, 1930, showed an aneurysm of the aorta with narrowing of the forward cornua of the trachea preventing

passage of the instrument.

The x-ray examination of the heart and chest on admission, disclosed a moderate aneurismal dilitation of the ascending aorta with no evidence of pulmonary or pleural pathology. Further periodic study showed no change in this process until the fourth month of hospitalization, when a slight broncho-pneumonic infiltration of the left lower lobe was noted. Subsequent roentgenologic examinations showed a constant progression of the pathological process in the left lung, indicative of a chironic inflaminatory process, syphilis to be considered, and from a radiological point of view the lesion did not appear to be malignant (Figures 5 to 8). The patient died seven months after admission in marked orthopnea, having an

Evidence of moderate size aneurysm of the ascending arch, with almost complete absence of illimination of the inferior three-quorters of the left lung. Review of films show a constont progression of the pothological process in the left lung, which appears to be a chronic inflammotory affair—syphilis to be considered—and from a radiological standpoint the lesson does not oppear to be molinour.

almost constant brassy cough, fixation and left displacement of the trachea, difficulty in swallowing, pain not relieved by morphine, and the physical signs of absent aeration of the left lower lobe.

The post mortem findings were: the lungs were markedly adherent; there was no abnormal free fluid in the body cavities. The trachea, heart, lungs and thoracic aorta were removed en masse. The aorta bulged at its arch, and on opening the vessel, a sacculated aneurysm with blood clot acting as a valve was found. On removal of the clot, the coats of the aorta were found dissected. causing pressure on the lower portion of the trachea, and partial occlusion and displacement of the trachea to the left. The lungs were dark gray; their combined weight 1800 grams; the pleura was thickened. The left lung was adherent to the diaphragm. On section of the left lung, marked miliary tubercle formation was present, (Figure 9) and a purulent material exuded; at the base of the left lower lobe, bronchiectatic cavitation was found with an abundant fibrosis;

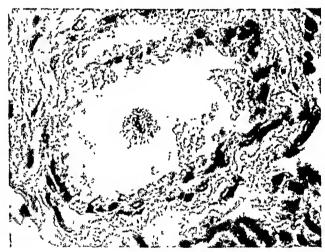

Fig. 9.

Pulmonary Syphilis (Acquired). 700x. A highly magnified picture of a pulmonary vessel showing the perivascular small round and plasma cell infiltration incident to lues.

the cavities varied in size from one centimeter to three centimeters in diameter. The right pleura was thickened, and the right lung on section showed raised granular areas, together with miliary tubercle formation.

The heart weighed 250 grams; the epicardial fat was present; on section the myocardium was fibrotic; the valves were grossly normal. The aorta in addition to the preceding findings, showed longitudinal striations of mother-of-pearl plaques. The coronaries were narrowed at the mouth of the vessels.

The histological data follows: the lungs, acute fibrinous pleuritis, chronic pleuritis, multiple pulmonary abscesses, broncho-pneumonia, definite luetic fibrosis, emphysema. The liver: chronic passive congestion. The spleen: chronic inter-

stitial splenitis. Kidneys: chronic vascular nephritis. The peribronchial lymph glands showed moderate anthracosis and hyperplastic lymphadenitis of luetic type. The aorta: luetic aortitis.

We do not know how often pulmonary syphilis occurs. It is indeed a very simple matter to determine the relative proportion of syphilities among the general population of a great city, as compared to the determination of the incidence of pulmonary syphilis among syphlitics. covery of pulmonary syphilis depends largely upon the personal experience of the clinician and the opinion of the pathologist; this may be influenced in a measure by the degree to which the subject has been popularized. The multiform variety of the lesions of syphilis of the lung as described by the early investigators, increased the difficulty of diagnosis, and may explain the wide differences of opinion as, expressed by them: Stolper⁶ described 61 cases of lung syphilis out of 2,995 cases, only one of which showed gumma, while Hunter gave the lungs the last place as the seat of syphilitic lesions. Carrera,8 while working in Madrid, in four years did not see a single case of lung syphilis out of hundreds of syphilitics. Rössle, however, described twenty-five cases of his own, and believed that syphilis of the lungs is at least as frequent as syphilis of the liver. Flockemann¹⁰ was of the opinion that, there is no good reason why the lungs should not be attacked by lues as frequently as any other part of the body.

Morgagni,11 whose knowledge of the gross pathology of syphilis consisted almost wholly of observations upon gummatous lesions of the bones, aneurysms of the aorta and change in the lungs and kidney, was of the opinion that the lungs were frequently injured by lues venerea. Rokitansky in his "Handbook of Pathological Anatomy," and Virchow in his "Cellular Pathology" added nothing to the pathology of syphilis. However, Virchow¹² in 1858 did distinguish the simple inflammatory from the gummatous lesions of syphilis, and showed for the first time the part played by this disease in producing inflammatory conditions of the most varied organs and tissues. Since the year 1797 many articles have appeared, mentioning syphilis of the lungs as a distinct affection, for there is no paucity of literature on the subject of pulmonary syphilis, nor dearth of figures relative to its frequency. Unfortunately, prior to 1900, the diagnosis of syphilis of the lungs made by many of these writers will not survive critical examination; tuberculosis, brown induration, chronic lymphangitis, gangrene and other lesions having been confused with luetic lesions. At Kings County Hospital, among 3,427 syphilitics, there were seventeen cases of syphilis of the respiratory tract, and of these, five were syphilis of the lungs, this diagnosis having been confirmed by autopsy in four. In the Bellevue Hospital series Symmers¹³ found syphilitic lesions of the respiratory tract in thirty-five of three hundred and fourteen cases, or 105 per cent, and the lungs were involved in twelve of the thirtyfive cases (38%) Warthin2 did not determine the percentage of lung syphilis in his series, but expressed the opinion that, our knowledge of syphilis of the lungs is very fragmentary and vigue

Differences of opinion have arisen in what constitutes pulmonary syphilis, and there is a lack of agreement as to the class of cases to be included under the title, syphilis of the lungs lum14 states that in the lungs "the lesions of the tertivry stage of syphilis, as elsewhere, are diffuse syphilitic infiltrations or gummata, but whether pneumonic or illcerative forms of syphilis with cavity formation really exist is uncertain" the recent writers admit the possibility of caseation of the gumma, and some of them, as Mar shall16 accept the possibility of its evacuation through the bronch: Stanley16 says that the first stages of lung syphilis are essentially those of an acute interstitial pneumonia In general the opinion of writers upon this subject is represented by Rossle' who says that the early stages of the lesion are unknown Warthin2 definitely states that "the gumina is not the essential typical lesion of old or latent syphilis. It is a relatively rare formation, and the great majority of cases of syphilis run their course without the formation of gummatous granulomata The new pathology of syphilis is based upon the demonstration that the essential tissue lesion of either late or latent syphilis, is an irritation of inflammatory process, usually mild in degree, characterized by lympho cytic and plasma cell infiltrations in the stroma,

particularly about the blood vessels and lymphatics, slight tissue proliferations, eventually fibro sis, and atrophy or degeneration of the parenchyma

There is no characteristic picture of pulmonary syphilis by the roentgen ray According to Jaches, 17 this diagnosis should be made only by the history, a positive Wassermann reaction, and the result of antisyphilitic treatment tunately, the Wassermann reaction is often negative with indubitable physical evidence of syphilis present. In the light of our present knowledge, Allison18 is of the opinion that even a tentative diagnosis of syphilis is not warranted until every other possible type of pulmonary disease is ex-The writer believes that in the presence of syphilis, and the evidence of a chronically progressive pulmonary infiltration, that syphilis of the lung, as a diagnosis, should be considered sec ond to none, and with Flockmann,10 that there is no good reason why the lungs should not be attacked by lues as frequently as any other part of the body It is not difficult to realize that the clinical picture of this condition is not character-The symptoms simulate pulmonary tuberculosis and the diagnosis of tuberculosis is usu-MacCallum's14 description of the ally made tertiary stage of syphilis and how difficult it is to differentiate it from tuberculosis, especially in the lungs, may be a good explanation for syphilis of the lung being so rare as an autopsy finding Yet, Carrera,8 in a study of sixty cases of tuberculosis, in comparing the connective tissue formation with that found in syphilitic lungs, was convinced that it is never impossible to distinguish the fibrosis of tuberculosis from that of syphilis

PROSPECTS FOR STATE MEDICINE

Walter Lippmann, writing in the New York Herald Tribune of December 14, said:

"I do not think it is possible to find an instance where a social order has been radically altered because some one thought some other kind of order would be better. There has to be a complete breakdown of the old order, a total paralysis, and an extinction of all hope that it can revive before a genuine social

revolution occurs. When these conditions do not exist, you may get a change of government, in moments of excitement, even a violent change, but when the smoke clears away, you are pretty sure to find the essential institutions and habits of the nation the same."

The family practice of medicine is still going strong, and the American people have no incentive to replace it with state medicine.

THE JOURNAL

This issue of December fifteenth of the New YORK STATE JOURNAL OF MEDICINE will be the last one to appear under the present Editorial Board. It is with a feeling of pride that we review the growth of the JOURNAL from the time of our taking charge ten years ago.

At that time it was very evident the Journal should play a more important part in the publicity of State Society activities. It was therefore reorganized and expanded, with a separate and complete staff, housed in its own quarters, and it has worked most effectively ever since as a har-

monious unit

We wish to thank our Executive Editor, Dr. Frank Overton, for his untiring devotion to an ideal; to Miss Bownc and Miss Wheeler for their enthusiastic support; to Dr. Stedman, an able

contributor and to Mr. Tufts, our Advertising Manager, whose time solely devoted to the Journal increased the advertising income over four hundred per cent during our tenure of office.

Unless this organization had been harmonious, loyal, and unselfish, the Journal could not have earried on during this last decade as a smooth

running department.

We wish to thank the Secretary's office, the heads of Committees, and those with whom the Journal has come in contact, for their cordial and sympathetic support.

To the new Editorial Board we wish the best success, and trust they will get the whole-hearted cooperation and support of the State Society. This they must have if the JOURNAL is to be a success.

ORNIN SAGE WIGHTMAN.

INDEX OF ACTIVITIES

For the sixth year this Journal is publishing a detailed index of the activities of the medical societies recorded in the Journal (page 1462). These records include those of the official medical societies of the counties and states, and of the nation. They have grown in scope and volume with the evolution and development of a spirit of cooperation among physicians, and now cover practically every phase of medical society activity. Of special value are the references to activities of other state societies along lines similar to those of New York State.

Experiences and precedents are of value in direct proportion to the availability of their Great movements often start from small beginnings, and their germs are found in a county society quite as often as in a state organization. In fact, it is a growing custom that a state society shall refer a new proposal to a county society for its trial and demonstration by a group of physicians who are in sympathy with the movement and will give it a fair trial. Graduate education, for instance, was first exemplified by county societies whose success encouraged the officials of the state societies to provide courses for the counties which desired them. The index of the graduate courses of the several states reveals a wide variation in the details of the courses: hut through all the divergence there runs a consistent plan of the promotion of the courses by state societies along lines which are adapted to the individual group of physicians. Anyone who is investigating the subject of graduate medical education will find the index of the activities recorded in this Journal to be a comprehensive guide to what is being done in that line by the official state medical societies throughout the entire nation.

The significance of events of history are not comprehended by those who are engaged in making the history. The evolution of every historie movement shows trials along many lines, some of which turn out to be practical, while others are visionary. There are medical leaders who discover new methods and new activities, only to find that they are already used successfully by some medical societies. On the other extreme are the doctors who kill every new proposition by references to its trial and failure in other societies. The journals of the medical societies of the several states carry a wealth of valuable records which are not available because they are not indexed in a central source. The annual index of the activities of medical societies contained in the NEW YORK STATE JOURNAL OF MEDICINE points the way to a wealth of experiences and precedents which will be of essential service to the officers and committeemen of the medical societies throughout the State.

An extensive index of the available records of the activities of a medical society is necessary if that society is to fulfill its mission of bringing all forms of medical service within the reach of every citizen.

MEDICAL PROGRESS

A Clinical Conception of Rheumatic Heart Disease.—After a critical analysis, Samuel A. Levine is of the opinion that it cannot be said that streptococci cause rheumatic heart disease. Similarly, the diligent search for and removal of foci of infection have proved far from effective in either preventing or ameliorating the ravages of the disease. A phase of the problem that has not received sufficient attention is the condition of the host or patient, the internal environment in which the disease develops, and especially the possible rôle the glands of internal secretion may be playing. The response of the human body to outside influences is very variable and difficult to predict. This is true whether the offending agent is a physical, chemical, or infectious cause, or whether it is a psychic trauma. Not only do human individuals differ from each other, but each one differs from year to year and from month to month in his bodily behavior, in physical, anatomical, and chemical make-up, and presumably in biological reactions to bacterial invasions. This is particularly true of the endocrine glands. It seems that many, if not all, are exposed to infection, certainly if the streptococci have much to do with it. One child gets the infection and manifests it as St. Vitus' dance, another polyarticular rheumatism, a third skin lesions, a fourth may show none of these lesions and respond purely with a pericarditis, etc. Furthermore, in the same person the internal environment may be in such a state that during one month or one year he may have chorea and at another rheumatism. It does not seem that such variations can be ascribed to changes in the infectious agent, but are more likely due to changes in the host. A striking observation in regard to chorea, which illustrates the author's thesis, is that one practically never sees chorea in patients over twenty years of age, except in a pregnant woman. Here pregnancy alters the internal environment, especially the endocrine balance. A further illustration is the occurrence of so-called "growing pains," which disappear as full growth and endocrine balance are established. Another peculiarity of rheumatic disease is its family incidence. While factors that spread the infection by contact are important, there must be an additional hereditary factor of vascular vulnerability. The following instance throws some light on this A husband and wife died of coronary artery disease. Among their children three developed hypertension in the thirties or early forties. Each of these children had one child with either rheumatic fever or chorea. There is reason to hope that an investigation of the glands of internal secretion will throw some light on the prevention and treatment of rheumatic heart disease.—American Heart Journal, October, 1933, ix, 1.

Thyroidectomy in the Treatment of Advanced Congestive Heart Failure and Angina Pectoris.—Samuel A. Levine, Elliott C. Cutler, and Eugene C. Eppinger refer to the remarkable results that have been obtained following subtotal thyroidectomy in patients with hyperthyroidism and various forms of heart disease. Those disturbances which are entirely due to hyperthyroidism may be permanently cured by surgical therapy. It has been discovered quite recently that hyperthyroid heart disease can exist with a normal metabolism and that even under such circumstances subtotal thyroidectomy can effect marked improvement of this circulation, even though it may not alter the metabolic rate. It would seem that not all the effects of the thyroid gland on the heart can be measured in the terms of basal metabolism. In order to test the possible application of these principles in cases of advanced cardiac failure but with normal glands, the authors performed partial or complete thyroidectomy on twelve patients—four with angina pectoris, four with valvular heart disease and auricular fibrillation, and four with non-valvular congestive heart failure. Only those suffering from hopeless, incurable, and intolerable heart diseases were chosen. Improvement in six was marked, in three it was slight to moderate, in one there was no improvement, and in one sufficient time had not elapsed to judge. One patient who was moribund at the time of operation died. The most promising group seemed to be those suffering from angina pectoris. From this brief experience it is impossible to predict whether the non-valvular or the valvular cases are likely to receive the most help. There were no conspicuous alterations in the blood flow or the blood cholesterol following operation in these cases. The authors feel that the results were sufficiently beneficial to warrant the conclusion that this new procedure will prove helpful in the treatment of properly selected patients suffering from various forms of heart disease who do not improve on the measures customarily used.—New England Journal of Medicine, October 5, 1933. ccix, 14.

Urticaria and Syncope "a Frigore."-Jean Affolter had occasion to observe in June, 1930, an unusual type of case in which brief exposure to cold water produced all the phenomena of a colloidoclastic shock. The patient, a young man in perfect health, had just begun to bathe in a lake when he observed a reddening of his limbs accompanied by a eurious sense of formication with intolerable itching, which soon extended over the entire surface of his body. The experience was entirely new. There was a strange metallie taste in his mouth, visual troubles appeared, objects assuming abnormal colors; his pulse beat violently, and it was with difficulty that he kept from losing consciousness. The phenomena lasted about half an hour. From that day on, they have reappeared whenever the patient has entered water at a temperature below 24°C. (75°F.), while exposure to cold air has no such effect. The author was able to provoke attacks in the subject at will, either by cold water or by spraying with sulphuric ether or ethylchloride. Immersion of the forearm in water at 18°C. (64°F.) sufficed to bring them on locally in two minutes, accompanied by an edema that stopped abruptly at the point where the contact with the water began. When a full bath was taken the entire surface of the skin was covered with urticarial spots, often confluent, which persisted half a day. Headache and diarrhea frequently accompanied the attacks. On one occasion when the temperature of the water was only 12°C. (54°F.), the patient actually collapsed, the pulse became imperceptible and he lost consciousness for half an hour. These attacks continue to the present day. A study of the white blood picture on these occasions shows a primary leucocytosis appearing almost immediately, followed by a fall in the number of polynuclears about half an hour later, after which a relative lymphocytosis and leucopenia of polynuclears appears. This leucopenia has the peculiarity of occurring after the urticarial eruption. From a study of the literature, three possible explanations suggest themselves: (1) That the disturbances were purely of vasomotor origin. (2) That there was a direct change in the tissues produced by the eold, such for example as a modification of proteins, analogous to what occurs under certain chemical influences or exposure to light rays.
(3) That an allergic process was in question, with a discharge of reagins. None of these possibilities can be absolutely rejected. Some of the phenomena cannot be accounted for unless both a vasoneurosis and an allergy are assumed. Recently E. Klein regarded these two mechanisms as opposed to one another. Affolter thinks, however, that this case is very instructive in this respect, and that the two processes may instead be combined.—Schweizerische medizinische Wochenschrift, September 9, 1933.

Theophyllin as a Diuretie,—C. Römer and H. A. Meyer say that, while the introduction of such mercuric preparations as salyrgan represented a gerat forward step in the dehydration of hydropic patients, they were attended with certain disadvantages, such as their injurious effects on the kidney and intestine, the production of too great a loss of water, with consequent weakness of circulation, not to mention the drawback of having to be given continually by injection. These authors have accordingly given their attention to theophyllin, a substance which was introduced into therapeutics in 1902, but which was relcgated more and more to oblivion because of its alleged secondary effects. They have been using it in the most various forms of hydrops, administering it in doses of 0.3 gm, t.i.d., combined with 0.05 gm. luminal, to offset its exeiting effects. A comparison of its diuretic properties with those of salyrgan shows that it is in no way inferior to the latter. It has a powerful diuretic effect in cardiac and renal affections, but in Laennec's cirrhosis of the liver, to the surprise of the authors, it has proved to be practically without any effect, which is in striking contrast with the powerful diuresis it sets up after a single dose of 0.03 gm. in ascites following cardiac insufficiency. The question arose, why this difference in effect should exist for theophyllin and not for salyrgan. It is known that salyrgan produces chiefly a sodium chloride diuresis, in which the water is carried along only in connection with excretion; also that mercuric preparations have a close relation to the liver. The effect of theophyllin, on the other hand, depends ehiefly on its stimulation of the cell protoplasm of the renal epithelium to inereased function, but it is probably also related to the secretory endothelium of the lymph eapillaries and canaliculi. In view of the ehanged activity and the dryness of the subeutaneous cellular tissue in cirrhosis of the liver, it may be assumed that these lymph capillaries and their endothelium constitute a poor point of attack here. Hence there is lacking the excitation of lymph excretion upon which the diuretic effect of theophyllin depends as much as it does upon the stimulation of the renal epithelium. This observation makes the administration of theophyllin an ideal means of diagnosis in cirrhosis of the liver, provided there is a well compensated circulation. Besides the simplicity of its administration, it can be given without injury for a period of many days. The extent of the diuresis it produces can be controlled better than that from salyrgan, and it has the advantage of being particularly well adapted for use in renal affections, in which the use of mercuric preparations is contraindicated.—Deutsche medizinische Wochenschrift, September 8, 1933.

Neurological Emergencies.—In dealing with the comparatively common crises in general practice, Wilfred Harris says it is possible to do good sound work with the ordinary neurological tools. Fits of various kinds are a common cause of difficulty, and a correct diagnosis will often mean the saving of a life. You receive an urgent call and find a middle-aged man, or woman, lying unconscious at the foot of a staircase. You have to consider whether the patient fell in a fit before going upstairs, or whether a severe fall downstairs has caused a fractured skull, or whether it is a primary case of cerebral hemorrhage. Evidence of bleeding from scalp or ear, or bruising, will indicate a fall, and further evidence of unequal pupils, conjugate deviation of the eyes, twitching of face or limbs, or signs of hemiplegia, may clinch the diagnosis of cerebral injury. An alcoholic smell may suggest drunkenness, but it is well to remember that a single glass of beer or cider taken two or three hours previously may taint the breath heavily. This is particularly important for police surgeons to remember with persons accused of being under the influence of alcohol to a degree rendering them incapable of driving a car. If the possibility of fracture of the skull has to be considered, an x-ray of the skull is important. there is a definite lump or gross irregularity of the skull, it is advisable not to wait for an xray, but to cut down on the bone to make certain of its condition, when a quick dealing with Concussion a depression may be life-saving. may be followed by recovery of consciousness, and later there may be delirium, increasing drowsiness, and coma. This indicates the on-set of cerebral edema. Lumbar puncture will almost certainly show yellow staining of the fluid from altered blood. If the pressure of the fluid registers 200 to 300 on the manometer, decompression must be done at once. Lumbar puncture will also settle the question of cerebral hemorrhage, but beware of withdrawing more than the minimum of bloodstained fluid, as the release of pressure may start fresh cerebral hemorrhage.

Before administering analgesics in severe headache, attempt to determine the cause, whether migraine or whether it is due to sinusitis, meningitis, cerebral tumor, or poliomyelitis. Exceeding violent and continuous pain in the region of the eyeball, termed by Harris ciliary neuralgia, may be relieved by alcohol injection of the Gasserian ganglion. Post-

herpetic neuralgia in old people is very difficult to treat. Morphine should be avoided and reliance placed on the milder sedatives. Gasserian injection is helpful in trigeminal Facial neuralgia may be relieved by the inhalation of trichlorethylene; glass capsules containing 10 minims may be carried by the patient and used when required. Vertigo in which objects swing is usually of labyrinthine origin, such as otosclerosis. The patient should be kept in a somewhat darkened room and given bromides, but not aspirin, salicylates, or quinine. A local blister or mustard leaf behind the ear may be of service. Harris has seen 50 cases of cerebellar thrombosis, which is characterized by urgent objective vertigo, intense nausea, probably vomiting, and intense feeling of malaise. The patient's position in space appears to him to be altered or even reversed. The treatment is rest and sedatives. In any case never take hope from your patient, it is often one of the finest remedies in or out of the pharmacopoeia.—The Lancet, October 14, 1933, ccxxv, 5746.

The Pathogenesis of Multiple Sclerosis: A Possible Vascular Factor.—Tracy J. Putnam states that there is no unanimity of opinion as to whether multiple sclerosis is infectious, neoplastic, toxic, hereditary, or degenerative in origin. The essential histological changes in the lesions were described by Charcot, in 1868, as consisting of a patchy loss of myelin, with relatively intact axis cylinders, perivascular infiltration, and dense glial proliferation. Nothing of importance has been added to this description. Experimental lesions have been produced by exposure to carbon monoxide, and by the injection of small amounts of tetanus antitoxin. Both of these methods are extremely uncertain. An attempt was made to determine what common denominator could exist between carbon monoxide poisoning, tetanus intoxication, and multiple sclerosis in human beings. Many possibilities were investigated and discarded, before it was recognized that in all instances the lesions had a predominantly perivascular distribution, as has long been recognized in multiple sclerosis, and in some of them actual thrombi could be demonstrated. The histological picture is different from that ordinarily seen, following thrombosis of a cerebral artery, which usually leads to destruction of axis cylinders, glia, and all nervous elements within the anemic area. In the plaques under discussion the lesion is a milder one. After further experimentation, and after reviewing his slides, Putnam came to the conclusion that when a lesion was definitely perivascular in location the central vessel could usually be identified as a vein, never as an artery. More recently he has been able to

produce some acute lesions, which have both gross and microscopic resemblance to those occurring in human beings, by injecting bland oily substances "upstream" into the longitudinal sinus of dogs. If the hypothesis that sclerotic plaques are due to venous obstruction can be maintained, most of the current conjectures concerning the etiology of the disease will have to be abandoned. The ultimate etiological factor should probably be sought in local vascular abnormality, or in some alteration in the coagulability of the blood.—
New England Journal of Medicine, October 19, 1933, ccix, 16.

The Cerebrospinal Fluid in Neurological Diagnosis.-In the Deutsche medizinische Wochenschrift of October 13, 1933, G. Wüllenweber points out the rather narrow limits within which the examination of the cerebrospinal fluid is of sufficient diagnostic value to justify the discomfort it causes the patient, which may persist even for months afterwards in some cases. In the last 10 years it has been taken almost for granted that to maintain the good reputation of a clinic the neurological patient should as a routine matter have his ccrcbrospinal fluid examined. This is a mistaken course: it should, instead, be the aim of every well schooled diagnostician to reach a neurological diagnosis without subjecting the patient to the unpleasant experience of a puncture. It does not help the experienced neurologist, when he has already established the presence of an intracerebral tumor with choked disk, to learn in addition that the pressure in the fluid is raised and the protein increased; nor is it of any interest to him whether or not, in a paretic with exalted ideas, the Wassermann reaction in the fluid is found positive. Wüllenweber would limit the use of the procedure to those cases in which the findings may serve to point the way to the right therapy through the correct diagnosis. The aim even then should be to withdraw as little of the fluid as possible. A careful choice should accordingly be made as to the type of examination desirable: whether its purpose shall be to establish the type of cells, the sugar content, the Wassermann reaction, or the amount and quality of proteins present. The three main types of cerebrospinal fluid findings may be schematized as (1) inflammation, (2) compression, and (3) degeneration, the pressure, cells, total proteins, and colloid reaction being, in each type of finding, more or less characteristic. In which cases, then, does examination of the fluid promise a successful diagnosis? (1) In those cases in which the question is raised, whether an organic nerve affection is present, in which event only the pathological outcome of the ex-

amination gives any dependable information. Here, for example, examination may reveal whether we are dealing with multiple sclerosis or with hysteria, with encephalitis or with a functional condition. (2) In those cases in which the question is raised, What organic nervous disease is present? Here examinations should be limited to those which may clear up the diagnosis. For example, the sugar determination alone is enough when it is a question between encephalitis and meningitis; the pressure determination alone, sometimes enough, for differential diagnosis between brain tumor and softening of the brain. Only the experienced physician is qualified to answer these questions, or to determine the amount of cerebrospinal fluid to be withdrawn.

Cancer, a Generalized Disease .- For a number of years A. de Coulon and A. Ugo have been looking for some method of defining in a numerical way what is meant by a normal organism, particularly with a view to defining cancer in such terms. To define the "soil" they availed themselves of a physicochemical property of albumins: namely, the iso-electric point, whether this be the muscular substance of the mouse, or in the blood serum of the human being, or of the rabbit. In a normal animal, a mouse for example, the iso-electric point is always found in the same zone of the scale of hydrogen ion concentration. It is the same in mice carrying grafter tumors as in mice with spontaneous or tar tumors. We thus see that the "soil" has been modified by the presence of a cancer, for the authors have confirmed the fact that this modification is not a result of the cancerous condition, but is one of its causes; that is, the soil has been modified by some cause, extraneous or otherwise, and only when its iso-electric point has reached a certain value in the hydrogen-ion concentration scale can a cancer appear. Thus, if the external ear of a rabbit is rubbed with tar, a small papilloma will appear after a certain lapse of time, at the site irritated by the tar. If the blood of these animals is regularly examined for its iso-electric point, during the entire time that they are being painted with tar, it will be observed that from the very early days this point has a tendency to rise in the scale, and that only when it has reached a certain value does a papilloma appear; then a more marked elevation precedes the transformation of this papilloma into cancer. It would thus appear that the tar influenced the entire organism, by so modifying the "soil" of the animal that its iso-electric point was maintained in a zone favorable for the appearance of cancer .-Schweizerische medizinische Wochenschrift, September 30, 1933.

LEGAL

VALIDITY OF CONTRACTS TO PROVIDE PROFESSIONAL SERVICES DURING LIFETIME

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

An interesting situation arose some years ago in one of our Mid-Western States, when the validity of a certain contract that a doctor had entered into was tested out in the appellate courts. The facts must be set forth at some length in order to understand the ruling.

A certain Dr. Z had been for a number of years engaged in the practice of medicine, and among his patients was an elderly lady of considerable wealth. She had been for some time a sufferer from various ailments including maladies of the heart, stomach and kidneys, and also a condition causing stiffness of the knee-joints, and a further condition referred to as a disease peculiar to her sex. A contract was prepared on her behalf and submitted to Dr. Z, which provided that the doctor should provide for her such medical attention as she would require during the remainder of her life, and in return the doctor was to be paid out of her estate upon her death, the sum of \$100,000 in ten equal annual installments. The doctor questioned the installment features of the agreement, and it was drawn up and executed with the provision that the entire sum of \$100,000 was to be paid upon the woman's death.

Over a year later the contract was re-executed, the sole modification being that a preamble was inserted stating that the older contract had been signed by the woman as "Mrs. J. H. M." and that to be sure of its validity the second contract was to be signed "Mrs. Harriet G. M." The contract was then executed in the said form, the essential portion thereof reading as follows:

"Mrs. Harriet G. M., does enter into an agreement and contract for the professional service to be rendered by the party of the second part, Z— M.D., at any time or place, during any spell of indisposition which I may be subjected to during the remainder of my natural lifetime; that in the event of sickness such methods are to be employed or adopted as seem best and most expedient; all medicines or other paraphernalia necessary to the discharge of duties in cases of indisposition are to be provided by Dr. Z—; that when the critical moment comes when it is thought that I may pass out Dr. Z—may call the physician or physicians as his judgment may dictate; that the sum which I voluntarily contract to pay for the services thus rendered is to be \$100,000 payable immediately or as soon as possible by my estate, which I leave in trust with the X— Trust and Savings Bank."

Subsequent to the execution of the said contract until Mrs. M died some three years later, the doctor attended her constantly, reserving for her a large portion of each day when he allowed

her to call upon him for attention to the exclusion of all other patients. When the woman removed her residence to a certain hotel, he also took quarters in the same hotel. When a few months before her death she went to California, the doctor accompanied her and remained in attendance upon her until she died. Repeatedly during the last years of her life, Mrs. M spoke to various people of how well satisfied she was with her agreement. Mrs. M was a well-educated and intelligent woman, and it was unquestioned that she was in full possession of her mental faculties up to the time of her death.

After the death of Mrs. M, Dr. Z filed a claim with the executor for the enforcement of the contract, and subsequently brought suit against the estate to enforce the claim. A bitterly fought lawsuit ensued which was carried to the highest court of the State before the doctor finally prevailed.

There was no attempt made, when the case was considered in the final appeal, to defeat the claim on the often urged grounds of fraud, undue influence, or insanity to invalidate the agreement; but the principal contention was that the contract was contrary to public policy. The court discussed this point as follows:

"It is urged that this contract is void chiefly for the reason that it furnished an incentive to the appellant to shorten the life of Mrs. M— by neglect or improper treatment or by commission of the crime of murder. Each argument made by appellee in support of this contention involves a breach of contract and is not founded on the performance of it. It cannot be seriously contended but that in order to comply with the terms of this contract and be entitled to receive the benefits of it the appellant was bound to give Mrs. M— the best treatment within his power and skill and to prolong her life as long as possible. Should he fail to do this either through neglect, by wilfully treating her in an improper manner or by directly causing her death appellant would be unable to recover upon the contract. There can be no doubt that a contract to commit murder, or any other crime, or a contract to give a reward to one for the commission of a crime, is void, as against public policy. This contract does not contemplate the commission of a crime or the doing of anything which is unlawful or contrary to good public morals. * * *

"There have been numerous decisions involving con-

"There have been numerous decisions involving contracts entered into whereby one party has agreed that upon his death his property of specific portions of it, shall go to and become the property of the other party for considerations named, being usually the caring for and maintaining of the guarantor during his or her lifetime by the other party, or whereby one party conveyed his property to the other for the consideration of the care, maintenance and support of the guarantor during the re-

mainder of his or her natural life, and these contracts have universally been held to be valid and building. In every such case the incentive to hasten the death of the guarantor was present to the same extent as in this case. While such contracts are usually made between parent and child or between others closely related by blood ties, they have been frequently made between persons who bear no blood relationship to one another and no distinction has been made by the courts on that ground."

The court also said

It is, therefore, not contrary to public policy to contract to devise property or to refrain from devising property for a consideration or to contract that property shall pass at once or at the decease of the grantor to the other party in consideration for the support care and maintenance of the grantor during the remainder of liss initial life by the other contracting party. So far as the question of an incentive to the commission of a crime is concerned, we perceive no difference between such contracts and the one here involved.

The further point was raised that the contract should be declared void for the reason that it was a wagering contract, and therefore illegal. The court discussed that theory by pointing out that the contract, even though unusual, was founded on consideration moving between the parties, that is, for money promised, the doctor had agreed to render actual professional services.

The decision of the court in upholding the validity of the doctor's claim is very similar to that in another case which came up, in which the bene ficury of a like arrangement was a hospital

In that case the patient was an elderly woman who had been suffering for a number of years from cancer of the breast. She had been operated upon on various occasions, but her case had been declared incurable. She had a son and two sisters living, but none of them was in a position to care for her. She went to a hospital and discussed with the proprietress the matter of making arrangements whereby the hospital would take care of her for the remainder of her days. An agreement was made to the effect that the woman

was to pay \$1,000 cash and to give a note for \$3,000, in return for which she would be furnished with a private room, board and care during her natural life. The cash payment was made, the woman entered the hospital and died in a week's time.

Thereafter suit was brought on behalf of the hospital to enforce the payment of the note by the pitient's estate. A jury awarded the hospital the amount sued for, and the matter was taken up on appeal. Similar objections to the validity of the contract were urged before the appellate court as in the ease above referred to, but the court again refused to prevent the enforcement of the contract, saying in its opinion.

'The appellee corporation was organized to conduct a liospital where it could care for the sick and afflicted It had full power and authority to make all contracts incident to the business in which it was engaged. It made the contract with Mrs. G because she was sick, needed care and had no place to go and no one to care for her. The contract was not in the nature of life insurance, was not a lottery, was not against public policy and was not ultravires. The question as to whether the contract was in fact entered into was one of fact for the jury. The question of the construction of the writing was one of law for the court. The contract was not void under the Statute of Frauds because it was in writing. As we have already held, the contract was a valid and substitutal obligation and nothing more need be said as to the last contention of the appellant."

In each of these cases there is no doubt that the beneficiary under the contract received a very handsome remuncration for the services rendered but these are not to be confused with instances of unfair dealings with aged and infirm wealthy individuals. In each case the elderly lady knew what she was bargaining for and received the benefits of the bargain, although death in each case cut down the amount of services that the doctor and the hospital, respectively, were obliged to provide to carry out their parts of the transactions.

NEWS NOTES

CIVIL WORKS ADMINISTRATION

A copy of the special rules and regulations promulgated by the Civil Works Administration to govern skilled work projects for nurses and other professional personnel engaged in medical relief has been mailed to the President of every county medical society in New York State, by Dr. J. S. Lawrence, Executive Officer of the Medical Society of the State of New York.

The Medical Director of the T.E.R.A., who is also representing the Civil Works Administration, is willing that the county societies should have an opportunity to express their approval or disapproval of the physicians who might be employed on local projects, and suggests the following regulation will be added giving County Societies an important share in the administration of the law:

"The Comitia Minora or the proper officers of each County Medical Society shall pass on the list of physicians submitted to them as applicants for employment in 'skilled work projects' as to their professional standing and economic status, in so far as it is related to eligibility for participation in such projects."

Physicians applying for work under the Civil Works Administration will be required to register in the rules; but naturally they will not need to qualify as indigents nor will their statements be checked up by inspectors. This is another reason why the county societies should have some supervisory power.

The special rules and regulations are as follows:

CIVIL WORKS ADMINISTRATION OF THE STATE OF NEW YORK

- SPECIAL RULES AND REGULATIONS GOV-ERNING SKILLED WORK PROJECTS FOR NURSES AND CERTAIN OTHER PROFES-SIONAL PERSONNEL ENGAGED IN MEDI-CAL RELIEF.
 - I. Scope—In general, the scope of skilled work projects for nurses and certain other medical relief workers shall be to augment and render more adequate facilities already existing in the community for the provision of bedside nursing and other professional care to indigent persons. Increased or additional nursing programs submitted as "Skilled Work Projects" should continue and supplement the work which has been according under the TERP A state which has been organized under the T.E.R.A. statewide work relief nursing service wherever such service exists.

II. PROGRAM OF WORK.

- A. For Nurses (Listed in order of importance).
 - 1. Bedside nursing care, for needy persons, to supplement existing community service. All calls from families on relief lists must be met before other services are rendered.
 - 2. Professional advice in homes, at request

- of Welfare Officials, particularly in relation to special health problems, such as diets for children, eare of pregnant women, and chronic illness.
- 3. Sift out calls for medical service by home visits so that every family needing medi-cal service will receive it, but unnecessary medical calls will be reduced to a mini-
- 4. Health instructions in the homes, to interpret instructions regarding budgets; diets; cod liver oil as a protective food; prenatal hygiene; need for immunization; arrangement for correction of defects where indicated and feasible.
- 5. Supplement the work of existing community agencies such as out-patient clinics and consultations conducted as part of the public health work of a community.

B. For Other Professional Personnel.

Programs adapted to the special needs of the community under the same general restrictions as to seope and services as indicated for nurses above.

Note-Special skilled work projects relating to public health will require nursing service in addition to existing service, and such service should be submitted as part of the special projects. Special proj-cets, as well as regular ones, should be integrated with a statewide program approved by the State Commissioner of Health.

- III. ELIGIBILITY (Subject to Requirements of "General Rules and Regulations Governing Skilled Work Projects No. II-A and II-B").
 - 1. Nurses. All nurses employed in their professional capacity in skilled work projects shall:
 - (a) Be licensed to practice as registered grad-uate nurses in New York State. First consideration shall be given to such nurses who have been residents, for not less than six months, of the welfare district for which the project is proposed. No persons, residents of the State of New York for less than six months, shall be eligible.
 - (b) Be employed as a T.E.R.A. work relief nurse during November, 1933, under the approved statewide project for work relief nurses; Or,
 - (c) Be certified as eligible for work relief by the chairman of the local, (city, county, or joint) emergency work relief bureau or the official responsible for such cer-tification under the local Civil Works Administration; Or,
 - (d) Be registered as unemployed in the local office of the N. Y. State Employment Service and/or the National Reemployment Service; And

(e) Be approved as to professional standing and fitness for the particular job by the

District State Health Officer.

2. Other Professional Personnel. Physicians and dentists employed in their professional capaci-

- ties in Special Skilled Work Projects shall:
- (a) Be licensed to practice their respective professions in New York State. First consideration shall be given to residents, for not less than six months, of the welfare district for which the special project is proposed. No persons, residents of the State of New York for less than six months, shall be eligible.
- (b) Be employed in their professional capacity, in a State or local work relief project approved by the T.E.R.A., during November, 1933; Or
- (c) Same as 1. (c) above.
- (d) Same as I. (d) above.(e) Same as I. (e) above.
- IV. RATES OF PAY AND HOURS OF WORK.

1. Nurses.

- (a) For nurses employed on T.E.R.A. work relief projects during November, 1933, sixty (60) cents per hour for forty hours per week. These nurses have been trained for this work and seliedules adapted to program of supervising agency. This basic program and staff shall be continued as a prerequisite to approval of increased or supplemental projects.
- (b) For nurses employed after December 1, 1933, to supplement existing work relief projects or for special nursing projects, sixty (60) cents per lour for a maximum of forty hours per week.
- (c) For specially qualified nurses employed after December 1, 1933, in a supervisory capacity in approved large scale skilled work nursing projects, seventy-five (75)

- cents per liour for a maximum of forty liours per week.
- Physicians approved and employed on a parttime basis in a skilled work project, after December 1, 1933, \$15 to \$35 per week depending on the hours of service.
- Dentists approved and employed on a part-time basis in a skilled work project after December 1, 1933, \$15 to \$35 per week depending on the liours of service.
- V. Approval. In order to coordinate all health activities in the State and local districts, skilled work projects for nurses and other professional personnel engaged in medical relief, shall meet the requirements of regulation I of the general "Rules and Regulations Governing Skilled Work Projects," and in addition shall be subject to the following procedure:
 - 1. Shall be approved in writing by the District State Health Officer. Such approval shall certify to: (a)—The need for additional bedside nursing or other professional service to augment or render more adequate local community services; (b) Adequate nursing or other professional supervision provided locally through existing visiting nursing associations; other accredited bedside nursing organizations; or through the Health Department; (c) Assurance that services provided through these projects would not supplant, but would augment existing services for the unemployed.
 - 2. Shall be forwarded by the local civil works administration to the Projects Division, State Department of Health, Albany, for approval and
 - 3. Shall be forwarded by the State Department of Health to the Projects Division, Civil Works Administration of the State of New York, 124 East 28th Street, New York City.

GENESEE COUNTY

The Economics Committee of the Genesee County Medical Society conferred with the County Welfare officer, and on July 1, 1933, reached an agreement regarding the medical care of the indigent. This agreement has been in operation since that date, and is being observed by the welfare officers of the county, and local districts, and by the physicians. While the agreement may not be all that is desired, yet the doctors are pleased to be recognized and to receive some pay for services which they formerly rendered free.

The agreement is as follows:

- 1. The family physician of the patient shall be employed as in private practice.
- The employment of a doctor shall be authorized by the Commissioner of Welfare, or one of his fifteen local deputies.
- 3. When a doctor is called to attend a patient under the Welfare Law, he shall at once notify

- the Commissioner or his deputy, and get a written authorization for his attendance. This authorization must be renewed every two weeks for continued attendance.
- 4. In an emergency case the physician shall give proper treatment at once; and within fortyeight hours he shall obtain the proper authorization for his treatment.
- 5. Additional authorization shall be obtained for unusual procedures, such as x-rays, laboratory analyses, consultations, and surgical operations.

A short fee list was adopted, including an office call \$1.00; house call \$2.00; and obstetric case \$25.00. The agreement closes with the following paragraph:—

In cases of dispute, the Economics Committee of the Genesee County Medical Society will act as a board of arbitration for the adjustment of the bills that are in dispute.

P. J. DINATALE, Secretary.

OUR NEIGHBORS

HEALTH INSURANCE IN MICHIGAN

The report of the survey of medical services in Michigan, made by a special committee of the Michigan State Medical Society, was reviewed in this Journal of September 1, 1933, page 1061. That report favored the general principle of health insurance, but the House of Delegates deferred approval of the report until further study. However, the House continued the committee which made a further study of health insurance and reported to another meeting of the House of Delegates, as follows:

"The committee defines health insurance as a device having for its purpose the equalization of the economic burdens of illness. To this end individuals make regular and definite contributions to a fund, and for these contributions receive stated medical services according to their needs. Thus medical care becomes a budgetable item in the costs of living. Viewed in this light it is seen that health insurance is not a device to reduce the costs of illness. In fact, the reverse would be true. The burden, however, would fall evenly upon many individuals rather than, as at present, upon a few.

"As pointed out in the report, certain grave defects are observable in health insurance systems in Europe. These observations resulted in the adoption of the previously mentioned policies by the House of Delegates. The hope of the profession in the United States lies in its ability to benefit from the experience and errors of the profession in other countries. Therefore, the Committee has devoted itself to the study of health insurance and now presents to the delegates the following series of steps which it regards as a logical sequence of action toward a plan or plans:

"1. The definition of the insured group of the population, according to income. The Committee feels that it now has sufficient data upon which to make a decision concerning the upper limit of income of the insured group. Such information includes income and cost of living data, as well as a knowledge of the incidence of sickness and the costs of medical care.

"2. The definition of 'family.' On the assumption that no plan of health insurance which excludes the family of the employed individual would be acceptable to either the profession or the public, the Committee proposes to define this social unit of the population. Such a definition is fundamental in that it will determine the number of people in the insured group.

"3. The determination of what medical services are to be provided. The Committee will attempt

to define as precisely as possible the service benefits to which the insured group shall be entitled.

"4. The determination of the probable need for services over a given period of time. Based upon items 2 and 3 the Committee will be able to work out its predictions of the need for medical services by the insured group. It is at this point that the Committee feels that it must exercise caution in making conservative estimates. Upon the conservatism of these estimates will depend the economic success of the program.

"5. The preparation of fee schedules. This step naturally follows the definition of the insured group, the designation of medical service, and the predictions of medical needs. The Committee will seek the aid of the members of the profession and the allied professions in the preparation of fee schedules for general practitioners, specialists, hospitals, laboratories, and any other services included under item three.

"6. The determination of the costs of medical care per family according to the fee schedules

adopted for the specified services.

"7. The organization and administration of the system. The policies already adopted by the House of Delegates must be given concrete form in this part of the plan. 'Free choice of physician,' 'professional control of services,' and the 'exclusion of commercial organizations' will be made a part of the plan of organization and administration. At the same time the Committee will secure advice concerning the legal status of health insurance so that the position of the profession may become clearly defined. Finally, the Committee will prepare estimates of the costs of administration.

"8. Estimates of total costs including the costs of services, the costs of administration, and any

reserves for emergencies.

"9. The presentation of the detailed data and plans to the House of Delegates. While the Committee hopes that it may proceed to this point without a special meeting of the House of Delegates, in all probability certain questions will require action by this body. To the end that any meeting shall be that of an informed body, the Committee will prepare progress reports during the course of its deliberations, for the individual delegates.

"10. The formal presentation of the plan or plans to induction and to the consumers of medical sery; any plan adopted must function through the consumers of medical sery; and the consumers of medical sery; and the consumers of medical sery; and the consumers of medical server.

pediatric hospitals where cod liver oil is administered as a food in a matter of fact manner, with the result that refusals are rarely encountered.

Most babies can be taught to take the pure oil if, as Eliot points out, the mother looks on it with favor and no unpleasant associations are attached in it. If the mother herself takes some of the oil, the child is further encouraged.

The dose of cod liver oil may be followed by orange juice, but if administered at an early age, usually no vehicle is required. The oil should not be mixed with the milk or the cereal feeding unless allowance is made for the oil which clings to the bottle or

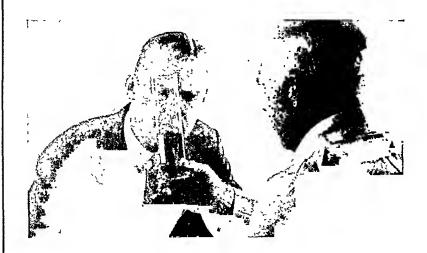

If given cold, cod liver oil has little taste, for the cold tends to paralyze momentarily the gustatory nerves As any "taste" is largely a metallic one from the silver or silver-plated spoon (particularly if the plating is worn), a glass spoon has an advantage.

MEAD JOHNSON & CO., Evansville, Indiana, U.S.A.

Some authorities recommend that edd liver oil be given in the morning and at bed time so as to assure an appetite for the oil, while others prefer to give it after meals in order not to retard gastric secretion. If the mother will place the very young baby on her lap and hold the child's mouth open by gently pressing the checks together between her thumb and fingers while she administers the oil, all of it will be taken. The infant soon becomes accustomed to taking the oil without having its mouth held open. Mead's Newfoundland Cod Liver Oil, of minimum acidity and prepared from fresh healthy livers, is well tolerated by infants and children and is palatable without flavoring. (To be continued)

Mead's 10 D Cod Liver Oil is made from Mead's Newfoundland Cod Liver Oil. In cases of fat intolerance the former has an advantage since it can be given in 1/3 to 1/2 the usual cod liver oil dosage.

RELIEF IN CYSTITIS

THE
RESULT OF
PYRIDIUM
ORALLY
ADMINISTERED

With the oral administration of Pyridium a clearing of cloudy urine may be expected in cases of urinary infection. Prompt relief of the distressing symptoms that often accompany such conditions as cystitis, pyelitis, and urethritis is usually obtained.

and the consumers of medical service, the Committee requests the approval of the House of Delegates for informal discussions with all groups concerned. For example, discussions with selected industrial leaders upon questions of payroll deductions, the attitude of industry toward contributions for extremely low income groups, the question of compulsion within an industry, and like problems, will have an important bearing upon the Committee's recommendations to the House of Delegates.

"11. The submission of the final plan to the House of Delegates." The President, Dr. J. M.

Robb, in his annual report said:

"This huge problem, with its smaller question of health insurance and its best solution, still confounds us. I am far from being convinced that all modern social tendencies are for the ultimate best. Does the 'sawdust trail' of health insurance lead to complete redemption from our medical ills? Is not the necessity for social insurance in direct proportion to the loss of moral responsibility on

the part of our people? Will health insurance increase our taxation; and if it does, will the public accept it?

"The report as presented by the special committee is the result of two years of prodigious, painstaking, persistent effort, and justly deserves a serious study and unselfish judgment by you.

"The logical solution of the problems of medical economics depends upon the solution of general economics. If the state is to control industry, it will and probably should control medicine. You will note, however, that in the formation of the National Recovery Act the principle, upon which it was based, was not insurance, but the re-establishment of the responsibility and independence of the individual.

"Whatever scheme or system be presented, it is not an end in itself, but a means to an end. It behooves us, therefore, to continue our local study and carefully analyze the set-up of social structures,—in other nations, selecting for our guidance that which is good, and discarding, that which contributes to the degradation of those nations."

PUBLIC HEALTH WORK IN GEORGIA

An editorial in the October number of the Journal of the Medical Association of Georgia has the following account of the reduction in

the resources of the Department of Health of the State:

(Continued on page 1472-adv. xiv)

HOW the findings of

X-RAY

DIFFRACTION RESEARCH are applied to Curity

Suture Manufacture

Curity has adopted X-Ray Diffraction technique for use in research on catgut structure. In the Curity laboratories it has revealed, for the first time, the ultimate structure of catgut. This new knowledge has enabled Curity scientists to more accurately control the processing of the raw enignt, to produce a suture of more dependable tensile strength and absorption characteristics.

New facts on catgut structure and the effect of structure on beliavior, under given conditions, are constantly being discovered by X-Ray Diffraction research in the Curity laboratories. These facts form the basis for improvement of the Curity manufacturing process, which is constantly progressing toward a higher standard of suture quality.

(Continued from page 1470-adv. xii)

"Dr. T. F. Abercrombie, State Commissioner of Health, today announced a curtailment of all activities of the State Department of Public Health on account of a drastic cut made in the state health budget for the last quarter of this year ending December 31.

"Sixteen employees of this department have been advised that it will be necessary to discontinue their services for the months of November and December. The releasing of these employees will cause the department to be greatly handicapped in carrying on many of the essential activities necessary for the protection of the health of the citizens of this state. The releasing of these employees will also cause the greater part of the field work which has been established in recent years to be abandoned. Every division of the Health Department has been required to release some members of their personnel.

"As the demands upon the Division of Laboratories during recent years have been so great that the personnel was not able to keep up with the amount of work demanded of them, the loss of some of the personnel in this division will necessitate the department's making a complete change in the policies that they have adhered to in the past. With the exception of the handling of the specimens for the diagnosis of the common communicable diseases, which include typhoid, diphtheria, malaria and intestinal parasites, it will probably be necessary to charge a small fee for all laboratory examinations.

"The Division of Vital Statistics has been compelled to release practically one-half of its personnel and this work which deals with the filing and recording of the birth and death records of the state will be seriously handicapped.

"The Division of Sanitary Engineering will be forced to release all field engineers and if some plan is not worked out to continue the service of sanitary engineering in the malarial sections especially, this work will suffer a severe handicap. With more than forty cities already requesting financial assistance from the United States Government for municipal improvements, a curtailment of the engineering division will cause a delay in the approval of the plans for the improvement of the water and sewerage systems.

"The Division of Child Hygiene will release all of its field nurses who have been devoting their entire time to improving health conditions for the mothers and babies in the state."

The editorial closes with a ray of hope that the appropriations will be restored after January first.

MEDICAL EXHIBIT IN INDIANA FAIR

The October issue of the Journal of the Indiana State Medical Association carries a description of a Good Health Exhibit conducted

(Continued on page 1473-adv. xv)

(Continued from page 1472-adv. xiv)

by the Indiana State Medical Association in Indianapolis, September 2-8, 1933. The article says:

"Six of the leading health agencies of the state co-operated with the State Association to make the scientific and educational exhibits housed in the 'Good Health Building' on the Fair Ground one of the outstanding features of this year's fair. The purpose of the displays was to show the public the methods and ideals of scientific medicine and its related branches. It is estimated that 25,000 persons visited the exhibit during the week.

"Under the direction of the Indiana State Dental Society, 'Jimmy Chew', the famous dental pupper show, imported especially for the occasion from the Century of Progress Exposition in Chicago, drew some nine thousand spectators as a total of its three daily performances throughout the week.

"The Indiana Hospital Association, the Indiana Tuberculosis Association and the Indiana Pharmaceutical Association all had interesting and elaborate displays, and the Indiana State Nurses' Association was in charge of the children's playgrounds adjacent to the State Board of Health and the Good Health Buildings.

"High blood pressure was the primary point of emphasis of the combined exhibits of the American Medical Association and the Indiana State Medical Association. Through the courtesy of the Teylor Instrument Company, of Rochester, New York, a new type Tycos self-recording sphygmomanometer was obtained and over 2,500 blood pressures were taken. Three times as many tests could have heen run with additional equipment, as interest was very great in the procedure and there always was a crowd around the machine. Each visitor tested was allowed to keep his chart, and in the event that the blood pressure was abnormally high it was suggested that he call upon his family physician and show the chart to him. Tact was exercised not to alarm any person, but in these instances the family physician was notified of the person's name and the pressure obtained.

An excellent array of pathological specimens obtained from the medical school was exhibited. These specimens showed the changes which occur as a result of neglected high blood pressure.

"The remainder of the space in the exhibit was devoted to displays concerning patent medicines and quackery and the dangers of self-diagnosis. Some forty posters were shown bearing the names and descriptions of many popular nostrums. Twenty different pamphlets dealing with various types of quackery were available and were eagerly read by the visitors who filled the booth most of the time.

(Continued on page 1474-adv. xvi)

MALNUTRITION

-especially in children who dislike milk

WillLE malnutrition in children may be due to premalure birth, to some constitutional debility or the development of some serious disease, the great majority of cases are due to improper or faulty diet.

Insufficient milk is by far the most serious failing in children's diets. This is due, no doubt, to the fact that so many youngsters dislike milk and refuse to drink it. More and more physicians are meeting this problem by prescribing Cocomalt—which is as alluring as chocolate soda to children.

Prepared as directed, Cocomalt adds 110 extra calories to a cup or glass of milk—increasing the protein content 45%, the carbohydrate content 184%, the mineral content (calcium and phosphorus) 48%. It is rich in Viamin D, containing no less than 30 Steenbock (300 ADMA) units of Vitamin D per ounce—the amount used to make one drink. (Licensed by Wisconsin University Alumni Research Foundation.)

This rich Vitamin D content, combined with the extra calcium and phosphorus provided by Cocomalt and milk, aids substantially in the development of strong bones and sound teeth.

At grocery and drug stores in ½-lb. and l-lb, vacuum sealed cans. Also in 5-lb. cans for hospital use, at a special price. R. B. Davis Co., Hohoken, N. J.

Cocomalt is accepted by the Committee an Foods of the American Medical Association

Cocomalt is composed of sucrose, skim milk, selected cocoa, barley malt extract, flavoring and added Vitamin D.

Always the key question about Cod Liver Oil

IFFERENT eod liver oils unquestionably vary in vitamin potency, due to differences in the quality of fish, the methods of obtaining the oil, and its preparation and protection.

Every physician is entitled to know two things about any brand of cod liver oil before he specifies it.

- 1. What is its vitamin content?
- 2. How is this protected?

These questions can be quickly and satisfactorily answered about Puretest Cod Liver Oil.

Purctest guarantees a Vitamin A content of not less than 50,000 U.S.P. units in each 100 grams.

It guarantees not less than 13,333 Oslo units in each 100 grams.

This rich vitamin content is always stable because it is protected from deterioration caused by oxidation. Before the containers are filled with oil, all air is forced out by filling with nitrogen gas.

When you advise cod liver oil for your patients, remember these important facts about Purctest. You can specify it without reservation.

COD LIVER OIL

UNITED DRUG CO., BOSTON, MASSACHUSETTS

(Continued from page 1473—adv. xv)

"A space was devoted to the health magazine, *Hygeia*, and visitors were informed as to its interesting and educational articles which discuss health problems.

"Two medical students, Oren Kay and Hugh Martin, operated the blood pressure machine and kept accurate records of every case.

"Some interesting statistics were obtained. The average State Fair visitor during the last days was 41.2 years of age, weighed 153.9 pounds, and had an average blood pressure of 145.9 systolic and 91.2 diastolic. These figures represent a composite picture of the 2,500 blood pressures taken. The highest systolic blood pressure was 320, lowest systolic blood pressure was 90. The highest diastolic blood pressure was 175, the lowest diastolic pressure was 50. Blood pressures taken during the four days are somewhat above the average, probably because of the exercise and excitement incident to attending the State Fair."

PUBLIC HEALTH COOPERATION IN MISSOURI

The October issue of the Journal of the Missouri State Medical Association prints the following invitation from Dr. E. T. McGaugh, State Health Commissioner, that the State Medical Association cooperate with the Department of Health:

"I am informed that you have kindly offered space in The Journal for health news and health comments from the State Health Department. This is most generous and I am sure will be helpful to both the Department of Health and to physicians.

"It is the desire of the department that every consideration be extended to the physicians of the state. Misunderstandings that have arisen in the past can be prevented in the future if the health program is planned jointly. To cement a closer working arrangement it is recommended that a public health committee composed of medical leaders be appointed by the State Medical Association to aid the Department of Health in analyzing problems which are medical in nature. Definite plans should be perfected suitable to both the physicians and the health organizations before beginning any innovations in health administration or in health procedure."

REPORTS OF COMMITTEE ACTIVITIES IN COLORADO

The solution of the problem of informing the members of State Medical Societies regarding the

(Continued on page 1475-adv. xvii)

(Continued from page 1474-adv 221)

work of the State Committees is as difficult in Colorado as elsewhere, judging by the following editorial in the November issue of Colorado Medicine:

"This year it will be a policy of the "Secretarial Notes" section of Colorado Medicine to publish more details of State Society committee work than has been done before, under a recommendation of the House of Delegates. Members are therefore uiged to watch these pages each month to learn what their committees are doing to advance the interests of the individual practitioner.

"Within the last twelve mouths it has become apparent to the officers that many members realize but little of what goes on under the direction of the Society's many officers and committees. The expense of periodic bulletius to members outlining State Society activities would be prohibitive in these times, yet some way needs to be found to let all physicians know more about the tireless work put in by committeemen toward bettering conditions of practice, improving the economic position of doctors, protecting members from mfringement of their rights and privileges. Much committee work is of necessity 'behind closed doors' and cannot be published in a journal that must reach non-members, but much more can be published than has been in the past

"In the thirty days preceding this writing, meetings and conferences have been held by the committees on Scientific Work, Public Policy, Publication (two meetings), Medical Defense (two meetings), Medical Economics, Advisory to the School of Medicine, and Cancer Education (two meetings). Other meetings are under call. Reports from the chairmen of two of these committees are presented this month. Both are highly important. Read them, and watch for more next

month."

CANCER DIAGNOSTIC CLINICS IN ILLINOIS

The editorial section of the November issue of the Illinois Medical Journal has the following suggestion regarding cancer diagnostic clinics to be conducted by county medical societies:

"The organization of the crusade against cancer must be based mainly on a wide publicity campaign and on the constant training of the physician. Histopathologic research is necessary for the purposes of early diagnosis and can be managed by the pathologist of any well organized hospital. An annual toll of 200,000 persons is to be regarded as the basic figure in this country and therefore every county medical society in our state should have a tumor clinic at one or more hospitals as part of their work for cancer control. Such a group staffed by some of their own con-

freres especially interested in cancer clinics and tissue diagnosis will be fascinating and helpful to all, and lead to the early use of surgical intervention or the application of physical agents.

"These clinics being a part of the society's activities can be operated uniformly in an advisory capacity only, if desired, without financial gain to the sponsoring institution and without expense to the patient or the referring physician. They may meet once or twice a month, depending on the size of the hospital and the material available. Such tumor clinics will increase the knowledge and the capacity of a large group of physicians and also of many institutions and thus carry on research with greater facility and at a minimal expense. If you haven't a cancer clinic in your county medical society, why not? At this time, when we are not so busy, these clinics will not only be taken care of easily, but can be in the nature of a past graduate course along cancer lines."

THE PENNSYLVANIA JOURNAL

It is interesting to note the ideals and policies which are formulated by the official journals of the medical societies of the several states. Although the journals cover the same field, each one has its own individuality of content and make-up. The October issue of the *Pennsylvania Medical Journal* has the following editorial comment on the beginning of the thirty-seventh year of its publication:

"The Pennsylvania Medical Journal was founded in 1886 by Dr. X. O. Werder as the Pittsburgh Medical Review, and conducted by an editorial board. In 1892, the late Dr. Adolph Koenig, of Pittsburgh, assumed the editorship, and in 1897 the name was changed to the Pennsylvania Medical Journal, and it became the first state medical journal in America.

"This is the house organ of your State Society, covering the activities of the parent organization and its component county societies. It also affords much valuable information of allied interest."

Regarding reports of meetings of county medical societies an editorial says:

"We wish to extend grateful appreciation to the official reporters of the component county medical societies of our State Society, who forwarded to the Journal office during the fiscal year reports of the meetings of their county societies. There has been an increase in the number of reports received in comparison with the previous year, notwithstanding a few have become inactive, and some have never begun. We are also indebted to those

(Continued on page 1477-adv. xix)

(Continued from page 1476-adv. xviii)

who have sent reports of other medical meetings. It should be of interest to the reporters to know that during the fiscal year just closed 178 county society reports were published. If the report of a county society does not appear in the Journal it is because the report has not been received in the Journal office.

"Frequently a meager death notice is given of a deceased physician in the Journal. This is because the Journal office has no data in regard thereto.

"Please bear in mind we do not publish resolutions adopted in memory of deceased physicians. During the past fiscal year our State Society sustained a loss of 130 members, an average of 10 plus a month. It readily can be appreciated the amount of space that would be utilized for this purpose."

The Pannsylvania Journal also publishes news of a personal nature:

"Other matters of interest for news items that the reporter could bear in mind are: births, engagements, marriages, death of members of a doctor's immediate family (wife, children), and other local medical activities."

When Phillips' Milk of Magnesia Tablets are prescribed you are certain that your patient is receiving the purest of ingredients in the amount specified.

inaccuracies in the various household methods of measuring are likely to lead to poor results if an improper dosage is received. This is avoided by preacribing tablets.

Each tablet of Phillips' Milk of Magnesia contains in concentrated form a teaspoonful of liquid milk of magnesia, thus simplifying the dosage.

The pleasant taste, convenience of taking and obsence of unpleasant after-effects all combine to appeal to your patient's comfort.

For those who travel, especially, you will find that Phillips' Milk of Magnesia Tablets supply a long-felt want.

NEW PRODUCT FOR DIPH-THERIA IMMUNIZATION

The Squibb Laboratories announce the availability of Refined Diphthcria Toxoid Alum Precipitated with the featured advantage that one injection is sufficent for the immunization of the majority of children against diphtheria. The efficacy of the preparation in immunizing against diphtheria is believed to be due to the fact that the alum precipitated toxin, since it is relatively insoluble, is more slowly absorbed and remains in the body sufficiently long to produce adequately protective amounts of antitoxin

One injection of Alum Precipitated Toxoid is reported to be as effective as two or three injections of ordinary unprecipitated toxoid, and is also

122 E. 25th St., New York, N. Y. STuyvesant 9-0280

said to produce a greater number of negative Schick Tests, that is, a higher percentage of immune individuals. These features make Alum Precipitated Toxoid of particular value in public health work, for two or three times as many persons may be immunized with no more effort nor time on the part of the public health worker. It also makes it easier for the family physician to follow the advocated procedure of immunizing every infant, at whose birth he has officiated, at 6 months of age.

Squibb Refined Diphtheria Tox-

Squibb Refined Diphtheria Toxoid Alum Precipitated is prepared according to the method reported by the Alabama Board of Health for a single-dose treatment. It is marketed in 0.5 cc. vials for immunization of one person, and in 5 cc. vials containing sufficient material for the immunization of ten individuals.—Adv.

VITAMIN D

It has been estimated that in many cities in the temperate zone, fully 90% of the child population shows the effect of vitamin D deficiency in bone and tooth development.

There is no appreciable amount of vitamin D in common articles of food; but by drinking delicious chocolate flavor Coco-malt every day, a growing child is definitely safeguarded from a vitamin D deficiency.

For vitamin D is present in Cocomalt in the proportion of 30 Steenbock (300 ADMA) units per ounce—the amount used to make onc drink. Mixed with milk according to directions, every cup or glass of Cocomalt a child drinks is equivalent in vitamin D content to two-thirds of a teaspoonful of good cod-liver oil.

Many physicians recommend Cocomalt routinely during pregnancy and lactation, not only because of this rich vitamin D content, but because of the extra proteins, carbohydrates and minerals (calcium and phosphorus) which Cocomalt provides.—Adv.

KALAK WATER

Many diseases are complicated by an "acidosis." An important part in their treatment consists in replacing those elements needed to maintain the alkali reserve.

In clinical practice a rational and agreeable method of alkalinization is afforded in Kalak Water.—Adv.

CREST VIEW SANATORIUM

Charmingly located, beautifully appointed; in the hilly country one and a half miles from Long Island Sound where the air is tonic. Quick drive from New York City. Truly homelike, no institutional appearance.—Adv.

The VEIL Maternity Hospital

WEST CHESTER, PENNA.

For Care and Protection of the BETTER CLASS UNFOR-TUNATE YOUNG WOMEN

Strictly Private. Absolutely Ethical. Patients accepted at any time during gestation. Open to Regular Practitioners. Early entrance advisable.
